UNPALATABILITY OF THE PYRROLIZIDINE ALKALOID-CONTAINING MoTH UTETHEISA ORNATRIX, AND ITS LARVA, TO WOLF SPIDERS\(^1\)

BY THOMAS EISNER AND MARIA EISNER

INTRODUCTION

The moth Utetheisa ornatrix (family Arctiidae) derives protection from pyrrolizidine alkaloids. It sequesters the toxins from its larval foodplant, retains them into adulthood, and allocates a fraction to the eggs (Eisner and Meinwald 1987, Dussourd et al. 1988). Evidence has shown adults and eggs to be unpalatable to predators. Adults are set free by orb weaving spiders, which cut them from the webs (Eisner 1982, Eisner and Meinwald 1987), and eggs are rejected by coccinellid beetles (Dussourd et al. 1988). Adults and eggs from a laboratory culture free of pyrrolizidine alkaloid are accepted by these predators.

We here report experiments demonstrating that Utetheisa, as larvae and adults, are protected against wolf spiders. Our tests were done with Lycosa ceratiola in Florida, both in the laboratory and field, and made use of Utetheisa adults and larvae of three types: (a) laboratory-raised, alkaloid-containing; (b) laboratory-raised, alkaloid-free; and (c) field-collected.

MATERIALS AND METHODS

The spider tested, Lycosa ceratiola, is relatively abundant at night on the sandy fire lanes at the Archbold Biological Station, Lake Placid, Florida. We spotted them with head-lamps by their strong reflected eye shine (Kaston 1978).

For laboratory testing, spiders were taken into vials and transferred singly into plastic containers (17 cm diameter, 11 cm height; with shallow bottom layer of sand), within which they quickly

assumed normal quiescent stances. They were usually tested on the night of capture, or at the latest 3 days thereafter. Prior to testing they were given only water (cotton-plugged vial). Presentation of test items involved taking an *Utetheisa* adult or larva in forceps, and dropping it from just above the spider to directly in front of the spider's chelicers.

For field testing, items were drop-delivered in the same fashion, but to recipient spiders that were still in place, naturally positioned on the ground where they had been spotted in the night. Approaching them slowly to within close range while maintaining them in the beam of light could be done usually without startling them.

The *Utetheisa* from laboratory culture were raised on two types of diet: alkaloid-free diet, from which alkaloid-free *Utetheisa* were obtained, individuals henceforth referred to by the the prefix (-); and alkaloid-containing diet, from which (+) individuals were obtained. Details about the composition of these diets are given in previous papers (Conner et al. 1981, Dussourd et al. 1988). Suffice it to say that the first diet is based on pinto beans, which are free of pyrrolizidine alkaloid, and the second is supplemented with seeds of *Crotalaria spectabilis*, a major host plant of *Utetheisa*. *C. spectabilis* contains the pyrrolizidine alkaloid *monocrotaline*. Our (+) individuals could therefore be expected to have substantial systemic loads of this alkaloid. Indeed, analysis had shown (+) adults and midsize (+) larvae to contain, respectively, 630 ± 50 µg (N = 31) and 152 ± 25 µg (N = 15) monocrotaline per individual (x ± SEM) (adult data, B. Roach, unpublished; larval data, J. Kopecky, unpublished). We used full-grown, last-instar larvae in our tests, which doubtless contained alkaloid levels higher than those of midsize larvae.

The field-collected *Utetheisa* [herein designated as (F)*Utetheisa*] were captured in the environs of Lake Placid, Florida, in and around stands of *Crotalaria mucronata*, a second major hostplant of the moth. *C. mucronata* contains usaramine as its pyrrolizidine alkaloid, a compound closely similar to monocrotaline. *Utetheisa* adults associated with this foodplant are known to contain usaramine in substantial amounts [x = 540 ± 30 (SEM) µg usaramine/moth (N = 31); B. Roach, unpublished]. No comparable data are available for larvae from this plant, although the ones we tested were of medium to full size, and thus presumably
endowed with near equivalents or equivalents of adult usaramine loads. Seven of the ten field-collected larvae were taken from the plants while they were still in what we estimated was the 3rd instar. They were maintained on fresh leaves and seed-pods of \textit{C. mucronata} in the laboratory for several days and not tested until they achieved mature or nearly mature size.

Adult \textit{Utetheisa} and spiders were sexed, but for the laboratory tests only; larvae were never sexed. Each test involved presentation of one type of prey item to 10 separate spiders. No spiders were tested twice, nor were rejected \textit{Utetheisa} larvae or adults ever reused. In tests where sexes were noted, moths and spiders were paired in every sex combination. The specifications for the 10 tests, with regard to setting, prey item offered, and (where noted) male/female ratio of item and spider, were as follows:

1. \textit{Laboratory}: (+)moths (5/5) (spiders 5/5)
2. \textit{Field}: (+)moths
3. \textit{Laboratory}: (-)moths (5/5) (spiders 4/6)
4. \textit{Field}: (-)moths
5. \textit{Laboratory}: (F)moths (5/5) (spiders 5/5)
6. \textit{Laboratory}: (+)larvae (spiders 4/6)
7. \textit{Field}: (+)larvae
8. \textit{Laboratory}: (-)larvae (spiders 3/7)
9. \textit{Field}: (-)larvae
10. \textit{Laboratory}: (F)larvae (spiders 2/8)

\textbf{RESULTS}

The results, summarized in Figure 1, were clear cut. All alkaloid-containing \textit{Utetheisa} [(+)larvae and (+)adults from laboratory culture; (F)larvae and (F)adults from the field] were rejected by \textit{Lycosa}, while (-)controls, devoid of alkaloid, were eaten.

