Abstract: The design and performance analysis of a 10 kW three-phase DC–DC LCL-type resonant converter having a built-in boost function were carried out. This high-power converter is proposed for its application in grid-interfacing a linear generator (LG)-based wave-energy system. Fixed-frequency control is used, and the converter was designed to operate with a lagging power factor. It is shown that all switches turn on with zero-voltage switching (ZVS) for wide input voltage and load variations. This results in reduced switching losses and stresses, which is very important in large-power applications. The performance of the converter was studied through PSIM simulation software. Theoretical and simulation results are presented for comparison. Power-loss break-down analysis of the designed converter was carried out and the summary of results is presented.

Keywords: LCL-resonant converter; DC–DC; integrated boost; dual three-phase bridge; fixed frequency; ZVS; large power

1. Introduction

Large renewable power plants are supplementing conventional power generation to face the looming energy crisis. Power from ocean waves is a huge source of renewable power that remains mostly untapped [1–4]. Wave-energy converters (WEC) are required to convert the motion of waves into electricity. Technology is slowly advancing to determine a robust WEC device [5–7]. The following wave-energy conversion technologies are reported in the literature: (i) attenuator, (ii) oscillating water column, (iii) overtopping, and (iv) point absorber. Among these technologies, one of the point-absorber type of devices, called Archimedes wave swing (AWS), is currently the most attractive device [8–10]. AWS uses a direct-drive linear generator (LG) to convert its reciprocating motion into electricity [11–15]. The structure and typical waveform of the output voltage of an LG is shown in Figure 1. This electricity cannot be used since it is a variable low frequency, wide-varying low voltage, and non-sinusoidal AC power. Hence, a suitable power electronic interface is essential to make this power usable and facilitate grid interfacing of the wave-energy source [16–18]. For grid interfacing, the variable-voltage and variable-frequency output power from LG has to be conditioned to match the grid characteristics. In grid interfacing, the LG output is first converted into DC using a front-end diode rectifier. A two stage DC–DC converter is used to change the magnitude of input DC voltage and provide galvanic isolation using a High-Frequency (HF) transformer. In the DC–DC converter, the input DC is first converted into an HF AC using an HF-switched inverter. This AC is fed to the primary of the HF transformer to change its voltage level, in addition to providing isolation. The secondary-side voltage is converted back into the DC using an output rectifier. This DC is finally converted into the
line-frequency AC of magnitude equal to the grid voltage. The block diagram of grid integration of a wave-energy plant is shown in Figure 2. The power rating of linear generators used in wave-energy generation is typically of the order of tens to hundreds of kWs [2–4]. To realize DC systems in such high-power applications, DC–DC converters are very important, especially when HF transformer isolation and different voltage levels are required [19]. Different types of direct-drive takeoff systems used in harnessing wave energy using linear generators are described in References [20–23].

DC–DC converters used for this type of application (true with most alternate-energy sources) have to operate with a very wide change (e.g., 2:1) in input voltage while requiring output-voltage step-up (boost) characteristics. With the HF transformer isolation and soft-switching, the efficiency of the DC–DC converters can be increased in addition to reducing the size and cost of the power-conditioning unit with overall improved performance. Therefore, DC–DC resonant converters are proposed for this application. Some converter topologies available in the literature for large-power generation applications are: A 10 kW dual three-phase bridge DC–DC converter was designed, and its simulation results are given in Reference [24]. Design, analysis, and experimental results of a 600 W dual-bridge DC–DC converter are presented in Reference [25], and it is proposed for still higher power ratings. In Reference [26], a comparison of 100 kW DC–DC soft-switching converter topologies is presented. In Reference [27], the performance of a high power-density 50 kW DC–DC converter with single-phase dual-active bridge topology is presented. The performance of an LCL-type DC–DC series resonant-converter topology with experimental results of a 300 W prototype is presented in Reference [28]. A 1 kW series-parallel DC–DC resonant converter with an input-boosting feature is described and the experimental results are presented in Reference [29]. The detailed design procedure of a dual half-bridge LCL-type series resonant converter with integrated boost function is given and simulation results of a 2.4 kW rating converter are presented in Reference [30]. Steady-state analysis of a ZVS PWM converter and its small-signal analysis is described, and the experimental results of a 2 kW prototype are presented in Reference [31]. The experimental results of a 1 MW dual-active bridge DC–DC converter are presented, and its performance and control are validated in Reference [32]. The design and PSIM simulation study of the performance of a 10 kW three-phase DC–DC LCL-type series resonant converter with integrated boost function are presented in Reference [33] for steady-state operating conditions. In Reference [34], it is shown that conduction loss and switching losses are reduced for an isolated bidirectional dual-active-bridge series-resonant DC–DC converter operating at

