Accelerated Gradient Tracking over Time-varying Graphs for Decentralized Optimization

Huan Li 1 Zhouchen Lin 2

Abstract
Decentralized optimization over time-varying graphs has been increasingly common in modern machine learning with massive data stored on millions of mobile devices, such as in federated learning. This paper revisits the widely used accelerated gradient tracking and extends it to time-varying graphs. We prove that the practical single loop accelerated gradient tracking needs $O\left(\left(\frac{\gamma_1 - \sigma}{\gamma}\right)^2 \sqrt{\frac{L}{\epsilon}}\right)$ and $O\left(\left(\frac{\gamma_1}{\gamma}\right)^{1.5} \sqrt{\frac{L}{\mu}} \log \frac{1}{\epsilon}\right)$ iterations to reach an $\epsilon$-optimal solution over time-varying graphs when the problems are nonstrongly convex and strongly convex, respectively, where $\gamma$ and $\sigma$ are two common constants charactering the network connectivity, $L$ and $\mu$ are the smoothness and strong convexity constants, respectively, and one iteration corresponds to one gradient oracle call and one communication round. Our convergence rates improve significantly over the ones of $O\left(\frac{1}{\epsilon^{5/7}}\right)$ and $O\left(\frac{L^{5/7}}{\mu^{5/7}} \log \frac{1}{\epsilon}\right)$, respectively, which were proved in the original literature of accelerated gradient tracking only for static graphs, where $\frac{\gamma_1 - \sigma}{\gamma}$ equals $\frac{1}{1-\sigma}$ when the network is time-invariant. When combining with a multiple consensus subroutine, the dependence on the network connectivity constants can be further improved to $O(1)$ and $O\left(\frac{1}{\gamma - \sigma}\right)$ for the gradient oracle and communication round complexities, respectively. When the network is static, by employing the Chebyshev acceleration, our complexities exactly match the lower bounds without hiding any poly-logarithmic factor for both nonstrongly convex and strongly convex problems.

1. Introduction
Distributed optimization has emerged as a promising framework in machine learning motivated by large-scale data being produced or stored in a network of nodes. Due to the popularity of smartphones and their growing computational power, time-varying graphs are increasingly common in modern distributed optimization, where the communication links in the network may vary with time, and the devices may not be active all the time such that the network may be even unconnected at each time. A typical example is federated learning (Li et al., 2020b; Kairouz et al., 2021), which involves training a global statistical model from data stored on millions of mobile devices. The physical constraints on each device typically result in only a small fraction of the devices being active at once, and it is possible for an active device to drop out at a given time (Bonawitz et al., 2019). Although centralized network is the predominant topology in most machine learning systems, such as TensorFlow, decentralized network has been a potential alternative because it reduces the high communication cost on the central server (Lian et al., 2017). This motivates us to study decentralized optimization over time-varying graphs. In this paper, we consider the following convex optimization problem:

$$\min_{x \in \mathbb{R}^p} F(x) = \frac{1}{m} \sum_{i=1}^{m} f_{(i)}(x),$$  \hspace{1cm} (1)$$

where the local objective functions $f_{(i)}$ are distributed separately over a network of nodes. The network is mathematically represented as a sequence of time-varying graphs $\{G^0, G^1, \ldots\}$, and each graph instance $G^k$ consists of a fixed set of agents $\mathcal{V} = \{1, \ldots, m\}$ and a set of time-varying edges $\mathcal{E}^k$. Agents $i$ and $j$ can exchange information at time $k$ if and only if

\footnote{2State Key Lab of General AI, School of Intelligence Science and Technology, Peking University, Beijing, China (zlin@pku.edu.cn).}
A direct consequence of the smoothness and convexity assumptions is the following property (Nesterov, 2004):

\[
\frac{1}{2L} \|\nabla f(y) - \nabla f(x)\|^2 \leq f(y) - f(x) - \langle \nabla f(x), y - x \rangle \leq \frac{L}{2} \|y - x\|^2.
\]

1.1. Notations and Assumptions

Throughout this article, we denote \( x^{(i)} \) to be the local variable for agent \( i \). We use the subscript \( (i) \) to distinguish the \( i \)th element of vector \( x \). To write the algorithm in a compact form, we introduce the aggregate variable \( F \) with its aggregate gradient \( \nabla F(x) \) as

\[
f(x) = \sum_{i=1}^{m} f^{(i)}(x^{(i)}), \quad x = \left( \begin{array}{c} x^{(1)}^T \\
\vdots \\
x^{(m)}^T \end{array} \right), \quad \nabla f(x) = \left( \begin{array}{c} \nabla f^{(1)}(x^{(1)})^T \\
\vdots \\
\nabla f^{(m)}(x^{(m)})^T \end{array} \right).
\]

Denote \( x^{k} \) to be the value at iteration \( k \). For scalars, for example, \( \theta \), we use \( \theta^{k} \) instead of \( \theta^{k} \) to denote the value at iteration \( k \), while the latter represents its \( k \)th power. Specially, \( x^\top \) means the transpose of \( x \). We denote \( \| \cdot \| \) to be the Frobenius norm for matrices and the \( \ell_2 \) Euclidean norm for vectors uniformly, and \( \| \cdot \|_2 \) as the spectral norm of matrices. Denote \( I \) as the identity matrix and \( 1 \) as the column vector of \( m \) ones. Assume that problem (1) has a solution, and let \( x^* \) be any one of them. Define the average variable across all the local variables as

\[
\bar{x} = \frac{1}{m} \sum_{i=1}^{m} x^{(i)}, \quad \bar{y} = \frac{1}{m} \sum_{i=1}^{m} y^{(i)}, \quad \bar{z} = \frac{1}{m} \sum_{i=1}^{m} z^{(i)}, \quad \bar{s} = \frac{1}{m} \sum_{i=1}^{m} s^{(i)},
\]

where \( x, y, z, \) and \( s \) will be used later in the development of the algorithm. Define operator \( \Pi = I - \frac{1}{m} 1^\top 1 \) to measure the consensus violation such that

\[
\Pi x = \left( \begin{array}{c} x^{(1)}^\top - \bar{x}^\top \\
\vdots \\
x^{(m)}^\top - \bar{x}^\top \end{array} \right).
\]

We make the following assumptions for each local objective function in problem (1).

**Assumption 1**

1. Each \( f^{(i)}(x) \) is \( \mu \)-strongly convex: \( f^{(i)}(y) \geq f^{(i)}(x) + \langle \nabla f^{(i)}(x), y - x \rangle + \frac{\mu}{2} \|y - x\|^2 \). Especially, we allow \( \mu \) to be zero throughout this paper, and in this case we say \( f^{(i)}(x) \) is convex.

