Abstract

We describe various strengthenings of the concept of topological transitivity. Especially when one departs from the family of invertible systems, a number of interesting properties arise. We present the architecture of implications among ten reasonable notions of transitivity.
1 Introduction

For us a dynamical system \((X, f)\) is a pair with \(X\) a compact metric space, \(f : X \to X\) a continuous map and the dynamics given by iteration. While we don’t explicitly assume it, our main interest is in systems \((X, f)\) with \(f\) not invertible.

For subsets \(A, B \subset X\) we define the hitting time set

\[
N(A, B) = \{ n \in \mathbb{N} : f^n(A) \cap B \neq \emptyset \} = \{ n \in \mathbb{N} : A \cap f^{-n}(B) \neq \emptyset \},
\]

where \(\mathbb{N}\) is the set of positive integers. We identify a singleton with its unique element, writing \(N(x, B)\), for example, for \(N(\{x\}, B)\). We call the system topologically transitive when for every open (= open and nonempty) set \(U \cup \bigcup_{n=1}^{\infty} f^n(U)\) is dense in \(X\), or, equivalently if for every open pair \(U, V \subset X\), the set of hitting times \(N(U, V)\) is nonempty. A point \(x \in X\) is called a transitive point when for every open \(V \subset X\), the hitting time set \(N(x, V)\) is non-empty. This is equivalent to saying that the orbit \(O(x) = \{ f^n(x) : n \in \mathbb{N} \}\) is dense in \(X\). We denote by \(\text{Trans}(f)\) the set of transitive points. Transitivity is equivalent to a kind of indecomposability of the phase space with respect to the acting group.

There are a number of slightly different versions of topological transitivity, which are surveyed in [3]. The one we have chosen implies, by compactness, that \(f\) is surjective. Furthermore, either \(X\) is finite, and so consists of a single periodic orbit, or it is perfect, i.e. it has no isolated points. Our definition serves to exclude compactifications of the translation map on \(\mathbb{N}\) or on \(\mathbb{Z}\) the set of integers. On a perfect space all of the definitions agree.

Here we study some stronger forms of transitivity

1. Topological Transitivity (TT).
2. Strong Transitivity (ST).
3. Very Strong Transitivity (VST).
4. Minimality (M).
5. Weak Mixing (WM).

6. Exact Transitivity (ET).

7. Strong Exact Transitivity (SET).

8. Strong Product Transitivity (SPT).

9. Mixing, or Topological Mixing (TM).

10. Locally Eventually Onto (LEO).

These concepts are not new to literature. Parry [16] had defined “Strongly transitive systems” which we here call “very strongly transitive systems”. The concept of “strongly transitive” that we define here has been studied as property “(B)” by Nagar and Kannan [13] and by Akin, Auslander and Nagar [2]. The concept of “Locally eventually onto” was introduced by Denker and Urbanskii in [8] where they called such systems “exact”. We follow Kaminski et al. [10] who use the label “exactness” for a somewhat different property, and then use “locally eventually onto” for the earlier notion.

It is known that the properties of strongly transitive, very strongly transitive and locally eventually onto are observed in the dynamics of piece-wise monotonic maps, subshifts of finite type, $\beta$-shifts, and Julia sets.

If we consider the induced dynamics on $2^X$, the space of non-empty closed subsets of $X$ given the Hausdorff topology, then it has been shown in Akin, Auslander and Nagar [2] that for the induced system the concepts “strongly transitive”, and “local eventually onto” are equivalent (and so these are equivalent to very strongly transitive, strongly product transitive and strong exact transitive as well). Furthermore, these occur exactly when the original system $(X, f)$ is locally eventually onto.

Our purpose here is to define these concepts and list various equivalent conditions and properties. In the process we will show that the following implications hold

\[
\begin{align*}
LEO & \implies ET, \quad TM \implies WM \implies TT; \\
LEO & \implies SPT \implies SET \implies ET, ST \implies TT; \\
LEO, M & \implies VST \implies ST \implies TT.
\end{align*}
\]

(1.1)

We will show also that the properties are distinct by showing that various reverse implications fail.
The reader may note the absence of any discussion of sensitive dependence on initial conditions, i.e. sensitivity. Any topologically transitive system \((X, f)\) which admits an equicontinuity point is almost equicontinuous and uniformly rigid and so \(f\) is a homeomorphism, see [1] and [9]. Hence, the topologically transitive, noninvertible systems which are our primary concern are all sensitive.

Acknowledgement: A part of this work was done when A. Nagar visited University of Maryland and she gratefully acknowledges the hospitality of the Mathematics Department at College Park.

2 Transitivity Properties

For a dynamical system \((X, f)\) and a point \(x \in X\) the orbit of \(x\) is \(\mathcal{O}(x) = \{f^n(x) : n \in \mathbb{N}\}\), regarded either as a sequence in, or as a subset of, the state space \(X\). Notice that \(x = f^0(x)\) need not be an element of \(\mathcal{O}(x)\). We let \(\omega(x)\) be the set of limit points of the orbit so that
\[
\omega(x) = \bigcap_{N \in \mathbb{N}} \{f^n(x) : n \geq N\}, \quad \text{and} \quad \mathcal{O}(x) \cup \omega(x) = \overline{\mathcal{O}(x)},
\]
the orbit closure of \(x\).

A point \(x\) is called recurrent when \(x \in \omega(x)\).

We denote by
\[
\mathcal{O}^-(x) = \bigcup_{n \in \mathbb{N}} \{f^{-n}(x)\} = \{y \in X : f^n(y) = x \text{ for some } n \in \mathbb{N}\},
\]
and call it the negative orbit of \(x\). We also define the partial orbit sets. For \(N \in \mathbb{N}\)
\[
\mathcal{O}_N(x) = \{f^n(x) : 1 \leq n \leq N\}, \quad \text{and} \quad \mathcal{O}^-_N(x) = \bigcup_{1 \leq n \leq N} \{f^{-n}(x)\}.
\]

A subset \(A \subset X\) is called + invariant if \(f(A) \subset A\) (or, equivalently, if \(A \subset f^{-1}(A)\)), − invariant if \(f^{-1}(A) \subset A\) and invariant if \(f(A) = A\). For example, \(\mathcal{O}(x)\) is + invariant, \(\mathcal{O}^-(x)\) is − invariant. Clearly, \(A\) is + invariant iff \(x \in A\) implies \(\mathcal{O}(x) \subset A\) and \(A\) is − invariant iff \(x \in A\) implies \(\mathcal{O}^-(x) \subset A\).
For every $x \in X$ the set of limit points $\omega(x)$ is invariant. Notice that $y \in \omega(x)$ if and only if it is the limit of a subsequence of the orbit sequence $\{f^n(x) : n \in \mathbb{N}\}$. It easily follows that

$$f(\omega(x)) = \omega(x) = \omega(f(x)).$$  \hfill (2.1)

Clearly, a set is $+$ invariant if and only if its complement is $-$ invariant. We call a set $A \subset X$ to be weakly $-$ invariant if $A \subset f(A)$ or, equivalently, if for all $x \in A$ there exists $x_1 \in A$ such that $f(x_1) = x$. Thus, $A$ is weakly $-$ invariant if and only if $f(A \cap f^{-1}(A)) = A$.

**Lemma 2.1** Let $A \subset X$.

(a) If $A$ is $-$ invariant and $f$ is surjective, then $A$ is weakly $-$ invariant.

(b) $A$ is invariant, i.e. $A = f(A)$, if and only if $A$ is both $+$ invariant and weakly $-$ invariant. $A = f^{-1}(A)$ if and only if $A$ is both $+$ invariant and $-$ invariant and, in that case, it is invariant.

(c) If $A$ is either $+$ invariant, weakly $-$ invariant or invariant then the closure $\overline{A}$ satisfies the corresponding property.

(d) Assume $A$ is closed and nonempty. If $A$ is either $+$ invariant or weakly $-$ invariant then $A$ contains a closed, nonempty invariant set. If $A$ is $-$ invariant then it contains a closed, nonempty subset which is $-$ invariant and invariant.

(e) Assume $f$ is an open map. If $A$ is $+$ invariant then the interior $A^\circ$ is $+$ invariant. If $A$ is $-$ invariant then $\overline{A}$ is $-$ invariant.

**Proof:** (a) If $x \in A \subset f(X)$ then there exists $x_1 \in X$ such that $f(x_1) = x$. Because $A$ is $-$ invariant, $x_1 \in A$.

(b) These are obvious from the definitions since $f$ is surjective.

(c) By compactness, $f(\overline{A}) = \overline{f(A)}$. The results follow from the monotonicity of the closure operator.

(d) If $A$ is $+$ invariant, let $A_0 = A$ and $A_n = f^n(A)$ for $n \in \mathbb{N}$. This is a decreasing sequence of nonempty closed sets with $f(A_n) = A_{n+1}$. Let $B = \cap_n A_n$, a nonempty closed set by compactness. For all $n$ $f(B) \subset f(A_n) = A_{n+1}$. So $B$ is $+$ invariant. If $x \in B$ then $x \in A_{n+1}$ implies $f^{-1}(x) \cap A_n \neq \emptyset$. Hence, $\cap_n f^{-1}(x) \cap A_n = f^{-1}(x) \cap B$ is nonempty by compactness again. Hence, $B$ is $-$ invariant and so is invariant by (b).

If $A$ is weakly $-$ invariant, let $A_0 = A$ and, inductively, let $A_n = A_{n-1} \cap f^{-1}(A_{n-1})$. This is a decreasing sequence of nonempty closed sets with $f(A_n) = A_{n-1}$. Let $B = \cap_n A_n$ and proceed as before.
If \( A \) is \(-\) invariant, let \( A_0 = A \) and, inductively, \( A_n = f^{-1}(A_{n-1}) \). Again, this is a decreasing sequence of nonempty closed sets with \( f(A_n) = A_{n-1} \). Let \( B = \bigcap_n A_n \) as before and observe that \( f^{-1}(B) = \bigcap_n f^{-1}(A_n) = \bigcap_n A_{n+1} = B \).