Figure 1. (a) Structure of a permanent-magnet linear generator, (b) typical waveform of phase voltage of a linear-generator output (v_phase).

Figure 2. Block diagram of grid integration of a wave-energy plant [24].
high frequency. The results are validated with a 1 kW prototype of the converter. An isolated high-gain DC–DC converter for PV applications is proposed, and its performance is studied through simulations and also by building a prototype of 3 kW power rating in Reference [35]. The steady-state analysis and performance study of a three-phase DC–DC converter, and the simulation and experimental results of a 900 W converter prototype, are presented in Reference [36]. The converter topology proposed in References [24,25] has several advantages over the other topologies. Some of these advantages are reduced stress on components and filter size with fixed-frequency operation, a wide ZVS range for wide variations in input voltage, and at least 50% of load can be supplied in the case of a fault on one of the modules. Hence, this topology has been chosen to design the converter for medium-to-large power-generation applications. The work presented in this paper is an extension of the author’s PhD thesis [24]. A performance study of the designed converter under step changes in load through PSIM simulations is the major contribution. The outline of this paper is as follows: In Section 2, the circuit details of the designed converter are briefly presented. In Section 3, the design summary of the converter, including the selection of voltage and power rating, is presented. In Section 4, the performance of the converter for variations in input voltage and load under a steady state and for step changes in the load is studied through PSIM simulations, and the results are presented. Conclusions are drawn in Section 5.

2. Circuit Details of the Designed Converter

The circuit diagram of the converter designed in this paper for large-power applications as proposed in References [24,25] is shown in Figure 3. This converter consists of two three-phase inverter bridges, each having six metal-oxide-semiconductor-field-effect-transistors (MOSFETs) with antiparallel diodes and a lossless snubber capacitor across it. The output terminals of these inverters are connected to a three-phase diode rectifier through a three-phase resonant circuit consisting of inductance $L_s$ and capacitance $C_s$ in each phase and a three-phase HF transformer ($T_1, T_2$) of $1:n_t$ turns ratio. These modules are supplied with $V_{bus}$ and are connected in parallel so that they equally share the load power. Between the same output phases of the two inverter bridges, the primary windings of a three-phase HF-boost transformer ($T_3$) of $n_b:1$ turns ratio are connected. The output of the boost transformer is given to a three-phase diode boost-rectifier bridge. The boost-rectifier bridge output voltage is filtered by $L_f$ and $C_f$. This filtered output voltage ($V_{boost}$) is connected in series with the input DC source to realize power supply $V_{bus}$ (i.e., $V_{bus} = V_{in} + V_{boost}$), applied across three-phase inverter bridge Modules 1 and 2. The secondary windings of the three-phase boost transformer are shown in Wye connection (they can also be connected in Δ). The gating signals for the three-phase inverter-bridge switches are 180° wide [24,25]. Six gating signals are required for each three-phase bridge, and these gating signals are applied in order, with a delay of 60° to obtain balanced three-phase inverter output voltage. Each switch conducts for 180°, and three switches remain on at any point of time in a given interval (e.g., $S_1 S_2 S_3, S_2 S_3 S_4, S_3 S_4 S_5, S_4 S_5 S_6, S_5 S_6 S_1, S_6 S_1 S_2$). There are six intervals of operation in each cycle, and the duration of each interval is 60°. Fixed-frequency control is obtained by phase shifting the gating signals of Module 2 with respect to Module 1 by an angle $\delta$, which creates potential difference across the primary windings of the HF-boost transformer. At minimum input voltage ($V_{in,min}$) and full load, the gating signals of Module 2 are shifted by 180° to generate a square-wave voltage waveform of pulse width $\delta = \pi$ in each phase across the primary windings of the three-phase boost transformer. The phase shift is varied to change the pulse-width $d$ of quasisquare wave generated across the primary windings of boost transformer $T_3$ to regulate the load voltage for variations in input voltage and load.
The criterion for choosing a procedure, as given in References [24, 28], was followed in designing the fixed-frequency controlled ZVS-integrated boost dual three-phase bridge DC–DC LCL-type series resonant converter for linear generator-based large-wave-power generation applications. In this section, the selection of voltage and power ratings is first discussed, and then design summary is presented.