2. Each \( f^{(i)}(x) \) is \( L \)-smooth, that is, \( f^{(i)}(x) \) is differentiable and its gradient is \( L \)-Lipschitz continuous: \( \|\nabla f^{(i)}(y) - \nabla f^{(i)}(x)\| \leq L \|y - x\| \).

A direct consequence of the smoothness and convexity assumptions is the following property (Nesterov, 2004):

\[
\frac{1}{2L} \|\nabla f(y) - \nabla f(x)\|^2 \leq f(y) - f(x) - \langle \nabla f(x), y - x \rangle \leq \frac{L}{2} \|y - x\|^2.
\]
Assumption 2

1. (Decentralized property) $W_{i,j} > 0$ if and only if $(i, j) \in \mathcal{E}$ or $i = j$. Otherwise, $W_{i,j} = 0$.

2. (Double stochasticity) $W 1 = 1$ and $1^T W = 1^T$.

Note that we do not assume that $W$ is symmetric. If the network is connected, Assumption 2 implies that the second largest singular value $\sigma$ of $W$ is less than 1 (its largest one equals 1), that is, $\sigma = \|W - \frac{1}{m} 11^T\|_2 < 1$. Moreover, we have the following classical consensus contraction:

$$\|\Pi W x\| = \left\| \left(W - \frac{1}{m} 11^T\right)x\right\| = \left\| \left(W - \frac{1}{m} 11^T\right) \left(I - \frac{1}{m} 11^T\right)x\right\| \leq \sigma \|\Pi x\|. \quad (6)$$

We often use $\frac{1}{1-\sigma}$ as the condition number of the communication network.

When the network is time-varying, each graph instance $\mathcal{G}^k$ associates with a gossip matrix $W^k$. Denote

$$W^{k,\gamma} = W^k W^{k-1} \cdots W^{k-\gamma+1}, \quad \text{for any } k \geq \gamma - 1, \quad (7)$$

$W^{k,0} = I$, and we follow (Nedić et al., 2017) to make the following standard assumptions for the sequence of gossip matrices $\{W^k\}_{k=0}^\infty$.

Assumption 3

1. (Decentralized property) $W^k_{i,j} > 0$ if and only if $(i, j) \in \mathcal{E}^k$ or $i = j$. Otherwise, $W^k_{i,j} = 0$.

2. (Double stochasticity) $W^k 1 = 1$ and $1^T W^k = 1^T$.

3. (Joint spectrum property) There exists a constant integer $\gamma$ such that

$$\sigma_\gamma < 1, \quad \text{where} \quad \sigma_\gamma = \sup_{k \geq \gamma+1} \left\| W^{k,\gamma} - \frac{1}{m} 11^T \right\|_2. \quad (8)$$

Assumption 3 is weaker than the assumption that every graph $\mathcal{G}^k$ is connected. A typical example of the gossip matrix satisfying Assumption 3 is the Metropolis weight over $\gamma$-connected graphs. The former is defined as

$$W^k_{ij} = \begin{cases} 1/(1 + \max\{d_i^k, d_j^k\}), & \text{if } (i, j) \in \mathcal{E}^k, \\ 0, & \text{if } (i, j) \notin \mathcal{E}^k \text{ and } i \neq j, \\ 1 - \sum_{l \in N_{(i)}^k} W^k_{lj}, & \text{if } i = j, \end{cases} \quad (8)$$

where $N_{(i)}^k$ is the set of neighbors of agent $i$ at time $k$, and $d_i^k = |N_{(i)}^k|$ is the degree. The $\gamma$-connected graph sequence is defined as follows (Nedić et al., 2017).

Definition 1 The time-varying undirected graph sequence $\{\mathcal{V}, \mathcal{E}^k\}_{k=0}^\infty$ is $\gamma$-connected if there exists some positive integer $\gamma$ such that the union of these $\gamma$ consecutive undirected graphs $\{\mathcal{V}, \mathcal{E}_{r=0}^{k+\gamma-1}\}$ is connected for all $k = 0, 1, \ldots$.

When Assumption 3 holds, we have the following $\gamma$-step consensus contraction:

$$\|\Pi W^{k,\gamma} x\| \leq \sigma_\gamma \|\Pi x\|, \quad \text{for any } k \geq \gamma - 1. \quad (9)$$

When the algorithm proceeds less than $\gamma$ steps, we only have

$$\|\Pi W^{k,t} x\| \leq \|\Pi x\|, \quad \text{for any } 0 \leq t < \gamma \text{ and } k \geq t - 1. \quad (10)$$

In decentralized optimization, people often use communication round complexity and gradient oracle complexity to measure the convergence speed. The former means the number of communication rounds to reach an $\epsilon$-optimal solution with $F(x) - F(x^*) \leq \epsilon$, while the latter means the number of gradient oracle calls. In one communication round, all the agents can receive $O(1)$ vectors, such as $x_{(i)}^k$, from each of its neighbors in parallel, which can be represented as $W^k x^k$ mathematically. In one gradient oracle call, all the agents call the oracle to compute their local gradients $\nabla f_{(i)}(x_{(i)}^k)$ in parallel.
1.2. Literature Review

In this section, we briefly review the decentralized algorithms over static graphs and time-varying graphs, mainly focusing on the accelerated methods. We emphasize gradient tracking (Nedić et al., 2017) and its acceleration (Qu & Li, 2020), which are mostly relevant for our work. Tables 1 and 2 sum up the complexity comparisons of the state-of-the-art methods.

1.2.1. Decentralized Optimization over Static Graphs

Decentralized optimization has been studied for a long time (Bertsekas, 1983; Tsitsiklis et al., 1986). The representative decentralized algorithms include distributed gradient/subgradient descent (DGD) (Nedić & Ozdaglar, 2009; Nedić, 2011; Ram et al., 2010; Yuan et al., 2016), EXTRA (Shi et al., 2015b,a), gradient tracking (Nedić et al., 2017; Qu & Li, 2018; Xu et al., 2015; Xin et al., 2018), NIDS (Li et al., 2019), as well as the dual based methods, such as dual ascent (Terelius et al., 2011), dual averaging (Duchi et al., 2012), ADMM (Wei & Ozdaglar, 2013; Iutzeler et al., 2016; Makhdoumi & Ozdaglar, 2017), and the primal-dual method (Lan et al., 2020; Scaman et al., 2018; Hong et al., 2017; Jakovetić, 2019). Among these methods, gradient tracking has the $O\left(\frac{L}{\mu (1-\sigma)^2} \log \frac{1}{\epsilon}\right)$ complexity for strongly convex problems and the $O\left(\frac{L}{\mu (1-\sigma)^2} \log \frac{1}{\epsilon}\right)$ complexities for nonstrongly convex ones. Recently, accelerated decentralized methods have gained significant attention due to their provable faster convergence rates.