(e) If \( f \) is open then \( f(A^o) \) is an open subset of \( f(A) \). If also \( A \) is \(+\) invariant then

\[
    f(A^o) \subset f(A)^o \subset A^o.
\]

The \(-\) invariance result follows by taking complements.

\( \square \)

**Remark:** (a) The constructions in part (d) yield the maximum invariant subset in each case.

(b) The closure of a \(-\) invariant set need not, in general, be \(-\) invariant. Let \( X = \{0\} \cup \{\frac{1}{n} : n \in \mathbb{N}\} \). Define \( f \) on \( X \) by \( 0, 1 \mapsto 0 \) and \( \frac{1}{n} \mapsto \frac{1}{n+1} \) for \( n \in \mathbb{N} \). The set \( A = \{\frac{1}{n+1} : n \in \mathbb{N}\} \) is \(-\) invariant but its closure is not.

A subset \( A \subset X \) is called \( \epsilon \) dense if it meets every open \( \epsilon \) ball in \( X \).

**Lemma 2.2** Let \( \{A_n\} \) be a sequence of subsets of \( X \).

(a) \( \bigcup_{n=1}^{\infty} A_n \) is dense if and only if for every \( \epsilon > 0 \) there exists \( N \in \mathbb{N} \) such that \( \bigcup_{n=1}^{N} A_n \) is \( \epsilon \) dense.

(b) If each \( A_n \) is open and \( \bigcup_{n=1}^{\infty} A_n = X \) then there exists \( N \in \mathbb{N} \) such that \( \bigcup_{n=1}^{N} A_n = X \).

**Proof:** (a) Because \( X \) is compact it has a finite cover by \( \epsilon/2 \) balls. A set which meets each of these is \( \epsilon \) dense.

(b) This follows from compactness.

\( \square \)

**Definition 2.3** A system \( (X, f) \) is called exact if for every pair of open \( \epsilon \) subsets \( U, V \subset X \) there exists \( n \in \mathbb{N} \) such that \( f^n(U) \cap f^n(V) \neq \emptyset \).

We call the system fully exact if for every pair of open \( \epsilon \) subsets \( U, V \subset X \) there exists \( n \in \mathbb{N} \) such that \( (f^n(U) \cap f^n(V))^o \neq \emptyset \).

The definition of exactness follows [10]. Thus, \( (X, f) \) is exact (or fully exact) if and only if for every pair of open \( \epsilon \) subsets \( U, V \subset X \) we have \( \bigcup_n (f^n(U) \cap f^n(V)) \neq \emptyset \) (resp. \( \bigcup_n (f^n(U) \cap f^n(V))^o \neq \emptyset \)).
Clearly, if $f$ is an open map then exactness and fully exactness are equivalent.

**Theorem 2.4** (a) If $(X, f)$ is exact and $f$ is injective then $X$ is a singleton, i.e. the system is trivial.

(b) $(X, f)$ is fully exact if and only if for every pair of open subsets $U, V \subset X$ we have $(\bigcup_n f^n(U) \cap f^n(V))^\circ \neq \emptyset$.

**Proof:** (a) : If $X$ is not a singleton then it contains a pair of disjoint open subsets $U, V$. Since $f^n(U) \cap f^n(V) \neq \emptyset$ for some $n$, the map $f$ is not injective.

(b) : If the system is fully exact then

\[
\bigcup_n (f^n(U) \cap f^n(V))^\circ \subset (\bigcup_n f^n(U) \cap f^n(V))^\circ
\]

implies that the latter set is nonempty.

Let $A \subset U, B \subset V$ be closed sets with nonempty interior. If the open set $G = (\bigcup_n f^n(A) \cap f^n(B))^\circ$ is nonempty then it is a Baire space with a countable, relatively closed cover $\{G \cap f^n(A) \cap f^n(B) : n \in \mathbb{N}\}$. So by the Baire Category Theorem some $f^n(A) \cap f^n(B)$ has nonempty interior in $G$ and so in $X$. In fact, $\bigcup_n (f^n(A) \cap f^n(B))^\circ$ is dense in $G$. It follows that $(X, f)$ is fully exact.

\[\Box\]

We note that these two notions are different and in general far away from the property of transitivity.

**Example 2.5** There exist systems which are exact but not fully exact and which are fully exact and surjective but not topologically transitive.

Consider the system $([-1, 1], f)$ with

\[
f(x) = \begin{cases} 
-(2 + 2x), & -1 \leq x \leq -1/2; \\
2x, & -1/2 \leq x \leq 1/2; \\
2 - 2x, & 1/2 \leq x \leq 1.
\end{cases}
\]

Then any interval contained in $[-1, 0]$ or $[0, 1]$ eventually covers $[-1, 0]$ or $[0, 1]$ respectively with intersection $\{0\}$. This system is exact but not fully exact.
Whereas consider the system \([-1, 1], g\) with
\[
g(x) = \begin{cases} 
-(2 + 2x), & -1 \leq x \leq -1/2; \\
2x, & -1/2 \leq x \leq 1/2; \\
3 - 4x, & 1/2 \leq x \leq 1.
\end{cases}
\]

Then any interval contained in \([-1, 0]\) or \([0, 1]\) eventually covers \([-1, 0]\) or \([-1, 1]\) respectively with intersection \([-1, 0]\). This system is fully exact.

The reader can refer to Theorem 2.7 below to see that these systems are not transitive.

\[\square\]

**Definition 2.6** 
\((X, f)\) is called:

1. **Topologically Transitive (TT)** if for every open \(U \subset X\), \(\bigcup_{n=1}^{\infty} f^n(U)\) is dense in \(X\).
2. **Strongly Transitive (ST)** if for every open \(U \subset X\), \(\bigcup_{n=1}^{\infty} f^n(U) = X\).
3. **Very Strongly Transitive (VST)** if for every open \(U \subset X\) there is a \(N \in \mathbb{N}\) such that \(\bigcup_{n=1}^{N} f^n(U) = X\).
4. **Minimal (M)** if there is no proper, nonempty, closed invariant subset of \(X\).
5. **Weak Mixing (WM)** if the product system \((X \times X, f \times f)\) is topologically transitive.
6. **Exact Transitive (ET)** if for every pair of open sets \(U, V \subset X\),
\[\bigcup_{n=1}^{\infty} (f^n(U) \cap f^n(V))\) is dense in \(X\).
7. **Strongly Exact Transitive (SET)** if for every pair of open sets \(U, V \subset X\),
\[\bigcup_{n=1}^{\infty} (f^n(U) \cap f^n(V)) = X\).
8. **Strongly Product Transitive (SPT)** if for every positive integer \(k\) the product system \((X^k, f^{(k)})\) is strongly transitive.
9. Mixing or Topologically Mixing (TM) if for every pair of open sets $U, V \subset X$, there exists an $N \in \mathbb{N}$ such that $f^n(U) \cap V \neq \emptyset$ for all $n \geq N$.

10. Locally Eventually Onto (LEO) if for every open set $U \subset X$, there exists $N \in \mathbb{N}$ such that $f^N(U) = X$, and so $f^n(U) = X$ for all $n \geq N$.

In the case of the property SPT, we rejected the obvious label *Strongly Weak Mixing*.

We now provide equivalent descriptions of these properties.

For topological transitivity there are many equivalences in the literature, see e. g. [3, 13, 11, 18].

**Theorem 2.7** For a dynamical system $(X, f)$ the following are equivalent.

1. The system is topologically transitive.
2. For every pair of open sets $U$ and $V$ in $X$, there exists $n \in \mathbb{N}$ such that $f^{-n}(U) \cap V \neq \emptyset$.
3. For every pair of open sets $U, V \subset X$ the set $N(U, V)$ is nonempty.
4. For every pair of open sets $U, V \subset X$ the set $N(U, V)$ is infinite.
5. There exists $x \in X$ such that the orbit $\mathcal{O}(x)$ is dense in $X$, i.e. the set $\text{Trans}(f)$ of transitive points is nonempty.
6. The set $\text{Trans}(f)$ of transitive points equals \{ $x : \omega(x) = X$ \} and it is a dense, $G_δ$ subset of $X$.
7. For every open set $U \subset X$, \( \bigcup_{n=1}^\infty f^n(U) \) is dense in $X$.
8. For every open set $U \subset X$, and $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that \( \bigcup_{n=1}^N f^n(U) \) is $\epsilon$ dense in $X$.
9. For every open set $U \subset X$, \( \bigcup_{n=1}^\infty f^{-n}(U) \) is dense in $X$. 

(10) For every open set \( U \subset X \), and \( \epsilon > 0 \), there exists \( N \in \mathbb{N} \) such that 
\[
\bigcup_{n=1}^{N} f^{-n}(U) \text{ is } \epsilon \text{ dense in } X.
\]

(11) If \( U \subset X \) is open and \( - \)-invariant, then \( U \) is dense in \( X \).

(12) If \( E \subset X \) is closed and \( + \)-invariant, then \( E = X \) or \( E \) is nowhere dense in \( X \).

If \( (X, f) \) is topologically transitive, then \( f \) is surjective and either \( X \) is a single periodic orbit or it is a perfect space, i.e. has no isolated points.

**Proof:** Notice that condition (7) is the definition of TT and so, of course, (1) \( \iff \) (7). Condition (7) clearly implies that \( f(X) \) is dense and so equals \( X \) by compactness, i.e. \( f \) is surjective.