3.1. Selection of Voltage and Power Ratings

A number of LGs used in wave power with different specifications are found in the literature [1–11]. The power and input voltage ratings are chosen as per the LG ratings given in References [2,33]. In Table 1, the specimen specifications of an LG, as given in Reference [2], are presented. For illustration purposes, a grid voltage of 240 V (L–L) and 60 Hz is considered. Based on this grid voltage, the output-voltage rating of the designed converter was obtained as 400 V. The criterion for choosing $V_{\text{bus}}$ is $V_{\text{bus}}(\text{min}) > V_{\text{in}}(\text{max})$, and $V_{\text{bus}}(\text{max})$ is decided based on the available higher voltage ratings of the switching devices. This idea of a design with a higher $V_{\text{bus}}$ value reduces the switch currents and voltage ratings of the HF transformer, and the tank circuit elements. Based on this criterion, $V_{\text{bus}} = 600$ V was chosen [25]. This DC bus voltage was applied across the three-phase HF inverter bridges.

Table 1. Linear-generator specifications [2,33].

| Parameter                              | Value                      |
|----------------------------------------|----------------------------|
| Rated power at 0.7 m/s                 | 10 kW                      |
| Open circuit voltage (Line) at 0.7 m/s | 200 V                      |
| Generator resistance                   | 0.44 Ω                     |
| Generator inductance                   | 11.7 mH                    |
| Iron losses at 0.7 m/s                 | 0.57 kW                    |
| Length of air gap                      | 3 mm                       |
| Size of magnet block                   | 6.5 × 35 × 100 mm³         |
| Pole width                             | 50 mm                      |
| Stator sides (number)                  | 4                          |
| Stator length (vertical)               | 1.264 m                    |
| Translator length (vertical)           | 1.867 m                    |
| Weight of translator                   | 1000 kg                    |