Accelerated Methods for Strongly Convex and Smooth Decentralized Optimization. The accelerated methods which can be applied to this scenario include the accelerated distributed Nesterov gradient descent (Acc-DNGD) (Qu & Li, 2020), the robust distributed accelerated stochastic gradient method (Fallah et al., 2022), the multi-step dual accelerated method (Scaman et al., 2017; 2019), accelerated penalty method (APM) (Li et al., 2020a; Dvinskikh & Gasnikov, 2021), the multi-consensus decentralized accelerated gradient descent (Mudag) (Ye et al., 2023; 2020), accelerated EXTRA (Li & Lin, 2020; Li et al., 2022), the decentralized accelerated augmented Lagrangian method (Arjevani et al., 2020), and the accelerated proximal alternating predictor-corrector method (APAPC) (Kovalev et al., 2020). Scaman et al. (2017; 2019) proved the $\Omega\left(\frac{L}{\mu (1-\sigma)^2} \log \frac{1}{\epsilon}\right)$ and $\Omega\left(\frac{L}{\mu} \log \frac{1}{\epsilon}\right)$ lower bounds for communication rounds and gradient oracle calls, respectively. To the best of our knowledge, APAPC combined with the Chebyshev acceleration (CA) (Arioli & Scott, 2014) is the first to exactly achieve these lower bounds without hiding any poly-logarithmic factor. Although gradient tracking has been widely used in practice, its accelerated variant, Acc-DNGD, only has the $O\left(\frac{L}{\mu (1-\sigma)^2} \log \frac{1}{\epsilon}\right)$ communication round and gradient oracle complexities (Qu & Li, 2020).

Accelerated Methods for Nonstrongly Convex and Smooth Decentralized Optimization. The accelerated methods for this scenario are much scarcer. Examples include the distributed Nesterov gradient with consensus (Jakovetić et al., 2014a), Acc-DNGD (Qu & Li, 2020), APM (Li et al., 2020a; Dvinskikh & Gasnikov, 2021), accelerated EXTRA (Li & Lin, 2020), and the accelerated dual ascent (Uribe et al., 2021), where the last one adds a small regularizer to translate the problem to a strongly convex and smooth one. Scaman et al. (2019) proved the $\Omega\left(\frac{L}{\mu (1-\sigma)^2}\right)$ communication round complexity lower bound and the $\Omega\left(\frac{L}{\mu}\right)$ gradient oracle complexity lower bound. To the best of our knowledge, there is no method matching these lower bounds exactly without hiding any poly-logarithmic factor. APM comes close to this target, but with an additional $O\left(\log \frac{1}{\epsilon}\right)$ factor in the communication round complexity. Acc-DNGD, acceleration of gradient tracking, only has the $O\left(\frac{L}{\mu (1-\sigma)^2}\right)$ complexities of communication rounds and gradient oracles, originally proved in (Qu & Li, 2020). Note that the dependence on $1-\sigma$, a small constant charactering the network connectivity, was not explicitly given in (Qu & Li, 2020). Xu et al. (2020) proposed an accelerated primal dual method, however, their complexities remain $O\left(\frac{1}{\epsilon}\right)$.

1.2.2. Decentralized Optimization over Time-varying Graphs

We review the decentralized algorithms over time-varying graphs in two scenarios. In the first scenario, the network may not be connected at every time, but it is assumed to be $\gamma$-connected. In the second scenario, the network is assumed to be connected at every time.

Not Connected at Every Time but $\gamma$-connected. In this scenario, DiGing (that is, gradient tracking over time-varying graphs) (Nedić et al., 2017), PANDA (Maros & Jalden, 2018; 2019), the time-varying AB/push-pull method (Saadatiakia et al., 2020), the decentralized stochastic gradient descent (SGD) (Koloskova et al., 2020), and the push-sum based methods (Nedić & Olshevsky, 2016; 2015; Nedić et al., 2017) are the representative non-accelerated methods over time-varying graphs for convex problems, as well as NEXT (Lorenzo & Scutari, 2016) and SONATA (Scutari & Sun, 2019) for nonconvex problems. When combing with Nesterov’s acceleration, to the best of our knowledge, the decentralized accelerated gradient
Compare the state-of-the-art complexities of decentralized methods over static graphs, as well as those of gradient tracking and its accelerated variant Acc-DNGD. Double loop means the method needs to call a subroutine with multiple steps at each iteration, such as the Chebyshev acceleration, the multiple consensus, the gradient evaluation of Fenchel conjugate, or the minimization of a subproblem.

Connected at Every Time. In this scenario, the literature is rich and many distributed methods originally designed over static graphs, such as Acc-DNGD, can be directly used. Kovalev et al. (2021b; a) proposed a dual based method named ADOM and its primal-only extension ADOM+, where the latter has the state-of-the-art $O\left(\frac{L}{\sqrt{\mu(1-\sigma)}} \log \frac{1}{\epsilon} \right)$ communication round complexity and the $O\left(\sqrt{\frac{L}{\mu}} \log \frac{1}{\epsilon} \right)$ gradient oracle complexity for strongly convex and smooth problems. Kovalev et al. (2021a) also established the lower bounds showing that their ADOM+ is optimal. Rogozin et al. (2020) gave the complexity of $O\left(\sqrt{\frac{L}{\mu(1-\sigma)}} \log \frac{1}{\epsilon} \right)$ under a stronger assumption that the network changes slowly in the sense that the number of network.

