Received: 24 June 2018; accepted: 15 August 2018

Two pairs of homoisoflavonoid analogues, 6-aldehydo-isoppiophoagusnone A (1) / 6-aldehydo-isoppiophoagusnone B (2) and methylophiopogonanone A (3) / methylophiopogonanone B (4), were obtained from the fibrous roots of Ophiopogon japonicus (L. f.) Ker-Gawl. (FROJ) by silica gel column chromatography (SGCC) and recycling high-speed counter-current chromatography (rHSCCC). First, the ethyl acetate fraction from the 70% ethanol extract was pre-separated by SGCC with a petroleum ether-ethyl acetate gradient (50:1–21, v/v). Then, the two subfractions containing homoisoflavonoid analogues were further separated by rHSCCC with n-hexane-ethyl acetate–methyl–acetonitrile–water (3:2:5:1:1.5, v/v) and n-hexane-ethyl acetate–methyl–acetonitrile–water (3:2:5:1:1.5, v/v). Finally, 6-aldehydo-isoppiophoagusnone A (16 mg), 6-aldehydo-isoppiophoagusnone B (26 mg), methylophiopogonanone A (46 mg), and methylophiopogonanone B (148 mg) were obtained with purities of 97.82%, 96.70%, 97.76%, and 94.62%. Their structures were identified by high-resolution quadrupole-time-of-flight mass spectrometry (HR-QTOF-MS), ultraviolet (UV), and nuclear magnetic resonance spectroscopy (\textsuperscript{1}H-NMR and \textsuperscript{13}C-NMR). These results demonstrated that HSCCC could be used for the large scale preparation of homoisoflavonoid analogues from FROJ, which provides scientific support for utilization of untraditional medicinal part of O. japonicus and also for reduction in waste of plant resources. Additionally, an online antioxidant activity assay was investigated with hyphenated HSCCC-DPPH (1-diphenyl-2-picrylhydrazyl) radical scavenging detection.

Keywords: Ophiopogon japonicus, fibrous roots, homoisoflavonoid analogues, column chromatography, recycling high-speed counter-current chromatography, online antioxidant activity

1. Introduction

The tuberous roots of Ophiopogon japonicus (L. f.) Ker-Gawl. (known as Maidong) have been used in traditional Chinese medicine to cure acute and chronic inflammation and cardiovascular diseases for thousands of years [1–3]. Moreover, O. japonicus is also considered a functional food in China, Japan, and some south-eastern Asian countries [4]. Homoisoflavonoids, steroidal saponins, and polysaccharides are the main active constituents of O. japonicus [4–6], and homoisoflavonoids exhibit various pharmacological activities such as anti-oxidation [7–9], anticancer [10–12], anti-inflammatory [2, 13, 14], and cardiovascular protection [15–17]. Usually, the valuable fibrous roots of O. japonicus (FROJ), about 40% of total roots weight, is discarded when the medicinal part of the tuber roots is collected. Recently, several homoisoflavonoids [7, 10] and steroidal saponins [1, 18–24] have also been purified from FROJ, which could be an important resource for bioactive natural products. Li et al. [25] found that the saponin content in FROJ was higher than that in tubers, and the FROJ can be an important saponin source in this plant. Homoisoflavonoids, a special type of flavonoids containing one additional carbon atom compared to isoflavonoids, show smaller polarity and poorer solubility in methanol or acetonitrile than other flavonoids. Due to the close polarity of homoisoflavonoid analogues, their large scale separation is relatively difficult, only by silica gel column chromatography (SGCC) or preparative high-performance liquid chromatography (HPLC).