We first show that if \( \text{Trans}(f) \neq \emptyset \) then either \( X \) is a periodic orbit or it is perfect. Furthermore, \( x \in \text{Trans}(f) \) implies \( \omega(x) = X \).

Assume \( \mathcal{O}(x) \) is dense. If \( x \in \mathcal{O}(x) \) then \( x \) is a periodic point with finite orbit \( \mathcal{O}(x) \) dense in \( X \) and equals \( \omega(x) \). That is, \( X \) is a periodic orbit. If \( x \not\in \mathcal{O}(x) \) then the dense set \( \mathcal{O}(x) \) is not closed and so is infinite. Thus, the points of the orbit are all distinct. This implies that if \( y \in X \setminus \mathcal{O}(x) \) then it is the limit of some sequence \( f^{n_i}(x) \) with \( n_i \in \mathbb{N} \) and \( n_i \to \infty \). In particular, there is such a sequence with \( f^{n_i}(x) \to x \) and so \( f^{n_i+k}(x) \to f^k(x) \) for all \( k \in \mathbb{N} \). Thus, no point of \( X \) is isolated and every point is contained in \( \omega(x) \).

Each of (2), (7), (9) \( \iff \) (3) is an easy exercise. (9) \( \iff \) (11) since \( \bigcup_{n=1}^{\infty} f^{-n}(U) \)
is \( - \)-invariant and equals \( U \) if \( U \) is \( - \)-invariant. (7) \( \iff \) (8) and (9) \( \iff \) (10) from Lemma 2.2 (a). (11) \( \iff \) (12) by taking complements.

This leaves (4), (5) and (6).

(6) \( \Rightarrow \) (5), and (4) \( \Rightarrow \) (3) are obvious.

(9) \( \Rightarrow \) (6):

It is clear that 
\[
\text{Trans}(f) = \bigcap_{U} \bigcup_{n=1}^{\infty} f^{-n}(U),
\]

with \( U \) varying over a countable base. By assumption (9) each \( \bigcup_{n=1}^{\infty} f^{-n}(U) \) is a dense open set. The Baire Category Theorem then implies that \( \text{Trans}(f) \) is a dense \( G_\delta \) set. By our initial argument, \( \text{Trans}(f) = \{ x : \omega(x) = X \} \).
(5) ⇒ (4): (4) is obvious if $X$ is a periodic orbit. Otherwise, (5) and our initial argument imply that $X$ is perfect. If $O(x)$ is dense then it meets every opene set in an infinite set because $X$ is perfect. It then follows that $N(U,V)$ is infinite for every opene pair $U,V$.

\[ \blacksquare \]

**Remark:** Clearly, (12) implies that if $(X,f)$ is topologically transitive then $X$ is not the union of two proper, closed, +invariant subsets. If $X$ is perfect then the converse is true as well, see [3].

**Corollary 2.8** For a system $(X,f)$ the set $\text{Trans}(f)$ is invariant and – invariant.

Every transitive point is recurrent.

**Proof:** Since $\text{Trans}(f) = \{ x : \omega(x) = X \}$ by (6), and $\omega(x) = \omega(f(x))$ by 2.1 it follows that the set of transitive points is invariant and – invariant. In particular, $x \in \omega(x)$ says that every transitive point is recurrent.

\[ \blacksquare \]

**Proposition 2.9** Let $(X,f)$ be a topologically transitive system with $X$ infinite. For any $x \in X$ and $n \in \mathbb{N}$ $f^{-n}(x)$ is nowhere dense and so $O^-(x)$ is of first category.

**Proof:** Suppose $U \subset f^{-n}(x)$ is opene. There exists $y \in U \cap \text{Trans}(f)$. Since $\text{Trans}(f)$ is invariant, $x \in \text{Trans}(f)$. Hence, $f^k(x) \in U$ for some $k \in \mathbb{N}$. This implies that $f^{k+n}(x) = x$ and so $x$ is a periodic point which is also a transitive point. It follows that $X$ consists exactly of the orbit of $x$ and so it is finite. Contrapositively, if $X$ is infinite then the closed set $f^{-n}(x)$ is nowhere dense for all $n \in \mathbb{N}$. As the countable union of nowhere dense sets, $O^-(x)$ is of first category.

\[ \blacksquare \]

Recall our identification of a singleton with the point it contains. In particular,

$$N(U,x) = \{ n \in \mathbb{N} : x \in f^n(U) \} = \{ n \in \mathbb{N} : f^{-n}(x) \cap U \neq \emptyset \}.$$
Theorem 2.10  For a dynamical system $(X, f)$ the following are equivalent.

(1) The system is strongly transitive.

(2) For every open set $U \subset X$ and every point $x \in X$, there exists $n \in \mathbb{N}$ such that $x \in f^n(U)$.

(3) For every open set $U \subset X$ and every point $x \in X$, the set $N(U, x)$ is nonempty.

(4) For every open set $U \subset X$ and every point $x \in X$, the set $N(U, x)$ is infinite.

(5) For every $x \in X$, the negative orbit $O^-(x)$ is dense in $X$.

(6) For every $x \in X$, and $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that $O_{\epsilon}^-(x)$ is $\epsilon$ dense in $X$.

(7) If $E \subset X$ is nonempty and $-$ invariant, then $E$ is dense in $X$.

If $(X, f)$ is strongly transitive, then $f$ is topologically transitive.

Proof: That each of (1), (3) and (5) $\iff$ (2) are easy exercises. (5) $\iff$ (6) by Lemma 2.2 (a).

(4) $\Rightarrow$ (3): Obvious.

(5) $\Rightarrow$ (4): If $n \in N(U, x)$ then there exists $y \in U$ with $f^n(y) = x$. Because $O^-(y)$ is dense there exists $k \in N(U, y)$. That is, there exists $z \in U$ such that $f^k(z) = y$ and so $f^{k+n}(z) = x$. Hence, $k + n \in N(U, x)$. Thus, the set $N(U, x)$ is unbounded.

(5) $\iff$ (7): $O^-(x)$ is $-$ invariant and if $x \in E$ and $E$ is $-$ invariant then $O^-(x) \subset E$.

Condition (3) implies condition (3) of Theorem 2.7. Hence, strongly transitive implies topological transitive.

Recall that a subset $L \subset \mathbb{N}$ is syndetic if there exists $N \in \mathbb{N}$ such that every interval of length $N$ in $\mathbb{N}$ meets $L$.

Theorem 2.11  For a dynamical system $(X, f)$ the following are equivalent.

(1) The system is very strongly transitive.
(2) For all \( \epsilon > 0 \), there exists \( N \in \mathbb{N} \) such that \( \mathcal{O}_N(x) \) is \( \epsilon \) dense in \( X \) for every \( x \in X \).

If \((X,f)\) is very strongly transitive then for every open set \( U \subset X \) and every point \( x \in X \), the set \( N(U,x) \) is syndetic.

**Proof:** (1) \( \Rightarrow \) (2): Cover \( X \) by \( \epsilon/2 \) balls \( V_1, \ldots, V_m \). There exists an \( N \in \mathbb{N} \) large enough that \( \bigcup_{n=1}^{N} f^n(V_i) = X \), for \( i = 1, \ldots, m \). Fix an \( x \in X \), then for any \( y \in X \), \( y \in V_i \) for some \( i \) and \( x \in f^n(V_i) \) for some \( n \) with \( 1 \leq n \leq N \). Therefore \( \mathcal{O}_N(x) \) is \( \epsilon \) dense.

(2) \( \Rightarrow \) (1): Suppose that \( N \in \mathbb{N} \) is such that \( \mathcal{O}_N(x) \) is \( \epsilon \) dense for every \( x \in X \). Let \( W \) be an \( \epsilon \) ball in \( X \). For \( x \in X \) there exists \( x' \in W \) with \( f^n(x') = x \) where \( 1 \leq n \leq N \). Hence, \( x \in \bigcup_{n=1}^{N} f^n(W) \). Since \( x \) is arbitrary, \( \bigcup_{n=1}^{N} f^n(W) = X \).

If \( X = \bigcup_{n=1}^{N} f^n(U) \) then for every \( k \in \mathbb{N} \), \( X = f^k(X) = \bigcup_{n=k+1}^{N+k} f^n(U) \). Thus, for every \( x \in X \), the set \( N(U,x) \) meets every interval of length \( N \) in \( \mathbb{N} \).

\( \square \)

**Corollary 2.12** If \((X,f)\) is very strongly transitive then for any open \( U, V \subset X \), the set \( N(U,V) \) is syndetic.

**Proof:** If \( x \in V \), then \( N(U,x) \subset N(U,V) \).

\( \square \)

**Theorem 2.13** If \( f \) is an open map then the following are equivalent.

(1) The system is very strongly transitive.

(2) The system is strongly transitive.

(3) \( X \) does not contain a proper, closed – invariant subset.

**Proof:** (1) \( \Rightarrow \) (2) \( \Rightarrow \) (3) whether the map is open or not.

(2) \( \Rightarrow \) (1): If \( U \) is open then each \( f^n(U) \) is open and so if \( \{ f^n(U) : n \in \mathbb{N} \} \) covers \( X \) then it has a finite subcover.

(3) \( \Rightarrow \) (2): If \( E \) is a nonempty – invariant subset of \( X \) then by Lemma \[2.11\] (e) \( \overline{E} \) is a nonempty, closed – invariant subset and so it equals \( X \). Thus, \( E \) is dense. This verifies condition (6) of Theorem \[2.10\].
Theorem 2.14  For a dynamical system $(X, f)$ the following are equivalent.

(1) The system is minimal.

(2) For every open set $U \subset X$ and every point $x \in X$, there exists $n \in \mathbb{N}$ such that $f^n(x) \in U$.