| Methods | gradient oracle complexity | communication round complexity | single or double loop |
|---------|---------------------------|-------------------------------|----------------------|
| Nonstrongly convex and smooth functions | | | |
| Gradient tracking (Qu & Li, 2018) | $O\left(\frac{L}{\sqrt{1-\sigma}}\right)$ | $O\left(\frac{L}{\sqrt{1-\sigma}}\right)$ | single |
| Acc-DNGD (Qu & Li, 2020) | $O\left(\frac{L}{\sqrt{1-\sigma}}\right)$ | $O\left(\frac{L}{\sqrt{1-\sigma}}\right)$ | single |
| APM (Li et al., 2020a) | $O\left(\sqrt{\frac{L}{\mu}}\right)$ | $O\left(\sqrt{\frac{L}{\mu}} \log \frac{1}{\epsilon} \right)$ | double |
| Acc-EXTRA (Dvinskikh & Gasnikov, 2021) | $O\left(\sqrt{\frac{L}{\mu}} \log \frac{1}{\epsilon} \right)$ | $O\left(\sqrt{\frac{L}{\mu}} \log \frac{1}{\epsilon} \right)$ | double |
| Lower bounds (Scaman et al., 2019) | $O\left(\sqrt{\frac{L}{\mu}}\right)$ | $O\left(\sqrt{\frac{L}{\mu(1-\sigma)}}\right)$ | / |

| Strongly convex and smooth functions | | | |
| Gradient tracking (Alghunaim et al., 2021) | $O\left(\left(\frac{L}{\mu} + \frac{1}{(1-\sigma)^{\frac{5}{2}}}\right) \log \frac{1}{\epsilon} \right)$ | $O\left(\left(\frac{L}{\mu} + \frac{1}{(1-\sigma)^{\frac{5}{2}}}\right) \log \frac{1}{\epsilon} \right)$ | single |
| Acc-DNGD (Qu & Li, 2020) | $O\left(\left(\frac{L}{\mu}\right)^{\frac{5}{2}} + \frac{1}{(1-\sigma)^{\frac{5}{2}}} \log \frac{1}{\epsilon} \right)$ | $O\left(\left(\frac{L}{\mu}\right)^{\frac{5}{2}} + \frac{1}{(1-\sigma)^{\frac{5}{2}}} \log \frac{1}{\epsilon} \right)$ | single |
| APM (Kovalev et al., 2020) | $O\left(\sqrt{\frac{L}{\mu}} \log \frac{1}{\epsilon} \right)$ | $O\left(\sqrt{\frac{L}{\mu}} \log \frac{1}{\epsilon} \right)$ | double |
| Our results for Acc-GT | $O\left(\sqrt{\frac{L}{\mu(1-\sigma)^{\frac{5}{2}}} \log \frac{1}{\epsilon} \right)$ | $O\left(\sqrt{\frac{L}{\mu(1-\sigma)^{\frac{5}{2}}} \log \frac{1}{\epsilon} \right)$ | single |
| Our results for Acc-GT+CA | $O\left(\sqrt{\frac{L}{\mu(1-\sigma)^{\frac{5}{2}}} \log \frac{1}{\epsilon} \right)$ | $O\left(\sqrt{\frac{L}{\mu(1-\sigma)^{\frac{5}{2}}} \log \frac{1}{\epsilon} \right)$ | double |
| Lower bounds (Scaman et al., 2019) | $O\left(\sqrt{\frac{L}{\mu}} \log \frac{1}{\epsilon} \right)$ | $O\left(\sqrt{\frac{L}{\mu(1-\sigma)^{\frac{5}{2}}} \log \frac{1}{\epsilon} \right)$ | / |
Table 2. Comparisons among the state-of-the-art complexities of decentralized methods over time-varying graphs. We only compare with the methods working over γ-connected graphs.

| Methods | Nonstrongly convex and smooth functions | Strongly convex and smooth functions |
|---------|----------------------------------------|-------------------------------------|
| DGD\(^1\) (Koloskova et al., 2020) | \(O \left( \frac{\gamma^2 \sqrt{T}}{(1-\sigma^2)^2} \frac{L}{\mu} \log \frac{1}{\delta} \right)\) | \(O \left( \frac{\gamma^2 \sqrt{T}}{(1-\sigma^2)^2} \frac{L}{\mu} \log \frac{1}{\delta} \right)\) |
| APM (Li et al., 2020a) | \(O \left( \frac{\gamma T}{(1-\sigma^2)^2} \sqrt{\frac{L}{\mu}} \right)\) | \(O \left( \frac{\gamma T}{(1-\sigma^2)^2} \sqrt{\frac{L}{\mu}} \right)\) |
| Our results for Acc-GT | \(O \left( \frac{\gamma^2}{(1-\sigma^2)^2} \frac{L}{\mu} \log \frac{1}{\delta} \right)\) | \(O \left( \frac{\gamma^2}{(1-\sigma^2)^2} \frac{L}{\mu} \log \frac{1}{\delta} \right)\) |
| Our results for Acc-GT+ multiple consensus | \(O \left( \frac{\gamma}{(1-\sigma^2)^2} \frac{L}{\mu} \log \frac{1}{\delta} \right)\) | \(O \left( \frac{\gamma}{(1-\sigma^2)^2} \frac{L}{\mu} \log \frac{1}{\delta} \right)\) |

\(^1\)The method in (Koloskova et al., 2020) was designed for stochastic decentralized optimization. We recover the complexities for deterministic optimization by setting the variance of the stochastic gradient to be zero. On the other hand, \(\xi = \frac{1}{m} \sum_{i=1}^{m} \| \nabla f_i(x^*) \|^2\).
the same as that of DAGD-C.

(c) To the best of our knowledge, this is the first time that the communication round upper bound with the optimal dependence on the precision \( \epsilon \) and condition number \( L/\mu \) is given for both nonstrongly convex and strongly convex problems. More importantly, they are established for a practical single loop algorithm.

2. For static graphs as a special case, our contributions include:

(a) When the local objective functions are nonstrongly convex and smooth, we prove the \( O\left( \frac{1}{\sqrt{1} - \sigma^2} \sqrt{\frac{L}{\mu}} \right) \) complexities of communication rounds and gradient oracles for the practical single loop Acc-GT, which significantly improve over the existing \( O\left( \frac{1}{\sqrt{\epsilon}} \right) \) ones originally proved in (Qu & Li, 2020). When combing with the Chebyshev acceleration, we can improve the complexities to \( O\left( \sqrt{\frac{L}{\mu(1-\sigma^2)}} \right) \) for communication rounds and \( O\left( \frac{L}{\sigma} \right) \) for gradient oracles, which exactly match the complexity lower bounds. As far as we know, we are the first to establish the optimal upper bounds for nonstrongly convex and smooth problems, which exactly match the corresponding lower bounds without hiding any poly-logarithmic factor.

(b) When the local objective functions are strongly convex and smooth, we prove the \( O\left( \frac{L}{\mu(1-\sigma^2)} \log \frac{1}{\epsilon} \right) \) communication round and gradient oracle complexities for the practical single loop Acc-GT, which improves over the existing \( O\left( \frac{L}{\mu(1-\sigma^2)} \log \frac{1}{\epsilon} \right) \) ones originally given in (Qu & Li, 2020). When combing with the Chebyshev acceleration, the complexities can be further improved to match the corresponding lower bounds and existing optimal upper bounds.

