2Odessa State Academy of civil engineering and architecture, 65029 Odessa, Ukraine

Abstract. The article examines the level of sustainable development of the travel business in the Odessa region of Ukraine. This level is evaluated as a latent indicator, which is characterized by a certain set of signs-symptoms. The methodology used for modeling is Partial Least Squares-Path Modelling (or PLS-PM) and the method Time-Wise Multi-Way Principal Component Analysis. This approach allowed us to identify and evaluate latent and explicit factors affecting the sustainable development of travel business in the Odessa region.

Keywords: travel business, sustainable development, Time-Wise Multi-Way Principal Component Analysis, Partial Least Squares-Path Modelling

1 Introduction

In recent years, there has been a reorientation of the main goals of the business. Previously, the main task of business was to obtain the greatest possible profit, now stable development is taking priority. A lot of research has been devoted to the issues of sustainable development of the travel business, among which we mention works [1-8]. The problem of quantitative assessment of the level of stable development of the tourism business is especially urgent. To solve it, it is necessary to apply the methods of mathematical modeling. A number of works are devoted to these questions [9-17]. Many economic indicators (such as development stability, competitiveness, investment attractiveness, efficiency, etc.) are latent, clearly unmeasured. Therefore, it becomes necessary to use special methods for their evaluation. This work is devoted to assessing the level of sustainable development of the tourism business in the Odessa region using special methods of multivariate statistical analysis. It should be noted that the Odessa region has strong potential for sustainable development. Among the many factors influencing this, we note the following: the presence of an extended line of the Black Sea coast, the presence of a developed infrastructure (sea and river ports, an international airport), sanatoriums, rest houses, cultural attractions, etc. Unfortunately, in 2020, the tourism business in the Odessa region (due to COVID-19) practically ceased to function normally (like all over the world).

2 Materials and methods

Data for analysis is available on the website of the State Statistics Service of Ukraine (regional statistics) and Main Department of Statistics in Odessa region [18, 19]. The time period for which the data will be available starting from 2010 and ending in 2019. Preliminary data processing was carried out in MS Excel spreadsheets. When modelling and computing was used the following tools: a package for component analysis (PCA-PM) of Statistica12 [8], and program XLSTAT (a package XLSTAT-PLSPM for analysis using the least partial square method PLS-PM: Partial Least Squares Path Modelling or Projection on the Latent Structures Path Modelling). PLS-PM methods started to be widely used in a variety of applied researches of the 70-s years of the twentieth century because of the work of Herman Wold and his son Sven Wold, in this works the basic principles of the technique of modelling PLS–PM were established. PLS-PM is a tool for modelling of interconnections between latent variables. The method PLS-PM is used for analyses of high dimensional data in the conditions of ill-structured environment. It is widely applied, in particular, in the economy to evaluate such latent indexes as a utility, level of economic development, etc. Following, the task of modelling by the method of PLS-PM can be described as follows: let \( X \) is a \( n \times p \) data matrix:

\[
X = \begin{pmatrix}
  x_{11} & x_{12} & \cdots & x_{1p} \\
  x_{21} & x_{22} & \cdots & x_{2p} \\
  \vdots  & \vdots  & \ddots & \vdots  \\
  x_{n1} & x_{n2} & \cdots & x_{np}
\end{pmatrix},
\]

where \( n \) is the number of observations (objects), and \( p \) is the number of variables (characteristics). The matrix \( X \) can be divided into \( l \) blocks \( X_j, j = 1, l \), each of which \( X_j \) is associated with a latent variable \( LV_j \), the estimate of which is denoted \( Y_j = LV_j \). All interconnections between variables can be divided into two types: interconnections between latent variables \( LV_j \) and blocks \( X_j \) (these interconnections form the outer model) and interconnections between the latent variables with each other (these interconnections form the internal model). Internal model can be written in the form of a system of linear equations:

\[
LV_j = \beta_0 + \sum_{i \rightarrow j} \beta_{ji} LV_i + \epsilon_j^{in},
\]

where \( LV_i \) is all latent variables that affect the latent variable \( LV_j \); \( \beta_{ji} \) are structural coefficients that characterize the force and the direction of connection between latent variables \( LV_i \) and \( LV_j \); \( \beta_0 \) - free member; \( \epsilon_j^{in} \) - a random deviation of the internal model. The internal model imposed by the following requirements:

1. The system of latent equations should be recursive so it has to correspond to loop-free graph.
2. Internal model is recursive, so the following requirement is true:
\[ E(LV_j \mid LV_i) = \beta_{0i} + \sum_{i \to j} \beta_j L V_i. \]

3. Random deviation are independent of the explanatory variables, that is, the following requirement is satisfied: \( \text{cov}(LV_j, \varepsilon_j) = 0 \).