(3) For every open set $U \subset X$ and every point $x \in X$, the set $N(x, U)$ is nonempty.

(4) For every open set $U \subset X$ and every point $x \in X$, the set $N(x, U)$ is syndetic.

(5) For every $x \in X$, the orbit $\mathcal{O}(x)$ is dense in $X$.

(6) The set $\text{Trans}(f)$ is equal to the entire space $X$.

(7) For every $x \in X$, $\omega_f(x) = X$.

(8) For every open set $U \subset X$, $\bigcup_{n=1}^{\infty} f^{-n}(U) = X$.

(9) For every open set $U \subset X$, there exists $N \in \mathbb{N}$ such that $\bigcup_{n=1}^{N} f^{-n}(U) = X$.

(10) If $E \subset X$ is nonempty, closed and invariant, then $E = X$.

(11) If $E \subset X$ is nonempty, closed and $+$ invariant, then $E = X$.

(12) If $E \subset X$ is nonempty, closed and weakly $-$ invariant, then $E = X$.

If $(X, f)$ is minimal, then it is very strongly transitive.

Proof: Notice that condition (8) is the definition of minimality and so, of course, (1) $\iff$ (8).

Again each of the equivalences (2), (3) and (8) $\iff$ (5) is an easy exercise. 

(5) $\iff$ (6) is obvious and (6) $\iff$ (7) by Theorem 2.7 (6).

(8) $\iff$ (9) by compactness.

(4) $\Rightarrow$ (3) : Obvious.
If \( X = \bigcup_{n=1}^{N} f^{-n}(U) \) then for every \( k \in \mathbb{N} \), \( X = f^{-k}(X) = \bigcup_{n=k+1}^{N+k} f^{-n}(U) \). Thus, for every \( x \in X \), the set \( N(x, U) \) meets every interval of length \( N \) in \( \mathbb{N} \).

(5) \( \Leftrightarrow \) (11): \( O(x) \) is closed and + invariant and if \( x \in E \) with \( E \) + invariant then \( O(x) \subset E \).

(10) \( \Rightarrow \) (11) and (12): If \( E \) is nonempty, closed and either + invariant or weakly \(-\) invariant then by Lemma 2.1 (d) \( E \) contains a nonempty, closed invariant subset.

If \( (X, f) \) is minimal and \( U \) is open then by (9) there exists \( N \in \mathbb{N} \) such that \( \bigcup_{n=1}^{N} f^{-n}(U) = X \). Since \( Trans(f) = X \) the system is topologically transitive and so by Theorem 2.7 \( f \) is surjective. Apply \( f^{N+1} \) to get that \( \bigcup_{n=1}^{N} f^{-n}(U) = X \). That is, \( f \) is very strongly transitive.

\[ \square \]

**Theorem 2.15** If \( f \) is a homeomorphism, \( (X, f) \) is strongly transitive if and only if it is very strongly transitive if and only if it is minimal.

**Proof:** A homeomorphism is open and so strongly transitive \( \Leftrightarrow \) very strongly transitive by Theorem 2.13. In any case, minimality \( \Rightarrow \) very strongly transitive by Theorem 2.14. For a homeomorphism we can reverse the argument.

For very strongly transitive \( \Rightarrow \) minimality we see that \( \bigcup_{n=1}^{N} f^{-n}(U) = X \), apply \( f^{-N-1} \) to get \( \bigcup_{n=1}^{N} f^{-n}(U) = X \).

\[ \square \]

Let \( h : X_1 \to X_2 \) be a continuous surjection between compact spaces. \( h \) is called **irreducible** if \( A \subset X_1 \) with \( A \) closed and \( h(A) = X_2 \) implies \( A = X_1 \).

We define \( Inj_h = \{ x \in X_1 : \{ x \} = h^{-1}(h(x)) \} \).

We call \( h \) almost one-to-one when \( Inj_h \) is dense in \( X_1 \). An almost one-to-one map is clearly irreducible and if the spaces are metrizable then the converse holds. Furthermore, if \( U \subset X_1 \) is open and \( x \in U \cap Inj_h \) then \( h(U) \) is a neighborhood of \( h(x) \). For details, see, for example, [4] Lemma 1.1.

We recover a result from [12]

**Corollary 2.16** If \( (X, f) \) is minimal then \( f : X \to X \) is an almost one-to-one map. In particular, \( (X, f) \) is not fully exact unless it is trivial.
Proof: Since the system is minimal, $f$ is surjective. It suffices to show that $f$ is irreducible.

If $A \subset X$ is closed and $f(A) = X$ then $A \subset f(A)$ and so $A$ is a closed, nonempty, weakly – invariant subset. Hence, $A = X$ by (9) of Theorem 2.14.

Assume that $(X, f)$ is fully exact and nontrivial. Let $U, V$ be disjoint open sets and let $n \in \mathbb{N}$ and $W$ open such that $f^n(U) \cap f^n(V) \supset W$. Let $U_1 = U \cap f^{-n}(W)$ and $V_1 = V \cap f^{-n}(W)$. These are disjoint open sets with $f^n(U_1) = f^n(V_1)$. It follows that $(U_1 \cup V_1) \cap \text{Inj} f^n = \emptyset$. Thus, $f^n$ is not almost one-to-one and so is not irreducible. Since the composition of irreducible maps is irreducible, it follows that $f$ is not irreducible. By the above argument, $(X, f)$ is not minimal.

$\square$

Theorem 2.17 For a dynamical system $(X, f)$ the following are equivalent.

1. The system is weak mixing.

2. For triple of open sets $U, V, W$ in $X$, there exists $N \in \mathbb{N}$ such that $f^{-N}(U) \cap V \neq \emptyset$ and $f^{-N}(U) \cap W \neq \emptyset$.

3. For triple of open sets $U, V, W$ in $X$, there exists $N \in \mathbb{N}$ such that $f^N(U) \cap V \neq \emptyset$ and $f^N(U) \cap W \neq \emptyset$.

4. For every $N \in \mathbb{N}$ the product system $(X^N, f^{(N)})$ is topologically transitive.

5. For every open set $U \subset X$, and $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that $f^{-N}(U)$ is $\epsilon$ dense in $X$.

6. For every open set $U \subset X$, and $\epsilon > 0$, $f^{-N}(U)$ is $\epsilon$ dense in $X$ for infinitely many $N \in \mathbb{N}$.

7. For every open set $U \subset X$, and $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that $f^N(U)$ is $\epsilon$ dense in $X$.

8. For every open set $U \subset X$, and $\epsilon > 0$, $f^N(U)$ is $\epsilon$ dense in $X$ for infinitely many $N \in \mathbb{N}$.
Proof: That (1) ⇔ (2) and (3) are characterizations of weak mixing given by Petersen, [17]. The equivalence (1) ⇔ (4) is a well-known consequence of the Furstenberg Intersection Lemma. Both are reviewed, for example, in [2].

(5) ⇒ (2) and (7) ⇒ (3): We choose $\epsilon > 0$ small enough that both $V$ and $W$ contain $\epsilon$ balls.

(6) ⇒ (5) and (8) ⇒ (7): Obvious.

(4) ⇒ (6) and (8): Let $V_1, ..., V_k$ be a finite cover of $X$ by $\epsilon/2$ balls. Because the product system $(X^k, f^k)$ is topologically transitive, there exist infinitely many $N_1, N_2$ such that $N_1 \in N(U, V_1) \cap ... \cap N(U, V_k)$ and $N_2 \in N(V_1, U) \cap ... \cap N(V_k, U)$. These conditions imply that $f^{N_1}(U)$ and $f^{-N_2}(U)$ are $\epsilon$ dense.

\[\square\]

**Theorem 2.18** Let $(X, f)$ be a dynamical system.

(a) If $(X, f)$ is exact transitive then it is weak mixing.

(b) The following conditions are equivalent.

(1) The system is strongly exact transitive.

(2) For every pair of open sets $U, V$, $\bigcup_{n \in \mathbb{N}} (f \times f)^n(U \times V)$ contains the diagonal $\text{id}_X$.

(3) For every $x \in X$, the negative $f \times f$ orbit $O^-(x, x)$ is dense in $X \times X$.

If $(X, f)$ is strongly exact transitive then it is exact transitive and strongly transitive.

Proof: (a) Condition (2) of Theorem 2.17 clearly holds for an exact transitive system.

(b) All three conditions say that for every $x \in X$ and open $U, V \subset X$ there exists $n \in \mathbb{N}$ such that $x \in f^n(U)$ and $x \in f^n(V)$.

\[\square\]

**Theorem 2.19** (a) If $(X, f)$ is exact transitive then it is topologically transitive and exact.

(b) If $(X, f)$ is topologically transitive and fully exact then it is exact transitive.

(c) If $(X, f)$ is strongly exact transitive then it is fully exact.
Proof: (a) : Obvious.
(b) : Assume \((X, f)\) is topologically transitive and fully exact. For an opene pair \(U, V\) there exists a transitive point \(x\) in the opene set \((\bigcup_n f^n(U) \cap f^n(V))\). So there exists \(n\) so that \(x \in f^n(U) \cap f^n(V)\). The orbit \(O(x)\) is then contained in \(\bigcup_{k \geq n} f^k(U) \cap f^k(V)\) and so the latter set is dense.
(c) : This follows from Theorem 2.4 (b).

This shows that exact transitivity is a slight strengthening of the conjunction of exactness and topological transitivity.

Theorem 2.20 For a dynamical system \((X, f)\) the following are equivalent.