High-speed counter-current chromatography (HSCCC) is an effective chromatographic separation and preparation technology that is based on continuous liquid–liquid partition [26], which has many advantages such as high load capacity, cheap liquid stationary phase, and low solvent consumption [27]. Recycling high-speed counter-current chromatography (rHSCCC) is one development of elution modes in the recent years [28], has been successfully used for some chiral compounds [29] and natural analogues [30–35], and can improve the separation factor through the cycling the elution in the column. In addition, an online HSCCC-antioxidant activity assay will be a useful technique to screening and preparative isolation of antioxidant components from medical plants. Nevertheless, only Shi et al. [36] has successively used this assay for simultaneous preparative isolation and screening of antioxidants from Selaginella moellendorfii in online coupling way. The method enabled rapid screening of antioxidant components without the need for off-line evaluation of their activity.

In the present study, we developed a new application to obtain two pairs of homoisoflavonoid analogues (Figure 1) by SGCC and rHSCCC from FROJ. This technique provides scientific support for utilization of different parts of the medicinal plant O. japonicus, and also for reduction in waste of plant resources. Moreover, an online antioxidant activity was...
investigated with hyphenated HSCCC-DPPH (1-diphenyl-2-picrylhydrazyl) radical scavenging detection.

2. Experimental

2.1. Apparatus. Ultrasonic-assisted extraction was carried out using a digitally controlled ultrasonic bath (KQ-300DE, Kunshan Ultrasonic Instruments Co., Ltd., China). The HSCCC systems were comprised of a TBE-300A module, a TBPS02 constant-flow pump, and a ultraviolet (UV) monitor (Tauto Biotechnique Company, Shanghai, China). The TBE-300A module was equipped with 3 polytetrafluoroethylene preparative coils (2.6 mm, i.d.; total volume, 300 mL) and a 20-mL sample injection loop, and the revolution speed could be adjusted in the range from 0 to 1000 rpm. A constant temperature regulator (HX-105, Beijing Changliu Science Implement, China) was used to control the temperature of the separation coils. HPLC was performed on a Shimadzu LC-20AD separations module connected to a SIL-20A auto sampler, a CTO-20A column oven, and a SPD-20A UV/visible detector (Shimadzu Corporation, Japan). The UV spectra were analyzed with a UV-2600 spectrophotometer (Shimadzu Corporation, Japan).

2.2. Reagents and Materials. The HPLC-grade acetonitrile was obtained from the TEDIA Company, Inc. (Fairfield, OH, USA). DPPH (97%) was purchased from TCI (Fairfield, OH, USA). The other solvents utilized for the separation and purification of the FROJ were all of analytical grade and were bought from Shanghai Lingfeng Chemical Reagent Co. Ltd., China. The pure water used in this study was produced by a Direct-Q water system (Millipore, Bedford, MA, USA). The chromatographic silica gel and TLC plate were purchased from Qingdao Ocean Chemical Factory (Qingdao, China). The FROJ was collected in 2014 from Shengshan Town, Cixi City (Zhejiang province, China) and was authenticated by Professor Jianwei Mao (Zhejiang University of Science and Technology, Hangzhou, China). The voucher specimens (No.201405) were deposited in Zhejiang Provincial Key Laboratory for Chemical and Biological Processing Technology of Farm Product, Zhejiang University of Science and Technology, Hangzhou, China.

2.3. Preparation of the Crude Extract. The dried FROJ (1 kg, 60 mesh) were ultrasonic-assisted extracted two times with 10-fold amounts of 70% ethanol. The extracts was immediately concentrated, and a brown syrup (448 g) was obtained. Then, the syrup was suspended in water and successively extracted using petroleum ether, ethyl acetate, and n-butanol. The ethyl acetate layer was concentrated to dryness in a rotary evaporator, and the dried ethyl acetate extract (9 g) was obtained and stored at 4 °C prior to separation.