Thus, at the simulation by using the method of projection on the latent structure the requirements for the statistical distributions of variables and random deviations are absent. The external model describes two type of interconnection between latent and explicit variables: reflective and formative. Reflective type is the most widespread type of external models in which the latent variable is the cause of implicit variables, that is, explicit variables reflect latent. The external model can be written in the form of a system of linear equations:

\[ x_{jk} = \lambda_{0jk} + \lambda_{jk} LV_j + \varepsilon_{jk}^{\text{out}}; \]  

(2)

where \( \lambda_{jk} \) are load coefficients, \( \lambda_{0jk} \) are free members, \( \varepsilon_{jk}^{\text{out}} \) is random deviation of the external model. Formative type is a kind of external model when explicit variables are "cause" of latent variables, i.e. they «form» latent variables. External formative model can be represented in the form of a system of linear equations:

\[ LV_j = \lambda_{0j} + \lambda_{jk} x_j + \varepsilon_{j}^{\text{out}}; \]  

(3)

where \( \lambda_{jk} \) are load coefficients, \( \lambda_{0j} \) are free members, \( \varepsilon_{j}^{\text{out}} \) is random deviation of the external model. Latent variables can not be measured directly. Therefore we enter the notion of evaluation of latent variable \( Y_j = LV_j \), which is a linear combination of the corresponding implicit variables: \( Y_j = \sum_k w_{jk} x_j \), where \( w_{jk} \) - external weight (weight multipliers) of the model. Thus, variables \( LV_j \) and \( Y_j = LV_j \) characterize one and the same entity, but are used in different purposes: the first is for theoretical, the other is for practical.

PLS-PM modelling can be represented as a three-steps algorithm:

a) calculating of external weights \( w_{jk} \) to obtain estimates of the latent variables;

b) computation of structural coefficients \( \beta_{jk} \) of internal model;

c) calculation of loads \( \lambda_{jk} \) of external model.

The first step is the main and the most complicate step of PLS-PM methodology, that is iteration, its purpose is to calculate the values of external measures and, as a result, ratings \( Y_j \). The result of this step is that abstract latent variables materialize. The second step is solution of a system of linear equations by the method of least squares, the third is calculation of correlations \( \lambda_{jk} = \text{cor}(x_{jk}, Y_j) \).
3 Results and Discussion

Building PLS-PM for the model of sustainable development of travel business for Odessa region. The following table presents indicators of sustainable travel business development:

| Indicator                          | Description of the indicator                                      | Notation |
|------------------------------------|-------------------------------------------------------------------|----------|
| Number of tourists                 | Total number of tourists per calendar year                        | $x_{11}$ |
| Wage of employees in the service sector | Total wage of employees in the service sector per calendar year | $x_{12}$ |
| Number of travel company           | Number of travel company in region                                | $x_{13}$ |
| Tax revenues from the travel industry | Total tax revenues from the travel industry for calendar year    | $x_{14}$ |
| Subsidies for the population       | Total subsidies for the population per calendar year              | $x_{21}$ |
| State cost on social services for the population | The sum of state cost on the protection of public safety, health and other social services for a year | $x_{22}$ |
| The unemployment rate              | The proportion of the total number of unemployed persons to the economically active population | $x_{23}$ |
| Emissions of pollutants into atmospheric air | Quantity of the emissions of pollutants into atmospheric air in region | $x_{31}$ |
| Wastes generation                  | Quantity of the wastes generation in region                       | $x_{32}$ |
| State cost on the protection of the environment | The sum of state cost for the protection of the environment per calendar year | $x_{33}$ |
| Current expenditures on environmental | Costs on environmental per calendar year                        | $x_{34}$ |
| Gross Regional Product            | Value of the GRP per calendar year                               | $x_{41}$ |
### Table 1. Indicators of sustainable travel business development