1. The system is strongly product transitive.
2. For \(\epsilon > 0\) and every finite subset \(F \subset X\), there exists \(N \in \mathbb{N}\) such that \(f^{-N}(x)\) is \(\epsilon\) dense in \(X\) for all \(x \in F\).
3. For \(\epsilon > 0\) and every finite subset \(F \subset X\), there exist infinitely many \(N \in \mathbb{N}\) such that \(f^{-N}(x)\) is \(\epsilon\) dense in \(X\) for all \(x \in F\).
4. The collection of subsets of \(\mathbb{N}\): \(\{N(U, x) : x \in X\text{ and } U\text{ open in } X\}\)
   has the finite intersection property (or equivalently it generates a filter of subsets of \(\mathbb{N}\)).

If \((X, f)\) is strongly product transitive then it is strong exact transitive.

Proof: (1) \(\Rightarrow\) (3): Let \(\{U_i : i = 1, ..., K_1\}\) be a finite cover of \(X\) by open \(\epsilon/2\) balls. Given a finite set \(F = \{x_j : j = 1, ..., K_2\} \subset X\). Let \(K = K_1 \cdot K_2\), and label the points of \(X^K\) by index pairs \(ij\). Define the point \(x \in X^K\) by \(x_{ij} = x_j\). Let \(U_{ij} = U_i\) and let \(U\) be the open subset of \(X^K\) which is the product of the \(U_{ij}\)’s. Because the product system \((X^K, f^{(K)})\) is strongly transitive, Theorem 2.10 (4) implies that there exist \(N\) arbitrarily large such that for each such \(N U \cap (f^{(K)})^{-N}(x) \neq \emptyset\) That is, there exists \(z \in U\) with \((f^{(K)})^N(z) = x\). So for each pair \(ij\), \(z_{ij} \in U_{ij} = U_i\) and \(f^N(z_{ij}) = x_{ij} = x_j\). Thus, \(f^{-N}(x_j) \cap U_i \neq \emptyset\) for all \(i, j\). Hence, each \(f^{-N}(x_j)\) is \(\epsilon\) dense because a set which meets every element of a cover by \(\epsilon/2\) balls is \(\epsilon\) dense.

(3) \(\Rightarrow\) (2): Obvious.

(2) \(\Rightarrow\) (4): Given \(N(U_1, x_1), ..., N(U_k, x_k)\) choose \(\epsilon > 0\) so that each \(U_i\) contains an \(\epsilon\) ball and let \(F = \{x_1, ..., x_k\}\). By (2) there exists \(N\) such that
$f^{-N}(x_i)$ is \(\epsilon\) dense for all \(i\). Thus, $f^{-N}(x_i)$ meets $U_i$ and so $N \in N(U_i, x_i)$ for all \(i\).

(4) \(\Rightarrow\) (1): Let $x = (x_1, ..., x_k) \in X^k$. Let $U$ contain $U_1 \times ... \times U_k$. Then $N(U, x) \supset N(U_1, x_1) \cap ... \cap N(U_k, x_k)$.

If the system is strongly product transitive then by Theorem 2.10 (5) applied to $(X \times X, f \times f)$, the negative orbit $O^-(x, x)$ is dense in $X \times X$. By Theorem 2.18(b)(3) it follows that $(X, f)$ is strong exact transitive.

\(\blacksquare\)

**Theorem 2.21** For a dynamical system $(X, f)$ the following are equivalent.

(1) The system is topologically mixing.

(2) For every pair of open sets $U, V \subset X$ the set $N(U, V)$ is cofinite.

(3) For every open set $U \subset X$, and $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that $f^{-n}(U)$ is $\epsilon$ dense in $X$ for all $n \geq N$.

(4) For every open set $U \subset X$, and $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that $f^n(U)$ is $\epsilon$ dense in $X$ for all $n \geq N$.

If $(X, f)$ is topologically mixing then it is weak mixing.

**Proof:** That (1) \(\iff\) (2) and (3), (4) \(\Rightarrow\) (2) are obvious.

(2) \(\Rightarrow\) (3) and (4): Let $V_1, ..., V_k$ be a finite cover of $X$ by $\epsilon/2$ balls. As the intersection of cofinite sets, $N(U, V_1) \cap ... \cap N(U, V_k)$ and $N(V_1, U) \cap ... \cap N(V_k, U)$ are cofinite.

\(\blacksquare\)

**Theorem 2.22** For a dynamical system $(X, f)$ the following are equivalent.

(1) The system is locally eventually onto.

(2) For all $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that $f^{-N}(x)$ is $\epsilon$ dense in $X$ for every $x \in X$.

(3) For all $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that $f^{-n}(x)$ is $\epsilon$ dense in $X$ for every $x \in X$ and every $n \geq N$. 

19
If \((X, f)\) is locally eventually onto then it is strongly product transitive and topologically mixing.

**Proof:** Notice that if \(f^N(U) = X\) then \(f^n(U) = X\) for all \(n \geq N\).

\((1) \Rightarrow (3):\) Let \(\{U_1, \ldots, U_m\}\) be a cover by \(\epsilon/2\) balls. There exists an \(N\) such that \(n \geq N\) implies \(f^n(U_i) = X\) for \(i = 1, \ldots, m\). Then \(f^{-n}(x)\) meets each \(U_i\) for all \(x \in X\) and \(n \geq N\). So all such \(f^{-n}(x)\) are \(\epsilon\) dense.

\((3) \Rightarrow (2):\) Obvious.

\((2) \Rightarrow (1):\) Given an open \(U\), let \(\epsilon > 0\) be such that \(U\) contains an \(\epsilon\) ball. If \(f^{-N}(x)\) is \(\epsilon\) dense for all \(x\) then \(f^{-N}(x)\) meets \(U\) for every \(x\). Thus, \(f^N(U) = X\).

\(\Box\)

**Remark:** It is clear that if \((X, f)\) is locally eventually onto then \(N(U, x)\) is co-finite in \(\mathbb{N}\) for all open \(U \subset X\) and all \(x \in X\). It is not clear that the converse holds even if \(f\) is an open map.

The various forms of transitivity that we have discussed can be best illustrated in the case of symbolic dynamics. Hence, we consider when a subshift satisfies these transitivity conditions.

For a finite set \(A\) with the discrete topology, let \(A^N\) be the space of all one sided infinite sequences provided with the product topology, and let \(\sigma\) be the shift map, defined by \(\sigma(x)_n = x_{n+1}\) for all \(n \in \mathbb{N}\).

Regarding \(A\) as an alphabet, a word, \(v\), is a finite sequence consisting of letters of \(A\), and we write \(|v|\) for the length of the word \(v\). If \(v\) is a word and \(w\) is a word or element of \(A^N\), we write \(vw \in \mathcal{V}\) for the obvious concatenation.

Let \(\Omega\) be a closed, shift invariant subset of \(A^N\). The system \((\Omega, \sigma)\) is called a subshift of \((A^N, \sigma)\). \(\Omega\) is completely determined by its “vocabulary” (language) \(\mathcal{V}\), the collection of all finite words which appear in some \(x \in \Omega\).

If \(x \in \Omega\) and \(n > 0\), \(x_{[1,n]}\) denotes the word consisting of the first \(n\) entries of \(x\).

Notice that as \(v\) varies over \(\mathcal{V}\), the cylinder sets

\([v] = \{x \in \Omega : x_{[1,|v|]} = v\}\)

comprise a basis of clopen sets for the topology on \(\Omega\).

**Theorem 2.23** Let \((\Omega, \sigma)\) be a subshift with its associated vocabulary \(\mathcal{V}\).
(a) \( (\Omega, \sigma) \) is topologically transitive if and only if for all \( v \in V \) and all \( w \in V \), there exists \( a \in V \) such that \( vaw \in V \).

(b) \( (\Omega, \sigma) \) is strongly transitive if and only if for all \( v \in V \) and all \( x \in \Omega \), there exists \( a \in V \) such that \( vax \in \Omega \).

(c) \( (\Omega, \sigma) \) is very strongly transitive if and only if whenever \( v \in V \), there is a finite collection \( V_v \subset V \) such that for every \( x \in \Omega \), \( vax \in \Omega \) for some \( a \in V_v \).

(d) \( (\Omega, \sigma) \) is minimal if and only if whenever \( v \in V \) then \( v \) occurs in \( x \) for all \( x \in \Omega \).

(e) \( (\Omega, \sigma) \) is weak mixing if and only if whenever \( v_1, v_2 \in V \) with \( |v_1| = |v_2| \), for all \( w \in V \) there exist \( a_1, a_2 \in V \) with \( |a_1| = |a_2| \) and \( v_1a_1w, v_2a_2w \in V \).

(f) \( (\Omega, \sigma) \) is exact if and only if whenever \( v_1, v_2 \in V \) with \( |v_1| = |v_2| \), there exist \( x \in \Omega \) and \( a_1, a_2 \in V \) and with \( |a_1| = |a_2| \) and \( v_1a_1x, v_2a_2x \in \Omega \).

(g) \( (\Omega, \sigma) \) is strongly exact transitive if and only if whenever \( v_1, v_2 \in V \) with \( |v_1| = |v_2| \), for all \( x \in \Omega \) there exist \( a_1, a_2 \in V \) with \( |a_1| = |a_2| \) and \( v_1a_1x, v_2a_2x \in \Omega \).

(h) \( (\Omega, \sigma) \) is strong product transitive if and only if whenever \( v_1, ..., v_n \in V \) with all of the same length, and \( x_1, ..., x_n \in \Omega \) there exist \( a_1, ..., a_n \) all of the same length such that \( v_1a_1x_1, ..., v_na_nx_n \in \Omega \).

(i) \( (\Omega, \sigma) \) is topologically mixing if and only if whenever \( v, w \in V \) there exists \( N \in \mathbb{N} \) such that for all \( k \in \mathbb{N} \) there exists \( a_k \in V \) with \( |a_k| = N + k \) and \( vax_kw \in V \).