3.2. Design Summary

The converter was designed by following the procedure outlined in References [24,28], and the key design equations, together with various parameter notations, are summarized in Appendix A. The specifications of the designed converter are given in Table 2. Using the design curves presented in Reference [25], the design parameters are optimized. The selected parameters are \( Q = 4 \), \( F = 1.1 \), and \( L_s/L_p = 0.1 \). For the chosen design parameters, converter gain \( M = V_o/V_{bus} \) was calculated by using Equation (A15) as \( M = 0.6286 \) p.u. Output voltage, when reflected on primary side of the HF transformer, is \( V'_o = V_o/n_t = 371.2 \) V. Therefore, the HF main transformer \((T_1 \text{ and } T_2)\) turns the ratio of \( n_t = V_o/V'_o = 1.078 \). Load resistance \( R_L = V_o^2/(P_o/2) = 32 \) Ω (since each module equally shares the load, power output is taken as \( P_o/2 = 5 \) kW). The load resistance referred to on the primary side, \( R_L' = R_L/n_t^2 = 27.54 \) Ω. The values of tank circuit elements \( L_s \) and \( C_s \) are determined by solving Equation (A16) as, \( L_s = 192.97 \) µH and \( C_s = 15.88 \) nF. Since \( L_s/L_p = 0.1 \), \( L_p = 1.93 \) mH on the primary side. Therefore, \( L_p' = n_t^2L_p = 2.24 \) mH is connected on the secondary side in each phase. This includes the magnetizing inductance of the HF transformer. Total impedance using Equations (A17)–(A22) is \( Z_{AN} = 16.75 + j21.27 \) Ω, \( |Z_{AN}| = 27.08 \) Ω, \( \varphi = 51.78^\circ \). The maximum current in the tank circuit elements \( L_s \) and \( C_s \) using Equation (A23) is \( I_{Lsp} = 14.11 \) A. The maximum value of voltage across \( C_s \) using Equation (A25), \( V_{Csp} = 1.41 \) kV. The maximum value of the current through STAR-connected parallel inductors \( L_p' \) on the secondary side is \( I_{Lp,p} = 163 \) mA. If the parallel inductors are connected in \( \Delta \), then the peak value of current through the \( \Delta \)-connected inductors \( L_{ab}, L_{bc}, L_{ca} \) (secondary side) is \( I_{Lab,p} = 94.11 \) mA. The initial tank current using Equation (A24) is \( I_{Lao} = -11.09 \) A. The negative sign of \( I_{Lao} \) indicates that the tank circuit is operating in lagging pf mode. The per-phase inductance required in the primary windings of the three-phase boost transformer calculated using Equation (A14) is \( 2.75 \) µH. The \( L_f \) and \( C_f \) filter components of the three-phase boost rectifier, determined using Equations (A12)–(A13), are \( L_f = 5.0 \) µH and \( C_f = 20.0 \) µF. The device ratings, calculated using Equations (A1)–(A10), are: MOSFET: \( I_{sw}(\text{rms}) = 22.91 \) A, \( I_{sw}(\text{av}) = 13.17 \) A, \( V_{DS}(\text{max}) = 600 \) V and, \( I_{DM}(\text{av}) = 0.84 \) A. Boost rectifier diodes: \( I_{Db}(\text{av}) = 24.69 \) A, \( V_{Db}(\text{max}) = 465 \) V. Output rectifier diodes: \( I_{Do}(\text{av}) = 4.17 \) A, \( V_{Do}(\text{max}) = 400 \) V. For the chosen value of \( V_{bus} = 600 \) V, IXYS-VMM90-09F (900 V, 85A, \( R_{DS} = 76 \) mΩ, \( t_f = 140 \) ns) MOSFET was selected so that HF operation was possible and converter specifications were met. A snubber capacitance of \( C_n = 4.64 \) nF was found for the chosen MOSFET, with a switch turn-off current \( i_o = 39.78 \) A using Equation (A11). A series/parallel combination of selected MOSFETs or insulated-gate-bipolar-transistors (IGBTs) would further increase the power ratings which is essential in wave energy generation applications.
Table 2. Specifications of the designed converter [33].

| Parameter                      | Value          |
|--------------------------------|----------------|
| Input voltage ($V_{in}$)       | 135 V to 270 V |
| Output voltage ($V_o$)         | 400 V          |
| Output Power ($P_o$)           | 10 kW          |
| DC bus voltage ($V_{bus}$)     | 600 V          |
| Switching frequency ($f_s$)    | 100 kHz        |