2.4. Pre-Separation of the Crude Extract by SGCC. The silica gel (200 g, 200–300 mesh) was suspended in petroleum ether (500 mL, 60–90 °C), and then transferred to a glass column (80 cm length × 5 cm i.d.). The ethyl acetate fraction from the FROJ (8 g) was first dissolved in ethyl acetate (30 mL) and mixed with silica gel (10 g). Then, this dry sample was subjected to the silica column after ethyl acetate was removed on a water bath at 50 °C. Secondly, the SGCC was eluted with petroleum ether (60–90 °C)-ethyl acetate gradient (50:1, 20:1, 10:1, 5:1, and 2:1, v/v). Eluents of 100 mL each were analyzed on GF254 TLC plates at room temperature, using petroleum ether–ethyl acetate (4:1, v/v) as the developing reagent. Spots were visualized under an ultraviolet lamp at 254 nm and 5% FeCl3–EtOH (v/v) color development reagent. The eluates containing similar spots were merged into one sub-fraction and concentrated in the rotary evaporator. The target sub-fraction containing the two pairs of homoisoflavonoid analogues was stored in a desiccator for the subsequent HSCCC separation.

2.5. Further Separation by rHSCCC

2.5.1. Measurement of the Partition Coefficient (Kv). The selected two-phase solvent systems were prepared and equilibrated for the investigation of the partition coefficient. Two milliliters of each phase were transferred into a 10-mL test tube, in which 1 mg of the target sub-fraction from SGCC was placed in beforehand. When the two phases were thoroughly equilibrated after shaking vigorously, 1 mL solution taken from each phase was filtered through a 0.45-μm membrane and analysed by HPLC. The Kv value was defined as the ratio of the peak area in the upper phase and the lower phase of a given compound. The separation factor (αv) was calculated using the ratio of Kv values of two homoisoflavonoid analogues.

2.5.2. Preparation of HSCCC Solvent System and Sample Solution. The two-phase solvent system finally applied for rHSCCC was composed of n-hexane–ethyl acetate–methanol–acetonitrile–water (HEAMW, 3:2:3.5:1:0.5, v/v) and HEAMW (3:2:2.5:1:1.5, v/v), respectively. The upper phase (stationary phase) and the lower phase (mobile phase) were separated in a separation funnel and degassed by ultrasonication for...
30 min shortly prior to use. Sample solutions of sub-fraction 7 (49 mg) and sub-fraction 8 (257 mg) from SGCC for rHSCCC separation were prepared by dissolving the sample in a 10-mL solvent mixture of both phases, respectively.

### 2.5.3. rHSCCC Separation Procedure.

Because homoisoflavonoid analogues have similar $K$ values, the classical elution mode of CCC cannot achieve satisfactory resolution. The rHSCCC was carried out by connecting the outlet of the detector to the inlet of the pump. The experimental process was performed as follows. First, the HSCCC column was filled up with the upper stationary phase of the solvent system at 20 mL/min. Then, the lower mobile phase was pumped into it at 2.0 mL/min when the column rotated speed reached 900 rpm. Second, the sample solution was injected into the column after the hydrodynamic equilibrated. Third, the recycling elution mode was performed by channeling the outlet of the detector to the inlet of the pump with a pipeline shortly before the first cycle elution started. When the target sample was separated after two HSCCC cycles, the recycling elution was stopped by disconnecting the pipeline to conventional HSCCC. Finally, the target compounds were collected manually according to the chromatograms at a wavelength of 285 nm.

### 2.6. HPLC Analysis.

The HPLC method was used to analyze the homoisoflavonoids from the fibrous roots isolated by SGCC and HSCCC after some modifications [35]. The separation was performed on a Shimadzu C18 column (5 μm, 250 mm × 4.6 mm). The volume ratio of mobile solvents A (water) and B (acetonitrile) was kept at 35:65, and the temperature was set at 30 °C. The flow rate of the mobile phase was 1 mL/min. The detection wavelength was monitored at 285 nm.

### 2.7. Online Antioxidant Activity Assay.

An online detection of antioxidant activity for sub-fraction 8 in the ethyl acetate extract of FROI was developed by combining HSCCC with online radical scavenging using DPPH as the model radical. The HSCCC system conditions were the same as the previous separation procedure, and the post-column effluent from HSCCC was mixed with the DPPH reagent.