2. Accelerated Gradient Tracking over Time-varying Graphs

We first review the gradient tracking and its accelerated variant, where the latter was only designed over static graphs, and then give our extensions of the accelerated gradient tracking to time-varying graphs with sharper complexities.

2.1. Review of Gradient Tracking and Its Acceleration

Gradient tracking (Nedić et al., 2017; Qu & Li, 2018; Xu et al., 2015; Xin et al., 2018) keeps an auxiliary variable \( s^{k}_{(i)} \) at each iteration for each agent \( i \) to track the average of the gradients \( \nabla f_{(j)}(x^{k}_{(j)}) \) for all \( j = 1, ..., m \), such that if \( x^{k}_{(i)} \) converges to some point \( x^\infty \), \( s^{k}_{(i)} \) converges to \( \frac{1}{m} \sum_{i=1}^{m} \nabla f_{(i)}(x^\infty) \). The auxiliary variable is updated recursively as follows:

\[
s^{k}_{(i)} = \sum_{j \in N(i)} W_{ij} s^{k-1}_{(j)} + \nabla f_{(i)}(x^{k}_{(i)}) - \nabla f_{(i)}(x^{k-1}_{(i)}),
\]

and each agent uses this auxiliary variable as the descent direction in the general distributed gradient descent framework:

\[
x^{k+1}_{(i)} = \sum_{j \in N(i)} W_{ij} x^{k}_{(j)} - \alpha s^{k}_{(i)},
\]

where \( \alpha \) is the step size. Writing gradient tracking in the compact form, it reads as follows:

\[
s^{k} = W s^{k-1} + \nabla f(x^{k}) - \nabla f(x^{k-1}),
\]

\[
x^{k+1} = W x^{k} - \alpha s^{k},
\]

Gradient tracking can be used over both static graphs and time-varying graphs (Nedić et al., 2017).

To further accelerate gradient tracking, Qu & Li (2020) employed Nesterov’s acceleration technique (Nesterov, 2004) and proposed the following accelerated distributed Nesterov gradient descent for nonstrongly convex problems:

\[
y^{k} = \theta_{k} z^{k} + (1 - \theta_{k}) x^{k}, \tag{12a}
\]

\[
s^{k} = W s^{k-1} + \nabla f(y^{k}) - \nabla f(y^{k-1}), \tag{12b}
\]

\[
x^{k+1} = W y^{k} - \alpha s^{k}, \tag{12c}
\]

\[
z^{k+1} = W z^{k} - \frac{\alpha}{\theta_{k}} s^{k}. \tag{12d}
\]
We follow the proof idea in (Jakovetić et al., 2014a; Qu & Li, 2020) to rewrite the distributed algorithm in the form of inexact gradient tracking. When strong convexity is assumed, Qu & Li (2020) fixed \( \theta \) such that
\[
\theta_0 = \sum_{i \in N(i)} W_{ij} x_{ij}^0.
\]
We initialize \( x_{ij} = x_{int} \), \( s_{ij}^0 = \nabla f(i)(y_{ij}^0) \), \( z_{ij}^0 = \sum_{j \in N(i)} W_{ij} x_{ij}^0 - \frac{\alpha}{\mu_0 + \mu s_{ij}^0} \), and \( x_{ij}^1 = \theta_0 z_{ij}^1 + (1 - \theta_0) \sum_{j \in N(i)} W_{ij} x_{ij}^0 \).

For \( k = 1, 2, \ldots \) do
\[
y_{ij}^k = \theta_k z_{ij}^k + (1 - \theta_k) x_{ij}^k,
\]
\[
s_{ij}^k = \sum_{j \in N(i)} W_{ij} s_{ij}^{k-1} + \nabla f(i)(y_{ij}^k) - \nabla f(i)(y_{ij}^{k-1}),
\]
\[
z_{ij}^{k+1} = \frac{1}{1 + \frac{\alpha x_{ij}}{s_{ij}}} \left( \sum_{j \in N(i)} W_{ij} \frac{\mu x_{ij} y_{ij}^{k} + z_{ij}^k}{\theta_k} - \frac{\alpha}{\theta_k} s_{ij}^k \right),
\]
\[
x_{ij}^{k+1} = \theta_k z_{ij}^{k+1} + (1 - \theta_k) \sum_{j \in N(i)} W_{ij} x_{ij}^k,
\]
end for

It can be checked that step (12c) is equivalent to the following one:
\[
x^{k+1} = \theta_k z^{k+1} + (1 - \theta_k) W x^k.
\]

When strong convexity is assumed, Qu & Li (2020) fixed \( \theta_k \) at each iteration and replaced steps (12a) and (12d) by the following two steps:
\[
y^k = x^k + \frac{\theta z^k}{1 + \theta}, \quad z^{k+1} = (1 - \theta) W z^k + \theta W y^k - \frac{\alpha s^k}{\theta}.
\]

The main idea behind the development of the above accelerated algorithms is to relate it to the inexact accelerated gradient descent (Devolder et al., 2014) by taking average of the local variables over all \( i = 1, \ldots, m \). See Section 3.1 for the details. Tables 1 and 2 list the complexities of gradient tracking and its accelerated variant.

### 2.2. Extension of Accelerated Gradient Tracking to Time-varying Graphs

In this paper, we study the following accelerated gradient tracking with time-varying gossip matrices:
\[
y^k = \theta_k z^k + (1 - \theta_k) x^k, \quad (13a)
\]
\[
s^k = W^k s^{k-1} + \nabla f(y^k) - \nabla f(y^{k-1}), \quad (13b)
\]
\[
z^{k+1} = \frac{1}{1 + \frac{\alpha x_{ij}}{s_{ij}}} \left( W^k \frac{\mu x_{ij} y^k + z^k}{\theta_k} - \frac{\alpha}{\theta_k} s^k \right), \quad (13c)
\]
\[
x^{k+1} = \theta_k z^{k+1} + (1 - \theta_k) W^k x^k. \quad (13d)
\]

where we initialize \( x^0 \) such that \( \Pi x^0 = 0 \). We give the specific descriptions of the method in Algorithm 1 in a distributed way.

Step (13b) is the standard gradient tracking, while steps (13a), (13c), and (13d) come from Nesterov’s classical accelerated gradient descent (Nesterov, 2004), except that one round of consensus communication is performed by multiplying the aggregate variables with a gossip matrix. We see that algorithm (13a)-(13d) is equivalent to (12a)-(12d) when the gossip matrix is fixed and \( \mu = 0 \). However, when \( \mu > 0 \), it is not equivalent to the method proposed in (Qu & Li, 2020). In fact, Nesterov’s accelerated gradient methods have several variants, and we choose the one in the form of (13a)-(13d) due to its simple convergence proof.