4. Simulation Results

4.1. Steady-State Conditions

The steady-state performance of the converter outlined in Section 3 was verified by using PSIM simulations. The following five cases were considered to validate theoretical results [24]. Case 1: $V_{in}$(min) = 135 V, full load; Case 2: $V_{in}$(max) = 270 V, full load; Case 3: $V_{in}$(min) = 135 V, half load; Case 4: $V_{in}$(max) = 270 V, half load; Case 5: $V_{in}$(min) = 135 V, 20% of full load. Sample waveforms from PSIM simulations for Cases 1, 2, and 5 are presented in Figures 4–15. In simulations, three-phase transformers were obtained by using three single-phase transformers. Leakage and magnetizing inductances were obtained by recalculating the per-unit values of the measured values of the three-phase boost transformer in from Reference [25] (rated at 618 W) built in the laboratory. These values are: total leakage inductance of 3.0 $\mu$H (referred to primary side) and magnetizing inductance of 170 $\mu$H (referred to primary side). The estimated leakage inductance of the boost transformer $L_{bl}$ @ 3.0 $\mu$H was slightly greater than the calculated value of the per-phase inductance required in the primary windings of the three-phase boost transformer ($L_{bt}$ = 2.75 $\mu$H). Hence, no additional inductance was necessary. Thus, leakage inductance was profitably utilized to achieve ZVS. To compensate for the voltage drop due to leakage inductance (i.e., voltage drop due to commutation overlap), the turns ratio of the boost transformer was made 2.428:1 instead of 2.5806:1. For the three-phase main transformers, three ideal single-phase transformers were used as the leakage inductances were absorbed in the resonant inductances. In the simulations, the Y-connected parallel inductor $L_p'$, on the secondary side of three-phase main transformers $T_1$ and $T_2$ of Figure 2, was connected in $\Delta$ by taking their equivalent values (i.e., $L_{ab} = L_{bc} = L_{ca} = 3L_{p}'$). For MOSFET, an $R_{DS} = 76$ m$\Omega$ was used. Snubber capacitors used include the MOSFET drain to source capacitances. All remaining components were chosen as ideal. Since this resonant power converter operates in soft-switching, the effect of electromagnetic interference (EMI) was minimized. Wiring inductance at the output of inverter is used profitably as part of resonant circuit. However, to minimize the EMI and effect of other parasitic elements (due to wiring and coupling, etc.) that might still occur, techniques used in Reference [37] could be used while designing the printed circuit boards. The effect of any other parasitic elements can be minimized by using a careful design of the printed circuit board. The impact of the geometrical parameters of the PCB structure on the electromagnetic coupling is analyzed in Reference [37]. In simulations, each three-phase inverter bridge module was given with three-phase 180$^\circ$ wide normal gating signals. To regulate output voltage, the gating signals of Module 2 were phase-shifted from those of Module 1 to give a pulse width of $\delta$. Since the calculated value of $\delta$ was very close to the value of $\delta$ to be set in the simulations, very few iterations were used in the simulations to determine the required value of $\delta$ to obtain the rated output voltage. This is an advantage as it reduces simulation time. It was observed from the simulation results [24] that all the switches, in both Module 1 and 2 of the converter, operate with ZVS for all input-voltage variation from $V_{in}$(min) to $V_{in}$(max), and for load variation from full load to 20% of full load, e.g., Figures 6, 10, and 14. The maximum resonant current (phase) declined from approximately (i) Module 1: 13.81 A at $V_{in}$(max) = 270 V, full load (Figure 8a) to 2.77 A at $V_{in}$(min) = 135 V, 20% of full load (Figure 12a); (ii) Module 2: 13.86 A at $V_{in}$(max) = 270 V, full load (Figure 8b) to 2.83 A at $V_{in}$(min) = 135 V, 20% of full load (Figure 12b). For Module 1: peak switch current with $V_{in}$(min) = 135 V approximately decreased from 49.51 A at full load (Figure 6a) to 13.66 A
at 20% of full load (Figure 14a). For Module 2: peak switch current with \( V_{in}(\text{min}) = 135 \text{ V} \) decreased approximately from 49.45 A at full load (Figure 6b) to 12.13 A at 20% of full load (Figure 14b). It is worth noting that the peak values of the switch/resonant currents reduce as load current is reduced.

The summary of power-loss breakdown analysis of the converter is presented in Table 3. A bar chart of the efficiency percentage obtained from calculations and simulations is shown in Figure 16. Comparison of the results obtained from calculations and simulations is presented in Table 4. It is to be noted that, comparing the results presented in Table 4 and in Figure 16, \( R_{DS} = 76 \text{ m}\Omega \) was chosen in the simulation for MOSFETs, and all other elements were ideal. Hence, efficiency values from simulations are higher than those from calculations.

![Figure 4](image)

**Figure 4.** PSIM simulation waveforms for Case 1: \( V_{in}(\text{min}) = 135 \text{ V}, \text{ full load}, R_L = 16 \Omega, \delta = 180^\circ. \ v_{AB}, v_{BC}, v_{CA}, \text{ and } i_{LsA}, i_{LsB}, i_{LsC} \) for (a) Module 1 and (b) Module 2. \( v_{\text{rect,in}_{ab}}, v_{\text{out}_{ab}}, \text{ and } v_{CsA} \) for (c) Module 1 and (d) Module 2.