The observed behavior by spiders did not differ in the laboratory and field tests. (-)Larvae and adults were instantly seized by the spiders (Fig. 2), which bore upon them with the chelicers, and kept them in a persistent hold, sometimes literally enfolding them with the legs, until the venom took effect. Laboratory tests were intermittently monitored until completion of feeding. Prey offerings had been made in the evening, and it usually took the spiders overnight to consume the prey. Larvae were reduced to shrivelled
Figure 1. Acceptability of adults and larvae of *Utetheisa ornatrix* to the spider *Lycosa ceratiola*. The *Utetheisa* were of three types, two of which [(+), (F)] contained pyrrolizidine alkaloid. The tests are numbered on the x-axis, in accord with the listing in the text. Sample size is N = 10 prey items per test. Further details in text.

integumental remains, and adults to compacted pellets and detached wings.

The release time for the alkaloid-laden *Utetheisa* was variable (Fig. 1). Adults almost without exception were freed within the minute of capture. (F)Moths were released as quickly as (+)moths, indicating that wild *Utetheisa* were as chemically unacceptable to *Lycosa* as individuals that had acquired their alkaloid from our artificial diet. Adults all survived the encounters uninjured. Many took to the wing instantly upon release. Larvae were not as quickly released, but they too survived the tests in most cases (as was determined by checking them for locomotory impairment after 48 hr). But there were two exceptions. These were both (+)larvae, from field tests, that had been held by spiders for 75 and 390 sec respectively. They were moribund on the second day and dead after 48 hr. We speculate that they died from envenomization.

**DISCUSSION**

Pyrrolizidine alkaloids, already known to protect *Utetheisa* against other predators (Eisner 1982, Eisner and Meinwald 1987, Dussourd et al. 1988), evidently protect the insect also against *Lycosa ceratiola*. Our field-collected *Utetheisa* proved as unacceptable to the spider as their laboratory-raised counterparts, indicating that the slightly different pyrrolizidine alkaloids they contained, usaramine and monocrotaline, are closely matched in deterrent potency.

Survival was high on the part of rejected individuals. Adult moths survived without exception; larvae survived with only two exceptions. The alkaloid-free controls were all eaten.

It would obviously have been desirable to test directly for the deterrent of pyrrolizidine alkaloids, by adding the chemicals topically to edible items (for instance, mealworms), and seeing whether by doing so one could render such items distasteful to *Lycosa*. We did such tests in earlier work with the orb-weaving spider *Nephi1a clavipes*, and found that pyrrolizidine alkaloids are indeed chemically deterrent (Eisner and Meinwald 1987). We suspect, therefore, that the chemicals would also have proved deterrent to *L. ceratiola*. In fact, pyrrolizidine alkaloids might be deterrent to lycosids generally, and perhaps even to spiders as a group. On numerous occasions, while in Florida, we offered wild-
caught adult *Utetheisa* to lycosids in the field (by the same feeding technique used herein) only to find the moths invariably rejected. We doubtless encountered a number of different lycosids by such random testing. Moreover, we have data (albeit scant), that adults of *Utetheisa* are distasteful also to jumping spiders (*Phidippus audax*).

Lycosids are probably not major predators of *Utetheisa*, although they might encounter the insect at times. Lycosids forage primarily on the ground, but—as anyone who searches for the spiders at night by light may note—they do on occasion take up positions on the branchings of vegetation. It is when they venture into such habitat, and specifically onto *Crotalaria* plants, that they could potentially be a threat to *Utetheisa*. Of special importance might be the vulnerability of the *Utetheisa* larva when it crawls away from its host plant in search of a pupation site (Bogner and Eisner 1991). It is then, when by necessity traversing ground, that it might be most at risk from lycosids.

**SUMMARY**

The arctiid moth, *Utetheisa ornatrix*, sequesters toxic pyrrolizidine alkaloids from its larval food plants. Evidence is presented indicating that the alkaloids are the basis of unpalatability of this insect to a lycosid spider (*Lycosa ceratiola*). Larval and adult *Utetheisa* endowed with pyrrolizidine alkaloid are rejected by the spider, while controls free of alkaloid are invariably eaten.

**ACKNOWLEDGMENTS**

Study supported in part by grant AI02908 from NIH, and Hatch grant NYS 191402. The experiments were done at the Archbold Biological Station, Lake Placid, Florida. We are indebted to the staff of the Station for innumerable kindnesses. All spiders were returned to their sites of capture, as were most field-collected *Utetheisa* (larvae and adults).