![Figure 2](image-url)

**Figure 2.** HPLC chromatograms of different fractions from the fibrous roots of *O. japonicus*: (A) the ethyl acetate fraction, (B) sub-fraction 7 from ethyl acetate fraction by SGCC, and (C) sub-fraction 8 from ethyl acetate fraction by SGCC. HPLC conditions: Shimadzu C18 column (5 μm, 250 mm × 4.6 mm); temperature = 30 °C; mobile phase: water and acetonitrile (35:65, v/v); flow rate = 1 mL/min; detection wavelength = 285 nm. Peaks: 1 = 6-aldehydo-isophiopogonanone A; 2 = 6-aldehydo-isophiopogonanone B; 3 = methylophiopogonanone A; 4 = methylophiopogonanone B
using a Shimadzu LC-20AD pump module and a SPD-20A UV/visible detector. The sample (50 mg) was injected into HSCCC system and detected at 285 nm. The HSCCC-separated components reacted post-column with DPPH at a concentration of 50 μmol/L in methanol. The flow of the reagent solution was set to 1 mL/min. The online antioxidant activity assay was detected at a variable wavelength of 517 nm as a negative peak. The length of the tube used for the post-column reaction was 9 m to achieve a sufficient reaction time.

3. Results and Discussion

3.1. Pre-Separation by SGCC. As shown in Figure 2A, 6 obvious chromatographic peaks can be found from 6 min to 15 min in the ethyl acetate fraction. After eluting with a petroleum ether (60–90 °C)–ethyl acetate gradient by SGCC, the ethyl acetate fraction (8 g) was pooled to 20 sub-fractions (sub-fraction 1–20) according to their TLC profiles. Sub-fraction 7 (312 mg) and sub-fraction 8 (494 mg) with the same single TLC spot have two pairs of homoisoflavonoid analogues and were further verified by HPLC (Figures 2B and C). However, the poor solubility in methanol or acetonitrile of these homoisoflavonoid analogues could not be isolated on preparative HPLC. Due to the failure to separate the two pairs of homoisoflavonoid analogues by preparative HPLC and repeat SGCC, HSCCC was tried in our further experiment.

3.2. Selection of Two-Phase Solvent System. The most important step for successful separation by HSCCC is finding a suitable two-phase solvent system. In view of the solubility and polarities of the target compounds, the combination of hexane-ethyl acetate–methanol–water (HEMW) was chosen as the initial biphasic system according to the Ito’s work [26], starting with n-hexane–ethyl acetate–methanol–water (HAMEW, 4:5:4:5) to 10:0:5:5, v/v with increasing order of hydrophobicity of their organic phases. As shown by No. 1 to 6 in Table 1, the four homoisoflavonoids tended to dissolve well into the organic phase with high K values. Therefore, the volume ratios of n-hexane versus ethyl acetate and methanol versus water were adjusted to change K values. When n-hexane versus ethyl acetate was fixed at 3:2, the K values were largely reduced with increasing proportion of methanol (Table 1, No. 7–9). When n-hexane versus ethyl acetate was changed to 2:3, the K values of four compounds could be between 0.5 and 2 (Table 1, No. 10–12). However, the values α12 and α34 were <1.5. According to the reference of HSCCC [37], acetonitrile is added into the volume ratio of n-hexane versus ethyl acetate at 2:3; α12 and α34 increased to approximately 1.2, with acceptable K values from 0.5 to 1 for rHSCCC (see Table 2). Thus, the solvent systems of HEAMW at 2:3:2:5:1:0.5 and 3:2:2:5:1:1.5 were selected for subsequent HSCCC separation.