4.2. **Performance Under Step Changes in Load**

A converter is robust when it maintains output voltage as constant even when the load suddenly changes. This ability of the converter is tested by simulating its performance in PSIM software for sudden variations in load. The change in load from full load to half load, and then to 20% of full load (also in reverse order), was created by operating a load control switch. The phase-shifted gating signals with appropriate phase-shift angle \( \delta \), as given in Table 4, for corresponding step changes in load were applied to the MOSFETs of Module 2. Some important sample waveforms, obtained through simulations for step changes in load current from full load to half load at \( t = 0.2 \text{ seconds} \), and half load to 20% of full load at \( t = 0.25 \text{ seconds} \) (step change is made after steady-state operation), are presented in Figure 17. The robustness of the converter is rigorously tested by creating two step changes i.e., from 20% of full load to half load at \( t = 0.2 \text{ seconds} \), and from half load to full load at \( t = 0.25 \text{ seconds} \). as indicated in Figure 18. It is observed from Figures 17 and 18 that there is smooth transition of output voltage during load step change while maintaining constant output voltage at the full-load value. From Figure 19, it can be seen that the resonant tank current remains sinusoidal throughout loading conditions. The variations of resonant tank currents while the load is changed from light load to higher loads are shown in Figure 20. It is observed in Figure 21 that the current through the switches did not spike up during sudden changes in loading conditions. It can also be observed from Figure 21 that all
switches in both modules remained in ZVS, i.e., the antiparallel diodes conduct before the respective switches conduct. This can be ensured by observing negative switch currents, as shown in Figure 21.

**Figure 5.** PSIM simulation waveforms for Case 1: \(V_{\text{in}}(\min) = 135\) V, full load, \(R_L = 16\) Ω, \(\delta = 180\degree\). \(i_{\text{lab}}, i_{\text{lsA}},\) and \(i_{\text{rect,in,a}}\) for (a) Module 1 and (b) Module 2. \(v_{L\text{lab}}, v_{L\text{bc}}, v_{L\text{ca}},\) and \(i_{\text{rect,in,a}}\) for (c) Module 1 and (d) Module 2.

For $t = 0.2$ s, expanded waveform of $V_o$ for full load ($R_L = 16 \Omega$, $\delta = 180^\circ$) to half load ($R_L = 32 \Omega$, $\delta = 107^\circ$) at $t = 0.2$ sec.; (a) waveforms of $v_o$ and $i_o$, (b) expanded waveform of $v_o$, for full load ($R_L = 16 \Omega$, $\delta = 180^\circ$); (c) waveforms of $v_o$ and $i_o$, (d) expanded waveform of $v_o$, for half load ($R_L = 32 \Omega$, $\delta = 107^\circ$) to 20% of full load ($R_L = 80 \Omega$, $\delta = 98^\circ$) at $t = 0.25$ sec. Output voltage $v_o$ to be regulated is 392 V.
Figure 18. Simulation waveforms with $V_{in}(\text{min}) = 135$ V for step changes in $i_o$ from 20% of full load ($R_L = 80 \, \Omega, \delta = 98^\circ$) to half load ($R_L = 32 \, \Omega, \delta = 107^\circ$) at $t = 0.2 \, \text{s}$, and then to full load ($R_L = 16 \, \Omega, \delta = 180^\circ$) at $t = 0.25 \, \text{s}$: (a) waveforms of $v_o$ and $i_o$, (b) expanded waveform of $v_o$.

