Abstract

Various species of Trypanosoma parasites are known to infect several wild and domestic animals worldwide. A 7-year-old Holstein cow from Baneh, Kurdistan province, was examined by a private veterinarian due to anorexia and depression. Physical examination revealed fever, enlarged subcapsular lymph node, and pale mucosa. Blood samples were taken for hematological, parasitological, and PCR examination. The large Trypanosoma spp. was microscopically observed in a stained blood smear. Decreased red blood cells (RBCs) count, packed cell volume and hemoglobin concentration were observed through complete blood cell count. Nucleated RBCs were also found in this case. Species-specific PCR assay confirmed T. theileri infection. Treatment was performed subcutaneously with diminazene aceturate. The clinical signs were improved after two days. Two-month follow-up showed no recurrence. In conclusion, T. theileri is characterized by anemia and pyrexia in a cow. To our knowledge, the present case report describes the first molecular evidence of T. theileri in Kurdistan, West of Iran.

Introduction

Trypanosoma theileri is assigned to the subgenus Megatrypanum by a classification originally based on its morphology. This species is one of the largest mammalian blood trypanosomes. The large trypomastigote form T. theileri can be revealed in peripheral blood having a long pointed posterior end with kinetoplast typically situated near the nucleus.¹ ² The main form of transmission is probably through blood-sucking arthropods such as Tabanus.³ Although T. theileri is mostly associated with mild or no pathogenicity, evidence of regenerative anemia, fever, and progressive weight loss has been revealed in sporadic clinical cases in domestic animals of several countries such as Spain, Ireland, Germany, and Italy.⁴–¹⁰ The present case report describes a cow infected with T. theileri in Kurdistan, West of Iran.

Case Description

A 7-year-old Holstein cow from Baneh county (35° 59’ 51” N 45° 53’ 07” E), located at about 249 km north of Sanandaj (Kurdistan province) in the West of Iran, was examined by a private veterinarian due to fever, anorexia, and depression. Enlarged subcapsular lymph nodes, strong heart sounds, and pale mucosa were also recorded. The blood samples from the jugular vein were collected in EDTA-containing blood collection tubes (Kendall Co., Mansfield, USA) for hematological and molecular examinations. First, Giemsa-stained blood smears were prepared for precise detection of the parasite under a light microscope (Olympus SZ61; Olympus Corporation, Tokyo, Japan) using morphological features and taxonomical key of Kaufmann.¹¹ Then, a part of the blood sample was assigned to routine hematological parameters including red blood cell (RBC) count, packed cell volume (PCV) value and hemoglobin concentration by automated hematology analyzer (Exigo, Stockholm, Sweden).

The DNA from the blood sample was extracted using a DNA extraction kit (MBST, Tehran, Iran). A pair of primers, forward 5’-CGTCTCTGCGGCCGCTAAAC-3’ and reverse 5’-TAAAGCTTCCACGGTCTTGTATGATCAGTA-3’ was used to amplify a 289 bp fragment of cathepsin L-like protein (CATL) gene from T. theileri according to the

method described by Yokoyama et al.\textsuperscript{12} Polymerase chain reaction (PCR) was carried out in 50.00 µL total reaction volume containing 5.00 µL of 10x PCR buffer, 2.00 mM MgCl\textsubscript{2} (Cinnagen, Tehran, Iran), 250 µM of each of the four deoxynucleotide triphosphates, 1.25 U Taq DNA polymerase (Fermentas Life Science, St. Leon-Rot, Germany), 50.00 pmol of each primer and 50.00 ng of extracted DNA. Amplification of parasite DNA was done in a thermocycler (CP2-003; Corbett Research, Sydney, Australia). Cycling condition for \textit{T. theileri} was 95.00 °C for 5 min, followed by 45 cycles at 95.00 °C for 30 sec, 55.00 °C for 60 sec and 72.00 °C for 10 min. The PCR products extracted from the agarose gel were sent for sequencing (SinaClon, Tehran, Iran). The \textit{T. theileri} positive control was confirmed by GenBank under the accession number of MK393794. The negative control contained all essential components of the amplification reaction except the template. The study was approved by the Ethics Committee of Faculty of Veterinary Medicine, Urmia University, Urmia, Iran (AECVU-190-2019).