| Indicator                          | Description of the indicator                              | Notation |
|------------------------------------|-----------------------------------------------------------|-----------|
| Number of tourists                 | Total number of tourists per calendar year                | 11\(_X\) |
| Wage of employees                  | Total wage of employees in the service sector per calendar year | 12\(_X\) |
| Number of travel company           | Number of travel company in region                         | 13\(_X\) |
| Tax revenues                       | Total tax revenues from the travel industry for calendar year | 14\(_X\) |
| Subsidies for the population       | Total subsidies for the population per calendar year      | 21\(_X\) |
| State cost on social services      | The sum of state cost on the protection of public safety, health and other social services for a year | 22\(_X\) |
| The unemployment rate              | The proportion of the total number of unemployed persons to the economically active population | 23\(_X\) |
| Emissions of pollutants into atmospheric air | Quantity of the emissions of pollutants into atmospheric air in region | 31\(_X\) |
| Waste generation                   | Quantity of the wastes generation in region               | 32\(_X\) |
| State cost on the protection of the environment | The sum of state cost for the protection of the environment per calendar year | 33\(_X\) |
| Current expenditures on environmental cost | Costs on environmental per calendar year | 34\(_X\) |
| Gross Regional Product            | Value of the GRP per calendar year                          | 41\(_X\) |
| State spending on economic development | State spending on economic development per calendar year | 42\(_X\) |
| Utility Costs                      | The amount of the state cost for utility bills populated | 43\(_X\) |
| Total income                       | Total population income for a calendar year                | 44\(_X\) |

Source: Own processing.

Note that these indicators of sustainable development of the tourism business were selected from a large number of factors affecting the stable development of the region.

Following the works [20-22], we build a hierarchical structural model. The original model is represented in the following Figure 1. Latent variables: LV\(_1\) - level of sustainable development of the tourism business, LV\(_2\) – level of social condition, LV\(_3\) - level of the environmental protection, LV\(_4\) – condition of economics are denoted by ovals, and explicit variables (indicators from a table) by rectangles.

![Fig. 1. Schematic representation of the basic model.](source: Own processing with XLSTAT-PM)

The relationship of the latent variables is the internal model, and the relationships between latent and explicit variables represent an external model. Let’s write these models in analytical form. The internal model: \( LV_1 = \beta_0 + \beta_2 LV_2 + \beta_3 LV_3 + \beta_4 LV_4 + \epsilon_1 \), where
$LV_j$ - latent variables; $\beta_2, \beta_3, \beta_4$ - structural coefficients, which characterize the strength and direction of the interconnection between latent variables, $\beta_0$ - free member and $\epsilon_1$ is residual. The external model looks like the following system:

$$
\begin{align*}
    x_{11} &= \lambda_{01} + \lambda_{11} LV_1 + \epsilon_{11} \\
    \ldots & \quad ; \\
    x_{44} &= \lambda_{04} + \lambda_{44} LV_4 + \epsilon_{44}
\end{align*}
$$

(4)

where $x_{11}, \ldots, x_{44}$ are explicit variables, $\lambda_{11}, \ldots, \lambda_{44}$ are coefficients of loads, $\lambda_{01}, \ldots, \lambda_{04}$ - free members, $\epsilon_{11}, \ldots, \epsilon_{44}$ - residuals. Note that at structural coefficients simulating by means of the partial least squares (PLS) we use the estimations of latent variables: $Y_j = LV_j = \sum w_{jk} x_{jk}$. For our model, these estimations can be presented in the form of the following system of equations:

$$
\begin{align*}
    Y_1 &= w_{11} x_{11} + w_{12} x_{12} + w_{13} x_{13} + w_{14} x_{14} \\
    Y_2 &= w_{21} x_{21} + w_{22} x_{22} + w_{23} x_{23} \\
    Y_3 &= w_{31} x_{31} + w_{32} x_{32} + w_{33} x_{33} + w_{34} x_{34} \\
    Y_4 &= w_{41} x_{41} + w_{42} x_{42} + w_{43} x_{43} + w_{44} x_{44}
\end{align*}
$$

(5)

where $w_{11}, \ldots, w_{44}$ are external weights of the model.

Let’s check correctness of breaking the X matrix of raw data into 4 blocks $X_1, X_2, X_3, X_4$ (which corresponds to latent components $LV_1, LV_2, LV_3, LV_4$). The method Time-Wise Multi-Way Principal Component Analysis (TMPCA) is applicable. We calculate using the appropriate module of the Statistica. Note that variables should be standardized before analysis ($z_{ij} = \frac{x_{ij} - \bar{x}_{ij}}{\sigma_j}, \quad i = 1, 10; \quad j = 1, 15$). This brings all variables to dimensionless values with mean values of 0 and standard deviations of 1. For the analysis, we use the following results of the module TMPCA:
latent variables; structural coefficients, which characterize the strength and direction of the interconnection between latent variables, are free members and residuals.