Figure 19. Simulation waveforms with $V_{in}(\text{min}) = 135$ V for step changes in load current at $t = 0.2 \, \text{s}$: (a) waveforms of resonant tank currents ($i_{Lsa}$, $i_{Lsb}$, $i_{Lsc}$) in Phases A, B, and C, (b) expanded waveforms of $i_{Lsa}$, $i_{Lsb}$, $i_{Lsc}$ for full load ($R_L = 16 \, \Omega, \delta = 180^\circ$) to half load ($R_L = 32 \, \Omega, \delta = 107^\circ$) for Module 1, (c) $i_{Lsa}$, $i_{Lsb}$, $i_{Lsc}$, (d) expanded waveforms of $i_{Lsa}$, $i_{Lsb}$, $i_{Lsc}$ for half load ($R_L = 32 \, \Omega, \delta = 107^\circ$) to 20% of full load ($R_L = 80 \, \Omega, \delta = 98^\circ$) for Module 2.
Theoretical and simulation results were compared and they agreed very closely. The designed converter has been verified by using PSIM simulations for variations in input voltage and the load. A low-power (600 W) prototype of the proposed converter with different input/output voltages was built in the laboratory and reported in Reference [38], the proposed converter could be designed for still-higher power ratings, with reduced switching frequency. The series and parallel combinations of such three-phase cells can also be used to realize much higher power ratings. A low-power (600 W) prototype of the proposed converter maintained ZVS for all switches and for wide variations in supply voltage and load. This converter has been verified by using PSIM simulations for variations in input voltage and the load.

5. Conclusions

A fixed-frequency-controlled integrated-boost dual three-phase bridge DC–DC LCL-type SRC, of 135 to 270 V input, 10 kW, and 400 V output was designed. The performance of the designed converter has been verified by using PSIM simulations for variations in input voltage and the load. Power-loss breakdown analysis of the converter was carried out and the summary is presented. Theoretical and simulation results were compared and they agreed very closely. The designed converter was investigated and the summary is presented.
converter maintained ZVS for all switches and for wide variations in supply voltage and load. This resulted in higher efficiency by minimizing turn-on losses. This feature is very useful in alternate-energy applications generating large amounts of power. Due to the advent of SiC power MOSFETS, e.g., Reference [38], the proposed converter could be designed for still-higher power ratings, with high switching frequency, as new MOSFETS of higher voltage ratings (>1000 V) and higher current ratings (>100 A) are now available. IGBTs are also considered for higher power, but at the cost of reduced switching frequency. The series and parallel combinations of such three-phase cells can also be used to realize much higher power ratings. A low-power (600 W) prototype of the proposed converter with different input/output voltages was built in the laboratory and reported in Reference [25]. As future work, an experimental 10 kW converter, based on the given specifications, will be built in the power-electronics laboratory, and results will be verified with the theoretical and simulation results obtained in this paper. The effect of various parasitic elements was also included in the simulation.

Conflicts of Interest: The authors declare no conflict of interest.

Appendix A. Design Equations (A24) and (A25)

The phasor circuit used in the analysis of the Figure 3 converter is shown in Figure A1. Some of the important equations used in the converter design are given below:

\[
\begin{align*}
I_{\text{SW(rms)}} &= \sqrt{\frac{1}{\pi} \left\{ I_b^2 + \frac{I_{\text{DS(max)}}^2}{2} \left( \sin \Phi + \frac{\sin(2 \Phi)}{2} \right) + 2 I_{Lsp} I_b \cos \Phi \cos \left( \frac{\pi}{3} - \Phi \right) \right\}} \\
I_{\text{SW(ave)}} &= \frac{1}{2\pi} \left\{ I_b \left( \frac{\pi}{3} \right) + I_{Lsp} \cos \Phi + \cos \left( \frac{\pi}{3} - \Phi \right) \right\} \\
I_{\text{DM(ave)}} &= \frac{I_{Lsp}}{2\pi} \left( \cos \Phi - \cos \left( \frac{\pi}{3} - \Phi \right) \right) \\
v_{\text{DS(max)}} &= V_{\text{bus(max)}}
\end{align*}
\]