(j) \( (\Omega, \sigma) \) is locally eventually onto if and only if whenever \( v \in V \), there is a finite collection \( V_v \subset V \) all of whose elements are of the same length such that if \( x \in \Omega \) there is an \( a \in V_v \) with \( vax \in \Omega \).

**Proof:** (a) : Given \( v, w \in V \) assume there always exists \( a \) such that \( vaw \in V \). Then there exists \( x \in \Omega \) which contains this word beginning at position \( i + 1 \) so \( \sigma^i(x) \in [v] \) and \( \sigma^{i+n}(x) \in [w] \) with \( n = |va| \). Hence, \( n \in N([v], [w]) \). Thus, \( (\Omega, \sigma) \) is topologically transitive.
Conversely, suppose $\Omega$ is topologically transitive and $x$ is a transitive point. Let $v, w \in \mathcal{V}$. Since $\sigma^n(x)$ is also a transitive point for $n > 0$ it follows that $v$ and $w$ appear infinitely often in $x$ so certainly a word of the form $vaw$ appears in $\Omega$.

(b) : The given condition says exactly that for each $v \in \mathcal{V}$, every $x \in \Omega$ occurs in some shift of the cylinder set $[v]$. Since the $[v]$’s form a basis, this implies very strong transitivity.

Conversely, if the system is very strongly transitive then $N([v], x)$ is infinite for every $v \in \mathcal{V}$ and $x \in X$. If $n \in N([v], x)$ with $n > |v|$ then there is a word $a$ of length $n - |v|$ such that $uax \in \Omega$.

(c) : Given any $N \in \mathbb{N}$ there are only finitely many words of length less than $N$. The given condition says exactly that for each $v \in \mathcal{V}$, every $x \in \Omega$ occurs in some shift of the cylinder set $[v]$ with an upper bound on the number of shifts required. This implies very strong transitivity.

Conversely, if the system is very strongly transitive, then given $v \in \mathcal{V}$ there exists $N \in \mathbb{N}$ such that $\bigcup_{k=1}^{N} \sigma^k([u]) = \Omega$. For every $x \in \Omega$, there exists $y \in \Omega$ such that $\sigma^{|v|+1}(y) = x$. Then $y \in \bigcup_{k=1}^{N} \sigma^k([u])$ and so $x \in \bigcup_{k=1}^{N+|v|+1} \sigma^k([v])$. This means there exists $a$ with $|a| \leq N$ such that $vax \in \Omega$.

(d) : If $(\Omega, \sigma)$ is minimal, $v \in \mathcal{V}$ and $x \in \Omega$ then the $\sigma$ orbit of $x$ enters $[v]$ and so $v$ occurs in $x$.

Conversely, if every word $v \in \mathcal{V}$ occurs in every $x \in \Omega$ then it occurs in every $\sigma^k(x)$ and so occurs in $x$ infinitely often. This implies that $\omega(x)$ meets every $[v]$ and so is dense. Hence, the closed set $\omega(x)$ equals $\Omega$ for every $x$. Thus, $(\Omega, \sigma)$ is minimal.

(e) : The given condition implies that for every $v_1, v_2, w \in \mathcal{V}$ with $|v_1| = |v_2|$, the hitting time set $N([v_1], [w]) \cap N([v], [w])$ is nonempty. Since $\{[v_1] \times [v_2] : |v_1| = |v_2|\}$ is a basis for $\Omega \times \Omega$, this implies that the system is weak mixing by the Petersen criterion, see [17].

Conversely, if the system is weak mixing then for every $v_1, v_2, w \in \mathcal{V}$ with $|v_1| = |v_2|$, the hitting time set $N([v_1], [w]) \cap N([v_2], [w])$ is infinite. If $n > |v_1| = |v_2|$ is in the intersection then there exist $a_1, a_2 \in \mathcal{V}$ with $|a_1| = |a_2| = n - |v|$ such that $v_1a_1w, v_2a_2 \in \mathcal{V}$.

(f), (g) : Proceed as in (e). We leave the details to the reader.

(h) : Proceed as in (c). We leave the details to the reader.

(i) : The condition is equivalent to the demand that $N([v], [w])$ is co-finite for every $v, w \in \mathcal{V}$.

(j) : If the common length of the elements of $\mathcal{V}$, is $n$ then $\sigma^{|v|+n}([v]) = \Omega$.
Conversely, if the system is locally eventually onto then for all sufficiently large \( N, \sigma^N([v]) = \Omega. \) If \( N > |v| \) then for every \( x \in \Omega \) there exists \( a \in \mathcal{V} \) with \( |a| = N - |v| \) such that \( vax \in \Omega. \) Let \( \mathcal{V}_v \) be all words of length \( N - |v| \).

\[ \blacksquare \]

Let \((X, f)\) and \((Y, g)\) be a dynamical systems. If \( \pi : X \to Y \) be a continuous surjection such that \( \pi \circ f = g \circ \pi \), then \( \pi : (X, f) \to (Y, g) \) is called a factor map, \((Y, g)\) is called a factor of \((X, f)\) and \((X, f)\) is called an extension of \((Y, g)\).

In [4] a property of a dynamical system is called residual when it is inherited by factors, by almost one-to-one lifts and is preserved by inverse limits. It is shown there that topological transitivity, minimality, weak mixing and mixing are residual properties. We now consider the remaining properties.

**Theorem 2.24** Let \( \pi : (X, f) \to (Y, g) \) be a factor map of dynamical systems.

(a) If \((X, f)\) is strongly transitive, very strongly transitive, exact transitive, strongly exact transitive, exact, strongly product transitive or locally eventually onto then \((Y, g)\) satisfies the corresponding property.

(b) Assume that \( \pi \) is almost one-to-one. If \((Y, g)\) is very strongly transitive or locally eventually onto then \((X, f)\) satisfies the corresponding property.

**Proof:** (a) Suppose \((X, f)\) is strongly transitive. Then for any open \( U \) in \( Y, \pi^{-1}(U) \) is open in \( X \) and so \( X = \bigcup_{n=1}^{\infty} f^n(\pi^{-1}(U)) \). It follows that

\[
Y = \pi(X) = \bigcup_{n=1}^{\infty} \pi f^n(\pi^{-1}(U)) = \bigcup_{n=1}^{\infty} g^n(\pi^{-1}(U)) = \bigcup_{n=1}^{\infty} g^n(U). \tag{2.2}
\]

Thus \((Y, g)\) is strongly transitive.

If \((X, f)\) is very strongly transitive, then we use the same proof with \( \bigcup_{n=1}^{\infty} f^n \) replaced by \( \bigcup_{n=1}^{N} f^n \) for sufficiently large \( N \) depending on \( \pi^{-1}(U) \) and obtain the result with \( \bigcup_{n=1}^{\infty} g^n \) replaced by \( \bigcup_{n=1}^{N} g^n \). If \((X, f)\) is locally eventually onto, we replace by \( f^{N} \) and \( g^{N} \).

The remaining properties are similarly proved using

\[ \pi[f^n(\pi^{-1}(U)) \cap f^n(\pi^{-1}(V))] \subset g^n(U) \cap g^n(V). \]
Now assume that \( \pi \) is almost one-to-one and that \( U \) is opene in \( X \). Let \( A \) be a closed set with nonempty interior. Let \( x \in A^o \cap \text{Inj}_\pi \). Since \( \pi \) is open at \( x \), there exists \( V \subset \pi(A^o) \) an open set containing \( \pi(x) \). If \((Y, g)\) is very strongly transitive then \( Y = \bigcup_{n=1}^N g^n(V) \) for some \( N \). Hence, \( Y = \pi(\bigcup_{n=1}^N f^n(A)) \). Because \( \bigcup_{n=1}^N f^n(A) \) is closed and \( \pi \) is irreducible, \( X = \bigcup_{n=1}^N f^n(A) \subset \bigcup_{n=1}^N f^n(U) \). Thus, \((X, f)\) is very strongly transitive.

If \((X, f)\) is locally eventually onto we replace \( \bigcup_{n=1}^N g^n(V) \) by \( g^N(V) \) and obtain \( X = f^N(U) \) by the same proof.

\[ \square \]

**Theorem 2.25**

(a) If \((X \times Y, f \times g)\) is strongly transitive, very strongly transitive, exact transitive, strongly exact transitive, exact, strongly product transitive or locally eventually onto then both \((X, f)\) and \((Y, g)\) satisfy the corresponding property.

(b) Assume \((Y, g)\) is mixing. If \((X, f)\) topologically transitive, weak mixing, or mixing then \((X \times Y, f \times g)\) satisfy the corresponding property.

(c) Assume \((Y, g)\) is locally eventually onto. If \((X, f)\) strongly transitive, very strongly transitive, exact, full exact, exact transitive, strongly exact transitive, strongly product transitive or locally eventually onto then \((X \times Y, f \times g)\) satisfy the corresponding property.

**Proof:** (a) Each projection is a factor map.

(b) Let \( U_1, V_1 \subset X \) and \( U, V \subset Y \) be opene. Since \((Y, g)\) is mixing \( N(U, V) \) is cofinal. Hence, \( N(U_1, V_1) \cap N(U, V) \) is infinite or cofinal if \( N(U_1, V_1) \) is. The product result follows for transitivity and mixing. Suppose \((X, f)\) is weak mixing. Then \((X \times X, f \times f)\) is topologically transitive and \((Y \times Y, g \times g)\) is mixing. Hence, \((X \times Y) \times (X \times Y), (f \times g) \times (f \times g)\) is topologically transitive. Thus, \((X \times Y, f \times g)\) is weak mixing.