The external model looks like the following system:

\[
\begin{align*}
\mathbf{y} &= \mathbf{X}\mathbf{B} + \mathbf{e} \\
\mathbf{X} &= \mathbf{L}\mathbf{w} + \mathbf{r}
\end{align*}
\]

where \(\mathbf{X}\), \(\mathbf{L}\), and \(\mathbf{w}\) are explicit variables, coefficients of loads, and free members, respectively. \(\mathbf{e}\) and \(\mathbf{r}\) are residuals.

Note that structural coefficients simulating by means of the partial least squares (PLS) we use the estimations of latent variables:

\[
\hat{y}_{jk} = \sum_{i=1}^{4} \mathbf{y}_{ij} w_{ij} x_{ij}
\]

For our model, these estimations can be presented in the form of the following system of equations:

\[
\begin{align*}
\mathbf{y}_1 &= \mathbf{X}_1\mathbf{B}_1 + \mathbf{e}_1 \\
\mathbf{y}_2 &= \mathbf{X}_2\mathbf{B}_2 + \mathbf{e}_2 \\
\mathbf{y}_3 &= \mathbf{X}_3\mathbf{B}_3 + \mathbf{e}_3 \\
\mathbf{y}_4 &= \mathbf{X}_4\mathbf{B}_4 + \mathbf{e}_4
\end{align*}
\]

where \(\mathbf{X}_i\), \(\mathbf{B}_i\), and \(\mathbf{w}_i\) are external weights of the model.

Let’s check correctness of breaking the \(\mathbf{X}\) matrix of raw data into 4 blocks \(\mathbf{X}_1, \mathbf{X}_2, \mathbf{X}_3, \mathbf{X}_4\) (which corresponds to latent components \(\mathbf{LV}_1, \mathbf{LV}_2, \mathbf{LV}_3, \mathbf{LV}_4\)). The method Time-Wise Multi-Way Principal Component Analysis (TMPCA) is applicable. We calculate using the appropriate module of the Statistica.

Note that variables should be standardized before analysis, (1, 10; 1, 15) \(\frac{\mathbf{y}_{ij} - \mu_{ij}}{\sigma_{ij}} = \mathbf{z}_{ij}\). This brings all variables to dimensionless values with mean values of 0 and standard deviations of 1.

For the analysis, we use the following results of the module TMPCA:

![Scree plot for eigenvalues](image)

**Fig. 2.** Screen plot for eigenvalues.
Source: Own processing with Statistica.

**Table 2.** Eigenvalues and percentage contribution of PCA at the total variation of components \(\mathbf{LV}_1, \mathbf{LV}_2, \mathbf{LV}_3, \mathbf{LV}_4\)

| Components | Eigenvalue | % Total Variance | Accumulated % |
|------------|------------|------------------|---------------|
| \(\mathbf{LV}_1\) | 3.67872 | 39.76 | 39.76 |
| \(\mathbf{LV}_2\) | 2.499577 | 26.66 | 66.42 |
| \(\mathbf{LV}_3\) | 2.3032 | 14.48 | 80.9 |
| \(\mathbf{LV}_4\) | 1.8732 | 9.7 | 90.6 |

Source: Own processing with Statistica.

Figure 2 and Table 2 show that the components-factors \(\mathbf{LV}_1, \mathbf{LV}_2, \mathbf{LV}_3, \mathbf{LV}_4\) selected for modeling provide more than 90% of the total variation.

Analyses of the model by PLS-PM includes the following items: a) verification of the internal consistency of the blocks; b) verification of significance of variables in the external model; c) verification of cross correlations of variables in block with latent variables of other blocks; d) verification of the internal model; e) verification of the model qualification by index of conformity of model to data.