3.3. rHSCCC Separation and HPLC Identification. HSCCC is a useful methodology to improve the chromatographic resolution among compounds with similar partition coefficients, which is extremely suitable for the separation of analogues. The resolution of analogues will increase after each cycle, but the solvent consumption remains the same. As shown in Figures 3A and B, the two peaks overlapped seriously in the first cycle; nevertheless, the second separation cycle exhibits a better separation; thus, the rHSCCC was returned to normal elution. Finally, the two pairs of peaks with 4 compounds were well separated and collected in the third cycle. The retention ratios of the organic stationary phase for the two rHSCCC were approximately 55% and 58%, which were calculated from the volume of the stationary phase collected from the column after the separation was completed. As shown in Figure 4, compound 1 (16 mg), 2 (26 mg), 3 (46 mg), and 4 (148 mg) were obtained with purity of 97.82%, 96.70%, 97.76% and 94.62%, respectively, after the recovery of organic solvents.

3.4. Structural Identification of Isolated Compounds. Compounds 1–4 were purified as colorless needle crystals. The structural illustration of 4 compounds from the FROJ was carried out by UV and QTOF-MS (shown in Table 3), and NMR spectra were listed as follows.

Table 1 The K and α values of 4 compounds in HEMAW systems

| Solvent ratio | K1 | K2 | α12 | K3 | K4 | α34 |
|---------------|----|----|-----|----|----|-----|
| 1             | 4:5:4:5 | –  | –  | 45.9 | 49.3 | 1.07 |
| 2             | 5:5:5:5 | –  | –  | 20.6 | 21.1 | 1.02 |
| 3             | 6:4:5:5 | –  | –  | 17.6 | 18.5 | 1.05 |
| 4             | 7:3:5:5 | –  | –  | 16.1 | 17.3 | 1.07 |
| 5             | 8:2:5:5 | –  | –  | 12.9 | 14.4 | 1.11 |
| 6             | 10:0:5:5 | 71.7 | 54.4 | 0.75 | 12.7 | 14.5 | 1.14 |
| 7             | 3:2:3:2 | 17.7 | 20.7 | 1.17 | 4.29 | 4.53 | 1.06 |
| 8             | 3:2:3:1.5 | 6.24 | 7.50 | 1.20 | 1.44 | 1.62 | 1.12 |
| 9             | 3:2:4:1 | 2.30 | 2.70 | 1.17 | 0.60 | 0.66 | 1.10 |

| 11            | 2:3:3:2 | 3.66 | 4.01 | 1.10 | 1.50 | 1.57 | 1.05 |
| 12            | 2:3:3:1 | 1.59 | 1.75 | 1.10 | 0.59 | 0.63 | 1.08 |

αHexane-ethyl acetate–methanol–water.

Table 2 The K and α values of 4 compounds in HEMAW systems

| Solvent ratio | K1 | K2 | α12 | K3 | K4 | α34 |
|---------------|----|----|-----|----|----|-----|
| 1             | 3:2:2:1:2:1 | 9.56 | 12.4 | 1.30 | 2.55 | 2.88 | 1.13 |
| 2             | 3:2:2:5:1:1.5 | 3.29 | 4.14 | 1.26 | 0.81 | 0.94 | 1.16 |
| 3             | 3:2:2:5:1:1.5 | 1.47 | 1.79 | 1.22 | 0.37 | 0.43 | 1.16 |
| 4             | 3:2:3:5:1:0.5 | 0.59 | 0.68 | 1.15 | 0.21 | 0.25 | 1.16 |

αHexane-ethyl acetate–methanol–acetonitrile–water.
102.43 (C-8), 101.67 (C-11), 101.13 (–O–CH2–O–), 69.03 (C-2),
46.94 (C-3), 32.74 (C-9), 7.49 (CH3-8), 7.00 (CH3-6).