(c) Let \( U_1 \subset X \) and \( U \subset Y \) be opene. There exist \( N \) so that \( n \geq N \) implies \( g^n(U) = Y \). If \( L \subset \mathbb{N} \) so that \( \bigcup\{f^n(U_1) : n \in L\} = X \) and there exists \( n \in L \) with \( n \geq N \) then \( \bigcup\{(f \times g)^n(U_1 \times U) : n \in L\} = X \times Y \). Using \( L = \mathbb{N} \) we obtain the result for strong topological transitivity. Using \( L = \{1, ..., N_1\} \) with \( N_1 \) sufficiently large, we obtain the result for very strong topological transitivity. Using \( L = \{N_1\} \) with \( N_1 \) sufficiently large, we obtain the result for locally eventually onto.

We leave the others as (easy) exercises.

\[ \square \]
Remark: We note that the products of strongly transitive or very strongly transitive systems need not be so. If \((X, f)\) is nontrivial and minimal with \(f\) a homeomorphism then it is very strongly transitive. The product \((X × X, f × f)\) is not minimal and so by Theorem 2.15 it is not strongly transitive.

We do not know whether strong transitivity is preserved by almost one-to-one lifts. On the other hand, most are not necessarily preserved by inverse limits.

Recall that for a surjective system \((X, f)\) the natural homeomorphism lift \((\hat{X}, \hat{f})\) is obtained by taking the inverse limit of the inverse sequence of systems \(\{p_n : (X_{n+1}, f_n) \to (X_n, f_n) \mid n \in \mathbb{N}\}\) with each \((X_n, f_n)\) a copy of \((X, f)\) and each \(p_n = f\). So \(\hat{x} \in \hat{X} \subset X^\mathbb{N}\) with \(\hat{x}_n = f(\hat{x}_{n+1})\) for all \(n \in \mathbb{N}\). The map \(\hat{f}\) is the restriction of the product map \(f^\mathbb{N}\) on \(X^\mathbb{N}\) to the closed invariant set \(\hat{X}\). Thus, \(\hat{f}\) is a homeomorphism with inverse the restriction of the shift map to \(\hat{X}\). Each projection \(\pi_n : (\hat{X}, \hat{f}) \to (X, f)\) is a factor map.

Now let \((X, f)\) be a nontrivial locally eventually onto system. So \((X, f)\) is full exact and so by Corollary 2.16 it is not minimal. The inverse limit system \((\hat{X}, \hat{f})\) is not exact since \(\hat{f}\) is a nontrivial homeomorphism. The system \((\hat{X}, \hat{f})\) is not minimal since its factor \((X, f)\) is not. So by Theorem 2.15 it is not strongly transitive.

An \(f : X \to X\) is called almost open if for every open \(U \subset X\), the interior \((f(U))^\circ\) is non-empty. An almost one-to-one map is almost open and so Corollary 2.16 implies that minimal maps are always almost open.

Example 2.26 A locally eventually onto map need not be almost open.

Let \(g\) be any continuous, surjective map on a compact perfect metric space \(Z\). Let \(F = g^\mathbb{N}\) on \(X = Z^\mathbb{N}\). That is, \(F(x)_i = g(x_i)\) for all \(i \in \mathbb{N}\). Notice that \(F\) is a continuous surjection on \(X\) and \(F\) commutes with the shift map \(\sigma\) on \(X\), since \((\sigma \circ F)(x)_i = g(x_{i+1}) = (F \circ \sigma)(x)_i\). Let \(f = \sigma \circ F = F \circ \sigma\). Then \((X, f)\) is locally eventually onto, as for any cylinder \([z] \subset X\), with \(|z| = k\), we have \(f^k([z]) = X\).

Now choose \(g\) so that it is not almost open, e.g. let \(Z = [0, 1]\) and let \(g(t) = 2t\) for \(t \in [0, \frac{1}{2}]\) and \(g(t) = 1\) for \(t \in [\frac{1}{2}, 1]\).

For any such \(g\) there exists a closed set \(K\) with nonempty interior \(U\) such that \(g(K)\) is nowhere dense. In the above example, \(K = [\frac{1}{2}, 1]\) will work. Consider in \(X\) the set \(\hat{K}\) of \(x\) such that \(x_2 \in K\). Observe that \(\{x : x_2 \in U\}\)
is open. \( f(\tilde{K}) = \{ x : x_1 \in g(K) \} \). Since \( g(K) \) is nowhere dense in \( Z \), \( f(\tilde{K}) \) is nowhere dense in \( X \).

\( \square \)

Let \((X, f)\) be any system, then \( f \) is called *iteratively almost open* if for every open \( U \subset X \) \( f^n(U)^\circ \neq \emptyset \) for infinitely many \( n \in \mathbb{N} \).

**Proposition 2.27** If \((X, f)\) is strongly transitive, then \( f \) is iteratively almost open.

**Proof:** Given open \( U \) choose a closed \( A \subset U \) with a nonempty interior. Since \( X = \bigcup_{n=1}^{\infty} f^n(A) \), the Baire Category Theorem implies that for some \( n \in \mathbb{N} \), \( f^n(A) \) contains a closed set \( B \) with a nonempty interior. Similarly, for some \( k \in \mathbb{N} \) \( f^k(B) \subset f^{i+k}(A) \) contains a closed set with a nonempty interior. Hence, \( f^n(U) \) has non empty interior for infinitely many \( n \in \mathbb{N} \).

\( \square \)

Let \( \mathcal{M} \) be the collection of closed non-empty negatively invariant subsets of \( X \) (note that \( X \in \mathcal{M} \)). A simple Zorn’s Lemma argument shows that any \( M \in \mathcal{M} \) contains a minimal element of \( \mathcal{M} \). We call the minimal elements of \( \mathcal{M} \) *negatively minimal sets*. From Lemma 2.11(d) it follows that a negatively minimal set is invariant. Clearly distinct negatively minimal sets are disjoint.

If \( x \in X \) we let \( M(x) \) denote the intersection of all closed – invariant sets which contain \( x \), while it is a minimum element among these sets it is not necessarily negatively minimal invariant as in the previous paragraph. The sets \( M(x) \) need not be disjoint. If \( f \) is an open map then \( M(x) \) is the closure of \( O^-(x) \) by Lemma 2.11(e). If \( x' \in M(x) \) then \( M(x') \subset M(x) \).

We observe that if \( M \) is a negatively minimal set, and \( x \in M \), then \( M(x) = M \). Moreover, if whenever \( x' \in M(x) \) we have \( M(x') = M(x) \) then \( M(x) \) is negatively minimal set.

Of course if \((X, f)\) is strongly transitive, then \( X \) is negatively minimal. If the map \( f \) is open, then the converse holds by Theorem 2.13.

Recall that point \( x \) is called *recurrent* when \( x \in \omega(x) \), i. e. for every open set \( U \) containing \( x \) there exist \( j \in \mathbb{N} \) such that \( f^j(x) \in U \).

**Theorem 2.28** If \((X, f)\) is strongly transitive but not minimal, then the set of non-recurrent points is dense in \( X \).
Proof: Let $M$ be a minimal subset of $X$ and $y \in M$. Since $(X, f)$ is not minimal $U = X \setminus M$ is open. Since $O^-(y)$ is dense, it meets $U$. Let $n$ be the smallest positive integer such that $f^{-n}(y) \cap U \neq \emptyset$ and let $x$ be a point of this intersection. Thus, $x \notin M$, but $f(x) \in f^{-(n-1)}(y) \subset M$. It follows that $\omega(x) = \omega(f(x)) \subset M$ and so $x$ is not recurrent. Since $M$ is + invariant, $O^-(x)$ is disjoint from $M$. On the other hand, for every point $z \in O^-(x)$, $\omega(z) = \omega(x) \subset M$ and so the points of the dense set $O^-(x)$ are non-recurrent.

\[\square\]

Corollary 2.29 A strongly transitive $(X, f)$ with all points recurrent is minimal.

\[\square\]

We say that $(X, f)$ has dense periodic sets if for every open $U$ there exists $N \in \mathbb{N}$ and $A \subset U$ closed such that $f^N(A) = A$.

Theorem 2.30 If $(X, f)$ is locally eventually onto then it has dense periodic sets.

Proof: Given $U$ open, let $V \subset U$ be closed with a nonempty interior. Since the system is locally eventually onto, there exists $N \in \mathbb{N}$ such that $f^N(V) = X \supset V$. This says that for the system $(X, f^N)$ the set $V$ is weakly − invariant. By Lemma 2.1 (d) $V$ contains a nonempty closed set $A$ which is invariant for $f^N$.

\[\square\]

On the other hand, the following example was given to us by Elon Lindenstrauss.

Example 2.31 A locally eventually onto map need not have any periodic points.

Let $(\hat{X}, \sigma)$ be an infinite minimal subshift of the full shift map $((1, 2)^\mathbb{N}, \sigma)$. Let $(X_0, \sigma)$ be the subshift of the full shift map $((0, 1, 2), \sigma)$ consisting of all sequences in which the word 00 does not occur. Thus, $(X_0, \sigma)$ is a subshift of finite type and the map $x \mapsto \hat{x}$ which excludes all the occurrences of 0
defines a continuous map $\pi$ from $X_0$ onto $\{1, 2\}^\mathbb{N}$. Similarly, for any finite word $u$ in the language of $X_0$ we define $\hat{u}$ to be the finite word with alphabet $\{1, 2\}$ obtained by excluding the 0's. Let $X = \pi^{-1}(\hat{X})$. While $\pi$ is not an action map, it is nonetheless clear that $X$ is an + and − invariant subset of $X_0$. For any word $\hat{u}$ in the language of $\hat{X}$ we obtain words $u$ in the language of $X$ by inserting 0's arbitrarily but with no repeats.