Step a). The following criteria are used to verify internal consistency in blocks: Cronbach-alpha (\(\alpha\)) and Dillon-Goldstein (\(\rho\)) coefficients (see, for example, [20-22]), as well as eigenvalues \(\hat{\lambda}_i\) of the correlation matrix of explicit variables (indicators).
Table 3. Checking internal consistency in blocks

| Block | $\alpha$ | $\rho$ | $\lambda_1$ | $\lambda_2$ |
|-------|---------|-------|-------------|-------------|
| LV$_4$ | 0.8843  | 0.9123 | 1.87        | 0.72        |
| LV$_3$ | 0.1009  | 0.0912 | 2.3         | 0.73        |
| LV$_2$ | 0.2012  | 0.5809 | 2.50        | 0.38        |
| LV$_1$ | 0.8547  | 0.9035 | 3.68        | 0.70        |

Source: Own processing with XLSTAT-PM.

The Table 3 shows that the two blocks (LV$_4$ and LV$_1$) have good $\alpha > 0.7$ and $\rho > 0.7$ coefficients. But the LV$_3$ and LV$_2$ blocks have poor internal consistency ($\alpha, \rho < 0.7$). The following Table 4 shows the correlation coefficients of explicit and latent variables for each of the blocks.

Table 4. The correlation coefficients of explicit and latent variables for each of the blocks

| Block | Variables
|-------|----------------|
|       | $x_{31}$ | $x_{32}$ | $x_{33}$ | $x_{34}$ |
| LV$_3$ | -0.8234 | -0.9123 | 0.9546 | 0.8756 |
| LV$_2$ | 0.8947  | 0.9035  | -0.8759 |

Source: Own processing with XLSTAT-PM.

In the block LV$_3$ two variables ($x_{31}$ and $x_{32}$) have a negative correlation with latent variable. In the LV$_2$ also there is a variable with negative correlation ($x_{23}$). This leads to internal inconsistencies in blocks, since these indicators are so-called de-stimulators (the higher their values, the worse). For the correct application of multivariate statistical analysis methods, it is recommended to make all indicators unidirectional (as a rule, stimulants). Therefore, we will make a replacement: $x_{31}' = 1 - x_{31}$, $x_{32}' = 1 - x_{32}$, $x_{23}' = 1 - x_{23}$. After modification of variables we obtain the index of cooperation of external model, are presented in the following Table 5:
Table 3. Checking internal consistency in blocks

| Block | \( \alpha \) | \( \rho \) | \( \lambda_1 \) | \( \lambda_2 \) |
|-------|-----------|-----------|-------------|-------------|
| LV_4  | 0.8802    | 0.9113    | 1.87        | 0.72        |
| LV_3  | 0.8854    | 0.9463    | 2.3         | 0.73        |
| LV_2  | 0.8567    | 0.9347    | 2.50        | 0.38        |
| LV_1  | 0.8573    | 0.9086    | 3.68        | 0.70        |

Source: Own processing with XLSTAT-PM.

The Table 3 shows that the two blocks (LV_4 and LV_1) have good coefficients. But the LV_3 and LV_2 blocks have poor internal consistency (\( \alpha, \rho \gtrsim obligation). The following Table 4 shows the correlation coefficients of explicit and latent variables for each of the blocks.

Table 4. The correlation coefficients of explicit and latent variables for each of the blocks

| Block | \( x_{31} \) | \( x_{32} \) | \( x_{33} \) | \( x_{34} \) |
|-------|-------------|-------------|-------------|-------------|
| LV_3  | 0.3274      | 0.9163      | 0.3047      | 0.8132      |
| LV_2  | 0.3274      | 0.9045      | 0.4382      | 0.9134      |
| LV_1  | 0.3468      | 0.9768      | 0.2173      | 0.7688      |

Step b). The second phase is verification of the external model:

Table 5. Cooperation indexes of the external model

| Block | \( \alpha \) | \( \rho \) | \( \lambda_1 \) | \( \lambda_2 \) |
|-------|-----------|-----------|-------------|-------------|
| LV_4  | 0.8802    | 0.9113    | 1.87        | 0.72        |
| LV_3  | 0.8854    | 0.9463    | 2.3         | 0.73        |
| LV_2  | 0.8567    | 0.9347    | 2.50        | 0.38        |
| LV_1  | 0.8573    | 0.9086    | 3.68        | 0.70        |

Source: Own processing with XLSTAT-PM.

All three of the cooperation criterions satisfy the necessary (\( \alpha, \rho > 0.7, \lambda_1 > 1, \lambda_2 < 1 \)).