## Results

Light microscopic examination of Giemsa-stained peripheral blood films revealed the presence of \textit{Trypanosoma} spp. trypomastigotes (85.00 ± 5.00 µm in length) freely scattered between erythrocytes having kinetoplast typically situated near the nucleus (Fig. 1). The PCR analysis showed an expected 289 bp fragment of the CATL gene of \textit{T. theileri} amplified from a blood sample (Fig. 2). Negative control reactions of each PCR run did not yield amplification products. The PCR product was purified, sequenced, and registered under the accession number of MK393794 in GenBank. The sequences of the CATL gene of \textit{T. theileri} obtained in the present study were compared with other CATL sequences retrieved from GenBank. Sequence analysis demonstrated the highest homology of 98.00-100% between obtained sequences and registered sequence of \textit{T. theileri} in GenBank.

Hematological examinations indicated low PCV (18.00%; reference interval: 24.00 - 46.00%), RBC count (3.55 × 10\textsuperscript{6} µL\textsuperscript{-1}; reference interval: 5.00-10.00 × 10\textsuperscript{6} µL\textsuperscript{-1}) and hemoglobin (6.10 g dL\textsuperscript{-1}; reference interval: 8.00 - 15.00 g dL\textsuperscript{-1}).\textsuperscript{13} In addition, nucleated RBCs (four per 100 white blood cells) were found in this case.

## Discussion

Microscopic examinations such as Giemsa-stained blood smears and cultivation of blood samples are mostly used as a confirmatory diagnosis of vertebrate host suffering from \textit{Trypanosoma} infections. Based on microscopic examinations, there are two reports of \textit{T. theileri} infection in cattle of Iran.\textsuperscript{14,15} However, this study was focused on molecular confirmation of \textit{T. theileri}, which is the lesser-studied species. The PCR has been proven to be more sensitive than a blood examination regarding trypanosome genomic DNA detection in the animal or vector host. Also, this method is sensitive enough to detect even one trypanosome genomic DNA per mL of blood. Also, DNA-based diagnostic methods have generally facilitated epidemiological studies of trypanosomes.\textsuperscript{12}

Prevalence of \textit{T. theileri} varies considerably in different countries ranging from 10.00 to 90.00%.\textsuperscript{7} In the previous study in Iran, a culture of blood was used and the prevalence of \textit{T. theileri} was determined as 26.47%.\textsuperscript{14} Infection of a cow by \textit{T. theileri} has been reported previously in cattle of Urmia, Iran using the cytologic examination.\textsuperscript{15} However, to the best of the authors’ knowledge, the present report is the first molecular-confirmed case of \textit{T. theileri} infection in cattle of Iran.

\textit{Trypanosoma theileri} is commonly associated with mild or no clinical signs and it is thought to have very low pathogenicity.\textsuperscript{8} In this case report, pyrexia, enlarged lymph

nodes, and decreased RBCs, PCV, and hemoglobin concentration are in agreement with clinical and hematomatological findings reported in other studies.\textsuperscript{5,9,15} Enlargement of the lymph node in infected cow could be due to extravascular localization of trypomastigotes in the lymph node.\textsuperscript{16}

In summation, the findings recorded here demonstrated that \textit{T. theileri} should be considered in the differential diagnosis of diseases characterized by anemia and pyrexia. The PCR evaluation for \textit{T. theileri} DNA should be included in the investigation of such cases to enable the rapid definitive detection of this infection, which may be more common than the previous estimation. Besides, diminazene aceturate might be effective in the treatment of \textit{T. theileri} in cattle, however; conducting further case studies are necessary to recommend successful treatment. Our findings also indicate that \textit{T. theileri} should be considered as an occasional pathogen of cattle in Iran.