We follow the proof idea in (Jakovetić et al., 2014a; Qu & Li, 2020) to rewrite the distributed algorithm in the form of inexact accelerated gradient descent. However, we use a different proof framework from (Qu & Li, 2020) with much simpler proofs, and give sharper complexities. See Remark 9 for the differences and the reasons of the convergence rates improvement. On the other hand, for time-varying graphs, unlike the classical analysis relying on the small gain theorem (Nedić et al., 2017), we construct a different way to bound the consensus errors such that the proof framework over static graphs can be
extended to time-varying graphs. See the proof of Lemma 7 and the remark following it. Our proof technique may shed new light to decentralized optimization over time-varying graphs, and gives an alternative to the small gain theorem. There are two advantages of our proof technique: it can be embedded into many algorithm frameworks from the perspective of error analysis, and it can be applied to both strongly convex and nonstrongly convex problems, while the small gain theorem only applies to strongly convex ones.

Our main technical results concerning the convergence rates of the accelerated gradient tracking are summarized in the following two theorems for nonstrongly convex and strongly convex problems, respectively.

**Theorem 1** Suppose that Assumption 1 holds with \( \mu = 0 \) and Assumption 3 holds for the sequence \( \{W^k\}_{k=0}^\gamma \). Let the sequence \( \{\theta_k\}_{k=0}^\gamma \) satisfy \( \frac{1 - \theta_k}{\sigma_k^2} = \frac{1}{\sigma_{k-1}^2} \) with \( \theta_0 = 1 \), let \( \alpha \leq \frac{(1 - \sigma_\gamma)^3}{24L\gamma} \). Then for algorithm (13a)-(13d), we have for any \( T \geq 1 \),

\[
F(\pi^{T\gamma+1}) - F(x^*) \leq \frac{2C}{\alpha(T\gamma + 1)^2},
\]

and

\[
\frac{1}{m} \||\Pi x^{T\gamma}||^2 \leq \frac{9C}{\alpha L(T\gamma + 1)^2};
\]

where \( C = \|\pi^0 - x^*\|^2 + \frac{\alpha (1 - \sigma_\gamma)}{180L\gamma} \max_{r=0,...,\gamma} ||\Pi s^r||^2 \).

**Theorem 2** Suppose that Assumption 1 holds with \( \mu > 0 \) and Assumption 3 holds for the sequences \( \{W^k\}_{k=0}^\gamma \). Let \( \alpha \leq \frac{(1 - \sigma_\gamma)^3}{24L\gamma} \) and \( \theta_k \equiv 0 = \frac{\sqrt{m\sigma}}{2} \). Then for algorithm (13a)-(13d), we have for any \( T \geq 1 \),

\[
F(\pi^{T\gamma+1}) - F(x^*) + \left( \frac{\theta^2}{2\alpha} + \frac{\mu\theta}{2} \right) \|\pi^{T\gamma+1} - x^*\|^2 \leq (1 - \theta)^{T\gamma+1} C,
\]

and

\[
\frac{1}{m} \||\Pi x^{T\gamma}||^2 \leq (1 - \theta)^{T\gamma+1} \frac{4C}{L},
\]

where \( C = F(\pi^0) - F(x^*) + \left( \frac{\theta^2}{2\alpha} + \frac{\mu\theta}{2} \right) \|\pi^0 - x^*\|^2 + \frac{1 - \sigma_\gamma}{49mL\gamma(1 - \theta)} M^\gamma_\gamma + \frac{1459L\gamma^3}{m(1 - \theta)(1 - \sigma_\gamma)} M^\gamma_\gamma + \frac{6.6L\gamma^2}{m(1 - \theta)(1 - \sigma_\gamma)} M^\gamma_\gamma, M = \max_{r=1,...,\gamma} ||\Pi s^r||^2 \), and similarly for \( M^\gamma_\gamma \) and \( M^\gamma_\gamma \).

When the local objectives are nonstrongly convex, we see from Theorem 1 that algorithm (13a)-(13d) needs \( \mathcal{O}\left(\frac{(\frac{\gamma}{1 - \sigma_\gamma})^2 \sqrt{\frac{L\mu}{\epsilon}}}{\epsilon}\right) \) communication rounds and gradient oracle calls to find an \( \epsilon \)-optimal averaged solution (see Remark 11). When strong convexity is assumed, we see from Theorem 2 that both the communication round and gradient oracle complexities are \( \mathcal{O}\left(\frac{(\frac{\gamma}{1 - \sigma_\gamma})^{1.5} \sqrt{\frac{L}{\mu} \log \frac{1}{\epsilon}}}{\epsilon}\right) \). Our complexities have the optimal dependence on the precision \( \epsilon \) and the condition number \( L/\mu \), matching that of the classical centralized accelerated gradient method. As illustrated in Table 2, our communication round complexities improve over the state-of-the-art APM (Li et al., 2020a) and DAGD-C (Rogozin et al., 2021b) on the dependence of \( \epsilon \) since they have an additional \( \mathcal{O}\left(\frac{\log \frac{1}{\epsilon}}{\epsilon}\right) \) factor. However, our dependence on \( \frac{1}{1 - \sigma_\gamma} \) is not state-of-the-art. We will improve it in Section 2.4.

Remark 1 In order to establish the proof, we use very small stepizes with huge constants in the theorems, which is impractical. We suggest to tune the best stepsize in practice, rather than the ones used in the theorems.