Step b). The second phase is verification of the external model:

Table 6. The value of the coefficients of the external model

| Block | Variable | External weight \( w_j \) | Load \( \lambda_{ij} \) |
|-------|----------|---------------------------|----------------------|
| LV_4  | \( x_{41} \) | 0.5347                    | 0.2678               |
|       | \( x_{42} \) | 0.4342                    | 0.8473               |
|       | \( x_{43} \) | 0.3245                    | 0.4565               |
|       | \( x_{44} \) | 0.3641                    | 0.3172               |
| LV_3  | \( x_{31} \) | 0.3274                    | 0.9163               |
|       | \( x_{32} \) | 0.3047                    | 0.8132               |
|       | \( x_{33} \) | 0.2679                    | 0.9024               |
|       | \( x_{34} \) | 0.2473                    | 0.8271               |
| LV_2  | \( x_{21} \) | 0.3274                    | 0.9045               |
|       | \( x_{22} \) | 0.4382                    | 0.9134               |
|       | \( x_{23} \) | 0.3645                    | 0.8356               |
| LV_1  | \( x_{11} \) | 0.3468                    | 0.9768               |
|       | \( x_{12} \) | 0.2173                    | 0.7688               |

Variables are considered significant if the load factor $\hat{\lambda}_{i,j} > 0.7$. By the results of the model validation it is necessary to eliminate variables $x_{13}, x_{41}, x_{43}, x_{44}$. After exclusion of nonsignificant variables we get the following test results of external model:

**Table 7.** The value of the coefficients of the external model after modifications

| Block | Variable | External weight $w_j$ | Load $\hat{\lambda}_{i,j}$ |
|-------|----------|----------------------|----------------------------|
| LV4   | $x_{42}$ | 0.3769               | 0.9151                     |
| LV3   | 1-$x_{31}$ | 0.3453             | 0.9273                     |
|       | 1-$x_{32}$ | 0.3048             | 0.8601                     |
|       | $x_{33}$  | 0.2869             | 0.9041                     |
|       | $x_{34}$  | 0.2283             | 0.8171                     |
| LV2   | $x_{21}$  | 0.3394            | 0.9032                     |
|       | $x_{22}$  | 0.4192            | 0.9081                     |
|       | 1-$x_{23}$ | 0.3586             | 0.8576                     |
| LV1   | $x_{11}$  | 0.4071            | 0.9879                     |
|       | $x_{12}$  | 0.2412            | 0.7697                     |
|       | $x_{14}$  | 0.4394            | 0.9677                     |

After checking the load factors $\hat{\lambda}_{i,j}$, that is, after checking the interconnection of explicit variables with latent variable of the corresponding block, you need to check the cross-loading, i.e. to determine the strength of the connection between explicit variables and latent variables of other blocks. This will exclude such indicators whose connection with latent variable of another block is greater than with latent variable of the corresponding block. The Table 8 shows that the strength of the connection of all explicit variables with latent variables of corresponding blocks is greater than with latent variables of other blocks, that is, all variables are "loyal" to their blocks.
The next step is to check the quality of the internal model. In the Table 9 are estimates $\beta_i$ of the equations of structural model, as well as the results of the criterion-statistics.

**Table 9.** Estimation of the parameters $\beta_i$ of a structural model

| Block | Variable | Estimation | Standard error | t-statistics | Pr(>|t|) |
|-------|----------|------------|----------------|--------------|---------|
| LV4   | $x_{42}$ | 0.9071     | -0.0750        | 0.0934       | 0.4374  |
|       | $x_{31}$ | 0.3149     | 0.9273         | 0.5768       | 0.8091  |
|       | $x_{32}$ | 0.2133     | 0.8081         | 0.5638       | 0.7283  |
|       | $x_{33}$ | -0.5463    | 0.9023         | 0.6475       | 0.7205  |
|       | $x_{34}$ | -0.3148    | 0.8087         | 0.6405       | 0.5586  |
| LV3   | $x_{21}$ | -0.0384    | 0.5768         | 0.9120       | 0.6879  |
|       | $x_{22}$ | -0.1061    | 0.7495         | 0.9071       | 0.8412  |
|       | $x_{23}$ | -0.0834    | 0.5205         | 0.8586       | 0.7225  |
| LV2   | $x_{11}$ | -0.2412    | 0.8364         | 0.8031       | 0.9879  |
|       | $x_{12}$ | 0.0945     | 0.4273         | 0.6814       | 0.7907  |
|       | $x_{14}$ | -0.2927    | 0.2489         | 0.8506       | 0.9687  |
| LV1   | $x_{11}$ | -0.2412    | 0.8364         | 0.8031       | 0.9879  |