Appendix: Design Equations (24) and (25)
The phasor circuit used in the analysis of the Figure 3 converter is shown in Figure A1. Some of the important equations used in the converter design are given below:

\[
\begin{align*}
I_{\text{SW(rms)}} &= \sqrt{\frac{1}{\pi} \left\{ I_b^2 + \frac{I_{\text{DS(max)}}^2}{2} \left( \sin \Phi + \frac{\sin(2 \Phi)}{2} \right) + 2 I_{Lsp} I_b \cos \Phi \cos \left( \frac{\pi}{3} - \Phi \right) \right\}} \\
I_{\text{SW(ave)}} &= \frac{1}{2\pi} \left\{ I_b \left( \frac{\pi}{3} \right) + I_{Lsp} \cos \Phi + \cos \left( \frac{\pi}{3} - \Phi \right) \right\} \\
I_{\text{DM(ave)}} &= \frac{I_{Lsp}}{2\pi} \left( \cos \Phi - \cos \left( \frac{\pi}{3} - \Phi \right) \right) \\
v_{\text{DS(max)}} &= V_{\text{bus(max)}}
\end{align*}
\]
Average current through each diode of the boost rectifier is

\[ I_{Db} = I_{Lf}(av)/3 \]  

(A5)

Average current through inductive filter used at the output of boost rectifier is

\[ I_{Lf}(av) = (I_{Lfmin} + I_{Lfmax})/2 \]  

(A6)

Maximum voltage across each of the boost rectifier diodes is

\[ V_{Db}(max) = 2V_{bus}/n_b \]  

(A7)

Average current through each diode of the output rectifier is

\[ I_{Do}(ave) = I_{RL}(av)/(3 \times 2) \]  

(A8)

Average current through the load resistance is

\[ I_{RL}(av) = P_o/V_o \]  

(A9)

Maximum voltage across each diode of the output rectifier is

\[ V_{Do}(max) = V_o \]  

(A10)

Snubber capacitance used across each switch is

\[ C_n = i_o t_f / (2V_{bus,max}) \]  

(A11)

Filter inductance used at the output of the boost rectifier is

\[ L_f = V_{Lf(6fs)}/(12f_s \pi I_{Lf(6fs)}) \]  

(A12)

Filter capacitance used at the output of the boost rectifier is

\[ C_f = I_{Cf(6fs)}/(12f_s \pi V_{Cf(6fs)}) \]  

(A13)

Energy stored in inductance connected in series with each phase of the primary windings of the ideal three-phase boost transformer is

\[ E_{Lbt} = \frac{1}{2} L_b t_b^2 > \frac{1}{2} (2C_n V_{bus}^2) \]  

(A14)

Converter gain is

\[ M = \frac{1}{\left[\left\{1 + (L_s/L_p)(1 - (1/F^2))\right\}^2 + \left\{(\pi^2/6)Q(F - (1/F))\right\}^2\right]^{1/2}} \]  

(A15)

where

\[ Q = \omega_t L_s/R'_t; \quad F = \omega_s/\omega_r = f_s/f_r; \quad \omega_s = 2\pi f_s; \quad \omega_r = 2\pi f_r = \frac{1}{\sqrt{L_s C_s}} \]  

(A16)

The parameters of the phasor equivalent circuit shown in Figure A1 are

\[ Z_{AN} = R_{AN} + jX_{AN} \]  

(A17)
\[|Z_{AN}| = \left[R_{AN}^2 + X_{AN}^2\right]^{1/2}\]  
(A18)

\[\Phi = tan^{-1}\left(\frac{X_{AN}}{R_{AN}}\right)\]  
(A19)

where,

\[R_{AN} = \left(\frac{R_{ac}X_{2Lp}}{R_{ac}^2 + X_{2Lp}^2}\right)\]  
(A20)

\[X_{AN} = \left[(X_{Ls} + X_{Cs}) + \left(\frac{R_{ac}^2 X_{Lp}}{R_{ac}^2 + X_{2Lp}^2}\right)\right]\]  
(A21)

\[X_{Ls} = \omega_s L_s; \quad X_{Lp} = \omega_s L_p; \quad X_{Cs} = -1/\omega_s C_s\]  
(A22)

\[I_{Lsp} = \frac{V_{AN1}(\text{peak})}{|Z_{AN}|}\]  
(A23)

Initial switch current is

\[i_{Ls0} = I_{Lsp} \sin(-\Phi)\]  
(A24)

Peak resonant capacitor voltage is

\[V_{Csp} = I_{Lsp}|X_{Cs}|\]  
(A25)