Since $\hat{X}$ contains no periodic points, is obvious that that $X$ does not. We now show that $(X, \sigma)$ is leo. It suffices to show that for any word $u$ in the alphabet of $X$, there exists $N \in \mathbb{N}$ such that $\sigma^N([u]) = X$. We may assume that $u$ has length $L$ at least two so that $\hat{u}$ has length $\hat{L} > 0$. Because $(\hat{X}, \sigma)$ is minimal, there exists $M \in \mathbb{N}$ such that

$$
\bigcup_{0 \leq k < M} \sigma^{-k}([\hat{u}]) = \hat{X}.
$$

Let $z \in X$ with $\pi(z) = \hat{z} \in \hat{X}$. Since the shift is surjective on $\hat{X}$ we can choose $\hat{w} \in \hat{X}$ such that $\sigma^{2M+\hat{L}}(\hat{w}) = \hat{z}$. There exists $k$ with $0 \leq k < M$ such that $\hat{x} = \sigma^k(\hat{w}) \in [\hat{u}]$. Thus, $\hat{x}$ is the concatenation $\hat{w}\hat{v}\hat{z}$ where $\hat{v}$ has length between $M + 1$ and $2M$. By inserting at most $M$ 0's without repeats between the endpoints, we can define a word $v$ in the language of $X$ with length exactly $2M$. Thus, $uvz \in [u] \subset X$ with $\sigma^{L+2M}(uvz) = z$. Since $z$ was arbitrary, $\sigma^N([u]) = X$ with $N = L + 2M$.

We have established

$$
\text{Locally Eventually Onto} \implies \text{Mixing} \implies \text{Strongly Product Transitive} \implies \text{Weak Mixing} \implies \text{Transitive}
$$

$$
\text{Strongly Product Transitive} \Downarrow
$$

$$
\text{Exact Transitive} \Downarrow \implies \text{Strongly Exact Transitive} \Downarrow \implies \text{Transitive}
$$

$$
\text{Transitive} \iff \text{Strongly Transitive} \iff \text{Very Strongly Transitive} \iff \text{Minimal} \iff \text{Locally Eventually Onto}
$$

The reverse implications do not hold for most of these.

**Proposition 2.32** The following statements hold:
1. Mixing $\not\Rightarrow$ Strongly Transitive, Exact Transitive or Minimal.

2. Very Strongly Transitive $\not\Rightarrow$ Minimal.

3. Minimal $\not\Rightarrow$ Exact Transitive or Weak Mixing.

4. Strongly Product Transitive & Mixing $\not\Rightarrow$ Very Strongly Transitive.

5. Exact Transitive & Mixing $\not\Rightarrow$ Strongly Transitive.

6. Weak Mixing $\not\Rightarrow$ Mixing.

**Proof:** We prove each of these statements by providing examples.

1. & 2. The full shift $\sigma$ on $\Omega = \{0, 1\}^\mathbb{Z}$ is a mixing homeomorphism which is not minimal. Since it is injective, it is not exact. By Theorem 2.15 it is not ST because it is not minimal. The full shift on $\{0, 1\}^\mathbb{N}$ is LEO and so is VST but not minimal.

3. Let $R_\alpha$ be an irrational rotation on the unit circle $S^1$. The map $R_\alpha$ is a minimal, isometric homeomorphism. Hence, it is VST but is not exact or weak mixing.

4. Let $(\Omega, \sigma)$ be subshift on the closure of all sequences of the form

$$0^k1^{t_1}0^{3^{n_1}}1^{t_2}0^{3^{n_2}}1^{t_3}0^{3^{n_3}} \ldots 1^{t_i}0^{3^{n_i}} \ldots, k \geq 0, t_i, n_i \in \mathbb{N}$$

in $\{0, 1\}^\mathbb{N}$. This is SPT and Mixing but not VST. To see this, one shows that if $v$ is a word in the language of $\Omega$ and $x \in \Omega$ there exists $N$, depending on $v$ and $x$, such that for every $n \geq N$ there exists a word $a$ of length $n$ such that $vax \in \Omega$. This implies SPT and Mixing. On the other hand, as $x$ varies, the minimum length $N$ is not bounded and this implies that the system is not VST.

5. Let $S = \{a_i, b_i : i \in \mathbb{Z}\}$ consist of two bi-infinite sequences in $(0, 1)$, with $b_{i-1} < a_i < b_i < a_{i+1}$ for all $i \in \mathbb{Z}$ with $a_i, b_i \to 0, 1$ as $i \to \mp \infty$. Let $J_i^+ = [a_i, b_i]$, $J_i^- = [b_i, a_{i+1}]$ for $i \in \mathbb{Z}$. with $J_i^{\pm, 0}$ the corresponding open intervals.

Define: $f$ on $[0, 1]$ so that

$$0 \mapsto 0, \ a_i \mapsto a_{i-1}, \ b_i \mapsto b_{i+1}, \ 1 \mapsto 1$$

and $f$ is linear on each $J_i^{\pm}$. The points 0 and 1 are fixed points with singleton pre-images.
Thus, \( f \) is monotone increasing on each \( J_i^+ \), decreasing on each \( J_i^- \) and the slope on each interval has absolute value greater than one. Observe that \( f \) is monotone on a closed interval \( J \) iff \( J^0 \) is disjoint from \( S \).

Clearly, \( f(J^-_i) \supset J^+_i \)

and

\[
f([a_{i-k}, b_{i+k}]) \supset [a_{i-(k+1)}, b_{i+(k+1)}] \supset [a_{i-k}, b_{i+k}]
\]

for all \( i \in \mathbb{Z} \) and \( k = 0, 1, 2, \ldots \).

Thus, for each \( i \in \mathbb{Z} \) the sequence of intervals \( \{f^k(J^+_i) : k = 0, 1, \ldots \} \) is increasing with union \((0,1)\).

**Lemma 2.33** If \( J, K \) are closed, nontrivial intervals in \((0,1)\) then there exists \( N \in \mathbb{N} \) so that \( f^k(J) \supset K \) for all \( k \geq N \).

**Proof:** If some iterate of \( J \) contains some \( b_i \) and \( a_j \) then it contains either \( J_i^+ \) or \( J_i^- \) and the result then follows using the increasing sequence \( \{f^k(J_i^+)\} \).

If it contains either two \( b_i \)'s or two \( a_j \)'s then it contains some \( b_i \) and some \( a_j \). Thus, it suffices to show that some iterate of \( J \) meets \( S \) in at least two points.

First we show that if \( G \) is a nonempty open interval in \((0,1)\) then some iterate of \( G \) meets \( S \). Assume not. Then, inductively, each \( f^k(G) \) is an interval contained in some \( J_{i}^{\pm,0} \) and so it is an open interval on which \( f \) is monotone. As the slopes have absolute value greater than one, the lengths are increasing. On the other hand, for any \( \epsilon > 0 \) there are only finitely many \( J_i^{\pm} \) with length greater than or equal to \( \epsilon \). So with \( \epsilon \) equal to the length of \( G \), each \( f^k(G) \) is contained in one of this finite collection. On a finite collection of \( J_{i}^{\pm} \)'s the absolute value of the slopes is bounded above one. Hence, the lengths must be increasing at least at a geometric rate and this is impossible in \([0,1)\).

Thus, we obtain that some iterate of \( G \) contains a nontrivial closed interval \([c, d]\) with either \( c \) or \( d \) in \( S \). By the previous argument, \( f^k((c, d)) \) meets \( S \) for some \( k = 0, 1, \ldots \). Let \( k \) be the smallest such nonnegative integer. Then on \([c, d]\) the map \( f^k \) is injective. Hence, the point \( e \in f^k((c, d)) \cap S \) is not equal to either \( f^k(c) \) or \( f^k(d) \) one of which also lies in \( S \).

Thus, as required we have shown that some iterate of a nontrivial interval meets \( S \) in at least two places.

It follows that \( f \) is exact transitive and topologically mixing. Since, \( \mathcal{O}^{-}(0) = \{0\} \) and \( \mathcal{O}^{-}(1) = \{1\} \), the system is not ST.
6. It is well-known that there are weak mixing homeomorphisms which
are not mixing. For shift examples see [4].

We are left with the following questions:

• Does Strongly Exact Transitive $\Rightarrow$ Strongly Product Transitive?

• Does Strongly Product Transitive $\Rightarrow$ Mixing?

• Does Exact Transitive $\Rightarrow$ Mixing?

Our example in 5. above yields a transitive map on $[0, 1]$ such that the
two endpoints have singleton backward orbits; whereas backward orbits of
all other points are dense. This is similar to an example given in [7].

The same example when restricted to the open interval $(0, 1)$ can be used
to provide a transitive map on $\mathbb{R}$ with all points having dense backward
orbits. An example of a transitive map on $\mathbb{R}$ such that $f^{-1}(0) = \{0\}$ and all
other backward orbits are dense has been constructed in [15]. It has been
also proved that there can be at most one such point, whose backward orbit
is not dense, for any transitive map on $\mathbb{R}$ in [14].

Towards the end, it would also be interesting to look into noninvertible,
minimal subshifts. Observe that given any minimal subshift $\Psi \subset A^\mathbb{Z}$, where
$A$ is a finite alphabet, we can define a subshift $\Omega \subset A^\mathbb{N}$, by taking the
projection $\pi : \Psi \rightarrow \Omega$ induced by the inclusion of $\mathbb{N}$ into $\mathbb{Z}$. As a factor of
a minimal system, $(\Omega, \sigma)$ is minimal. If this system is infinite, then it will
contain asymptotic pairs of points, see, e.g. [5] page 19. Beginning with such
a pair and shifting we can obtain $u, v \in \Omega$ such that $u_0 \neq v_0$, but $u_n = v_n$
for all $n \in \mathbb{N}$. Thus, $\sigma$ is not invertible on $\Omega$.

We refer the reader to [12] for more on noninvertible minimal maps.