Criterion of t-statistics is held for blocks LV3 and LV2 (Pr(>|t|)<0.05), but not to block LV4 (Pr(>|t|)>0.05). Following the criterion of t-statistics, the latent factor LV4 should be excluded from consideration. But we decided to leave it in the model. After all, the impact of the level of economic development of the region on the environment and the level of social development is obvious. Our hierarchical model did not take into account the relationship between latent factors LV4, LV3 and LV2. The following Table 10 presents summary statistics for the structural model.
Table 10. Total statistic of internal model

| Block | R²   | Ratio explanation variation | Ratio rejecting variation AVE |
|-------|------|------------------------------|------------------------------|
| LV₄   | 0.00 | 0.79                         | 0.89                         |
| LV₃   | 0.00 | 0.85                         | 0.75                         |
| LV₂   | 0.00 | 0.89                         | 0.79                         |
| LV₁   | 0.87 | 0.85                         | 0.67                         |

Showing $R^2$ for target block LV₁ more than 87%. The proportion of variation characterizes share variations of a block, which reproduced latent variable this block. This characteristic for the all blocks far exceeds 50%, that positively characterizes the model. In the last column of a given indicator, which characterizes the dispersion excluded share (average particle dispersion indicators unit that explains the latent variable dispersion in the block that contains the error of measurement). Fashion AVE for the all blocks exceeds 50%, therefore, this criterion of the internal model is also considered satisfactory.

The fifth stage is the calculation of the single factor of quality conformity model data - GoF (Goodness-of-Fit [21]). Coefficient characterizes the quality as an internal model of the system, and external, and serves as an indicator of the reliability of the forecast model (predictive reliability model is considered to be high, if the coefficient of GoF > 70%).

Our model coefficient GoF=82%. Therefore, the constructed model can be used for forecasting. Finally, let’s analyze the final version of our model. The internal model can be written as the following equation:

$$LV₁ = 0.5143LV₂ + 0.6735LV₃ + 0.2903LV₄ + ε₁^{in}.$$ (6)

Estimates of latent variables are a system of equations:

$$
\begin{align*}
LV₁ &= 0.41x₁₁ + 0.24x₁₂ + 0.44x₁₄ \\
LV₂ &= 0.34x₂₁ + 0.42x₂₂ + 0.36(1 - x₂₃) \quad (1) \\
LV₃ &= 0.35(1 - x₃₁) + 0.30(1 - x₃₂) + 0.29x₃₃ + 0.23x₃₄ \quad (2) \\
LV₄ &= 0.38x₄₂
\end{align*}
$$ (7)

4 Conclusion

Two factors have the most significant direct impact on the level of stable development of the tourism business in the Odessa region (LV₁): LV₂ – level of social condition (comfort) and LV₃ - level of the environmental protection (ecological state of the region). The strength of their influence is 0.5143 and 0.6735 respectively. A weaker direct effect (with a strength of 0.2903) on the endogenous factor LV₁ is exerted by the exogenous factor LV₄ - condition of economics. Obviously, its influence is direct (through factors LV₂ and LV₃). According to
the results obtained, the level of social comfort (LV2) can be assessed using three factors: $x_{21}$ - total subsidies for the population; $x_{22}$ - the sum of state cost on the protection of public safety, health and other social services; $x_{23}$ - the proportion of the total number of unemployed persons to the economically active population (de-stimulating effect). The level of the environmental protection (LV3) can be assessed using 4 factors: $x_{31}$ - emissions of pollutants into atmospheric air and $x_{32}$ - wastes generation (de-stimulating effect); $x_{33}$ - state cost on the protection of the environment and $x_{34}$ - current expenditures on environmental.

On improving the state of the economy (factor LV4) is significantly influenced by $x_{42}$ - state spending on economic development. The level of stable development of tourism business (LV1) determined by the direct impact of three factors: $x_{11}$ - the number of tourists; $x_{12}$ - wage of employees in the service sector; $x_{14}$ - tax revenues from the travel industry. On the model you can count latent indexes for each year and create a stimulant to predict future values. Sustainability of development can be assessed by comparing the values of estimates for different periods. For example, if the estimation of the latent variables (LV2, LV3, LV4) current period previous period ratings are smaller, then the corresponding block is considered to be sustainable. Or for every variables you can define a baseline with which to conduct the comparison.