Remark 2 We measure the convergence rates at the averaged solution, which can be obtained by an additional consensus average routine \( u^{t+1} = W^t u^t \) initialized at \( u^0 = x^{T\gamma+1} \), and \( \mathcal{O}\left(\frac{\gamma}{1 - \sigma_\gamma} \log \frac{1}{\epsilon}\right) \) rounds of communications are enough. So the total complexities are \( \mathcal{O}\left(\frac{(\frac{\gamma}{1 - \sigma_\gamma})^2 \sqrt{\frac{L\mu}{\epsilon}}}{\epsilon}\right) + \mathcal{O}\left(\frac{\gamma}{1 - \sigma_\gamma} \log \frac{1}{\epsilon}\right) \) and \( \mathcal{O}\left(\frac{(\frac{\gamma}{1 - \sigma_\gamma})^{1.5} \sqrt{\frac{L}{\mu} \log \frac{1}{\epsilon}}}{\epsilon}\right) + \mathcal{O}\left(\frac{\gamma}{1 - \sigma_\gamma} \log \frac{1}{\epsilon}\right) \) for nonstrongly convex and strongly convex problems, respectively, and they are dominated by the first parts.
Remark 3  For nonstrongly convex problems, we can also prove the convergence rate measured at the point $x_{(i)}^{T\gamma+1}$ for any $i$:

$$F(x_{(i)}^{T\gamma+1}) - F(x^*) \leq \frac{2C}{\alpha(T\gamma + 1)^2} \max \left\{ \sqrt{m}(1 - \sigma) \theta_0, 8m \right\}. $$

However, the complexities increase to $O(\max\{\sqrt{m}, \sqrt{m}(\frac{1}{1 - \sigma})^{1.5}\} \sqrt{\frac{L}{\epsilon}})$. For strongly convex problems, the complexities stay the same no matter measured at $\pi^{T\gamma+1}$ or $x_{(i)}^{T\gamma+1}$ because the additional terms, such as $\max\{\sqrt{m}, \sqrt{m}(\frac{1}{1 - \sigma})^{1.5}\}$ in the nonstrongly convex case, appear in the constant $C'$ in $O(\frac{\sqrt{L}}{\mu \log C'})$.

Remark 4  In Theorems 1 and 2, we measure the convergence rates at the $(T\gamma + 1)$th iteration for simplicity. In fact, the same rates hold for any $K = T\gamma + r$ with $1 \leq r \leq \gamma$ by regarding the $(r - 1)$th iteration as the virtual initialization, which only influences the constant $C$ in Theorems 1 and 2. In addition, since $\theta_{r-1} < 1$, the constant $C$ in Theorem 1 contains an additional term $\frac{\alpha(1 - \theta_{r-1})}{\theta_{r-1}}(F(x^{r-1}) - F(x^*))$.

Remark 5  Due to the physical constraints such as the battery dies, the device shuts down, or the WiFi network is unavailable, the agents may not be active all the time. Most literature let the agents wait and use the old iterates when rejoining the network. Alternatively, we can formulate this case by local updates (Stich, 2019; Koloskova et al., 2020) and use our analysis framework to ensure the convergence. Mathematically, letting $W_{ij}^k = 1$ and $W_{ij}^k = 0$ for all $j \neq i$ and $k = t + 1, t + 2, ..., t'$, which means that agent $i$ drops out from the communication network during the time $[t + 1, t']$, algorithm (13a)-(13d) reduces to the following steps for agent $i$ at iterations $k = t + 1, t + 2, ..., t'$:

$$y_{(i)}^k = \theta_k x_{(i)}^k + (1 - \theta_k)x_{(i)}^{k-1}, \quad (14a)$$

$$s_{(i)}^k = \delta_{(i)}^k + \nabla f_{(i)}(y_{(i)}^k) - \nabla f_{(i)}(y_{(i)}^{k-1}), \quad (14b)$$

$$z_{(i)}^{k+1} = \frac{1}{1 + \alpha \theta_k} \left( \frac{\mu \alpha}{\theta_k} y_{(i)}^k + z_{(i)}^k \right) - \frac{\alpha}{\theta_k} s_{(i)}^k, \quad (14c)$$

$$x_{(i)}^{k+1} = \theta_k z_{(i)}^{k+1} + (1 - \theta_k)x_{(i)}^k, \quad (14d)$$

which are a series of local updates without communications. When joining the network again, we require agent $i$ to make up the delayed computations by performing (14a)-(14d) for $t' - t$ iterations. Note that (14a)-(14d) has much lower cost than the same number of iterations (13a)-(13d) because the CPU speed is much faster than the communication speed over TCP/IP or the slow WiFi (Lan et al., 2020).

2.3. Special Cases over Static Graphs

When we fix $W^k = W$, algorithm (13a)-(13d) can be applied to static graphs. As a special case of Theorems 1 and 2, we have the following theorems over static graphs.

Theorem 3  Suppose that Assumptions 1 and 2 hold with connected graphs and $\mu = 0$. Let the sequence $\{\theta_k\}_{k=0}^K$ satisfy $1 - \theta_k = \frac{1}{\sigma_k}$ with $\theta_0 = 1$, $\alpha \leq \frac{(1 - \sigma)\theta_0}{5\sigma L}$. Then for algorithm (13a)-(13d) with fixed gossip matrix $W$, we have for any $K \geq 1$

$$F(\pi^{K+1}) - F(x^*) \leq \frac{1}{\alpha(K + 1)^2} \left( \frac{2}{\alpha} \|x^0 - x^*\|^2 + \frac{\alpha(1 - \sigma)}{2mL} \|\Pi x^0\|^2 \right),$$

and

$$\frac{1}{\alpha} \|\Pi x^K\|^2 \leq \frac{1}{\alpha L(K + 1)^2} \left( 5 \|x^0 - x^*\|^2 + \frac{9\alpha(1 - \sigma)}{4mL} \|\Pi x^0\|^2 \right).$$

Theorem 4  Suppose that Assumptions 1 and 2 hold with connected graphs and $\mu > 0$. Let $\alpha \leq \frac{(1 - \sigma)^2}{116L}$ and $\theta_k = \alpha = \sqrt{\frac{\mu}{2}}$. Then for algorithm (13a)-(13d) with fixed gossip matrix $W$, we have for any $K \geq 1$

$$F(\pi^{K+1}) - F(x^*) + \left( \frac{\theta^2}{2\alpha} + \frac{\mu \theta}{2} \right) \|\pi^{K+1} - x^*\|^2 \leq (1 - \theta)\gamma\pi^{K+1} C,$$
and
\[
\frac{1}{m} \|\Pi x^K\|^2 \leq (1 - \theta)^{K+1} \frac{4C}{L},
\]
where \( C = F(x^0) - F(x^*) + \left( \frac{\theta^2}{2m} + \frac{\mu_0}{2} \right) \|z^0 - x^*\|^2 + \frac{4(1-\sigma)}{9\mu_5 \nu_{mL}(1-\theta)} \|\Pi s^0\|^2. \)

The above theorems give the \( \mathcal{O}\left(\frac{1}{(1-\sigma)^2} \sqrt{\frac{L}{\epsilon}}\right) \) and \( \mathcal{O}\left(\frac{L}{\mu(1-\sigma)} \log \frac{1}{\epsilon}\right) \) convergence rates for nonstrongly convex and strongly convex problems, respectively. As illustrated in Table 1, our convergence rates significantly improve over the ones of \( \mathcal{O}\left(\frac{1}{r_{mL}^2} \sqrt{\frac{L}{\epsilon}}\right) \) and \( \mathcal{O}\left(\frac{L}{\mu(1-\sigma)} \log \frac{1}{\epsilon}\right) \), respectively, which were originally proved in (Qu & Li, 2020).