Compound 4: 1H-NMR (CDCl3, 400 MHz): δ 4.12 (1H, dd, J = 8, 12 Hz, H-2), 4.29 (1H, dd, J = 4, 12 Hz, H-2), 2.77–2.83 (1H, m, H-3), 12.38 (1H, s, 5-OH), 5.41 (1H, s, 7-OH),
2.66 (1H, m, H-9), 3.18 (1H, dd, J = 4, 12 Hz, H-9), 7.15
(2H, d, J = 8 Hz, H-2’, H-6’), 6.86 (2H, d, J = 8 Hz, H-3’,H-5’), 3.80 (3H, s, 4’-OCH3), 2.03 (3H, s, 6-CH3), 2.07 (3H, s,
8-CH3); 13C-NMR (CDCl3, 400 MHz): δ 198.64 (C-4),
160.40 (C-5), 159.75 (C-10), 157.91 (C-7), 130.21 (C-1’),
130.26 (C-2’, C-6’), 114.24 (C-3’, C-5’), 102.95 (C-6’),
102.43 (C-8), 101.67 (C-11), 69.05 (C-2), 55.44 (4’-OCH3),
46.99 (C-3), 32.13 (C-9), 7.49 (CH3-8), 7.00 (CH3-6).

Compared with the NMR data given in previous literature
studies, the results of compounds 1–2 were consistent with
those of components I and II in the work of Kaneda et al.
[38]; compounds 3–4 can be identified as methyllophiopogonanone A (3) and methyllophiopogonanone B (4) [39]. For
convenience, compounds 1 and 2 were named 6-aldehydo-
isophiopogonanone A (1) and 6-aldehydo-isophiopogonanone
B (2), according to the chemical structures and previous re-
ports [4–6, 38–40]. In previous studies, the two analogues
could be achieved through SGCC with benzene as the devel-
opring reagent [38, 40] or slow flow LH-20 with ethanol as
the elute solvent [39, 40], which is not suitable for large scale
purification.

3.5. Online HSCCC–DPPH Antioxidant Activity. A
schematic diagram of the instrumentation is given in Figure 5.
The homoisoflavonoid analogues of methyllophiopogonanone
A (3) and methyllophiopogonanone B (4) obtained from sub-
fraction 8 (50 mg) in ethyl acetate extract of FROJ were first
isolated by HSCCC using HEAMW (3:2:3.5:1:0.5, v/v) for (A) and HEAMW (3:2:2.5:1:1.5, v/v) for (B)

Figure 3. The recycling HSCCC chromatograms of different fractions from the fibrous roots of O. japonicus: (A) sub-fraction 7 from ethyl acetate fraction by SGCC and (B) sub-fraction 8 from ethyl acetate fraction by SGCC. Peaks: 1 = 6-aldehydo-isophiopogonanone A; 2 = 6-aldehydo-isophiopogonanone B; 3 = methyllophiopogonanone A; 4 = methyllophiopogonanone B. HSCCC conditions: revolution = 900 rpm; flow rate = 2 mL/min; temperature = 25 °C; detection wavelength = 285 nm; upper phase for stationary phase and lower phase for mobile phase; solvent sys-
tem: HEAMW (3:2:3.5:1:0.5, v/v) for (A) and HEAMW (3:2:2.5:1:1.5, v/v) for (B)
DPPH radical scavenging effect of the two compounds were also confirmed, though they had relatively ordinary activity with IC\textsubscript{50} > 1000 μg/mL.

4. Conclusion

The herbaceous plant of *O. japonicus* is well known as a functional food and traditional medicine in China and other
East Asian countries. Previous studies indicated that homoisoflavonoids are main active ingredients, and the FROJ can be the important resource of the plant. In this study, SGCC and rHSCCC was successfully developed to isolate the two pairs of homoisoflavonoid analogues from the FROJ. By the developed method, the fibrous roots could be used to obtain 4 homoisoflavonoids with satisfactory purities, which may then be used for bioactive research or quality control of crude drug or herbal preparations. It is expected to provide meaningful reference for separation and purification of analogues. Furthermore, the online HSCCC-antioxidant activity assay introduced in our experiment will be a useful technique to screening and preparative isolation of antioxidant components from medical plants.