**Remark 6** In our Theorem 4, we require each \( f_i(x) \) to be strongly convex. Some literatures study the weaker assumptions where only \( F(x) \) is required to be strongly convex and each \( f_i(x) \) can be convex and smooth. Sun et al. (2022) established the \( \mathcal{O}\left(\frac{L}{\mu^1(1-\sigma)} \log \frac{1}{\epsilon}\right) \) complexity for gradient tracking over general undirected graphs. As a comparison, when each \( f_i(x) \) is strongly convex, the state-of-the-art complexity of gradient tracking is \( \mathcal{O}\left(\frac{L}{\mu^1} \log \frac{1}{\epsilon}\right) \) (Alghunaim et al., 2021). Currently, it is unclear how to combine our techniques with those in (Sun et al., 2022) and we conjecture that the complexity would be higher than the one given in Theorem 4. On the other hand, for some algorithms relying on multi-consensus (Ye et al., 2023; 2020), the weaker assumptions have no influence on the complexity.

### 2.4. Improved Dependence on the Network Connectivity Constants

As shown in Tables 1 and 2, the dependence on the network connectivity constants in our complexities is not optimal. We improve it over static graphs and time-varying graphs in the next two sections, respectively.

#### 2.4.1. Chebyshev Acceleration over Static Graphs

Chebyshev acceleration was first used to accelerate distributed algorithms by Scaman et al. (2017), and it has become a standard technique now. Define the Chebyshev polynomials as \( T_0(x) = 1, T_1(x) = x, \) and \( T_{k+1}(x) = 2xT_k(x) - T_{k-1}(x) \) for all \( k \geq 1 \). For symmetric \( W \), define \( \lambda = I - W \) with \( 2 \geq \lambda_1 \geq \lambda_2 \geq ... \geq \lambda_m \geq 0 \) being its eigenvalues. We know \( \lambda_m \geq 1 - \sigma \). Define \( \nu = \frac{\lambda_{m-1}}{\lambda_1}, c_1 = \frac{1 - \sqrt{\nu}}{1 + \sqrt{\nu}}, \) \( c_2 = \frac{1 + \nu}{1 - \nu}, \) \( c_3 = \frac{2}{\lambda_1 + \lambda_{m-1}}, \) and \( P_t(x) = 1 - \frac{T_1(c_2)(1-x)}{T_1(c_2)} \). Then, \( P_t(c_3 A) \) is a symmetric matrix satisfying \( P_t(c_3 A) \mathbf{1} = 0 \) with its spectrum in \( [1 - \frac{2c_1}{1+c_1^2}, 1 + \frac{2c_1}{1+c_1^2}] \cup [0, \frac{1}{2}] \) (Auzinger & Melenk, 2017). Let \( t = \frac{1}{\sqrt{\nu}} \) so that \( c_1 \leq \frac{1}{k} \) and \( [1 - \frac{2c_1^2}{1+c_1^2}, 1 + \frac{2c_1^2}{1+c_1^2}] \subseteq [0.35, 1.65] \). Thus, we can replace the fixed gossip matrix \( W \) in algorithm (13a)-(13d) by \( I - P_t(c_3 A) \) because its second largest singular value \( \sigma' \) satisfies \( \sigma' \leq 0.65 \), which is independent of \( 1 - \sigma \). From Theorems 3 and 4 with \( \sigma \) replaced by \( \sigma' \), we see that the algorithm needs \( \mathcal{O}\left(\sqrt{\frac{L}{\nu}}\right) \) iterations for nonstrongly convex problems and \( \mathcal{O}\left(\frac{L}{\mu(1-\sigma)} \log \frac{1}{\epsilon}\right) \) iterations for strongly convex ones to find an \( \epsilon \)-optimal solution, which corresponds to the gradient oracle complexity. On the other hand, we can compute \( (I - P_t(c_3 A)) x \) by the following procedure (Scaman et al., 2017):

```
Input: x. Initialize: a_0 = 0, a_1 = c_2. z^0 = x, z^1 = c_2 (I - c_3 A) x.
for s = 1, 2, ..., t - 1 do
    a_{s+1} = 2c_2a_s - a_{s-1},
    z^{s+1} = 2c_2(I - c_3 A) z^s - z^{s-1}.
end for
Output: (I - P_t(c_3 A)) x = z^t/a_t.
```

Thus, the communication round complexities for nonstrongly convex and strongly convex problems are \( \mathcal{O}\left(\sqrt{\frac{L}{(1-\sigma)^2}}\right) \) and \( \mathcal{O}\left(\frac{L}{\mu(1-\sigma)} \log \frac{1}{\epsilon}\right) \), respectively.

**Corollary 1** Under the settings of Theorem 3 with symmetric and fixed gossip matrix \( W \), algorithm (13a)-(13d) with Chebyshev acceleration requires time of \( \mathcal{O}\left(\frac{L}{(1-\sigma)^2}\right) \) communication rounds and \( \mathcal{O}\left(\sqrt{\frac{L}{\nu}}\right) \) gradient oracle calls to find an \( \epsilon \)-optimal averaged solution such that \( F(\overline{x}) - F(x^*) \leq \epsilon \).
Corollary 2 Under the settings of Theorem 4 with symmetric and fixed gossip matrix $W$, algorithm (13a)-(13d) with Chebyshev acceleration requires time of $O\left(\sqrt{\frac{L}{\mu}} \log \frac{1}{\epsilon} \right)$ communication rounds and $O\left(\sqrt{\frac{L}{\mu}} \log \frac{1}{\epsilon} \right)$ gradient oracle calls to find an $\epsilon$-optimal averaged solution such that $F(\bar{x}) - F(x^*) \leq \epsilon$.

2.4.2. Multiple Consensus over Time-Varying Graphs

Although Chebyshev acceleration has been widely used in decentralized optimization, it is unclear how to extend it to time-varying graphs. In this section, we use a multiple consensus subroutine as an alternative to improve the dependence on the network connectivity constants. Motivated by Chebyshev acceleration, our idea is to replace $W^k$ in (13a)-(13d) by virtual gossip matrices $W^{k}\zeta$ with carefully designed $\zeta$ such that

$$\|\Pi W^{k}\zeta x\| \leq \frac{1}{e} \|\Pi x\|, \quad r = 1, 2, 3.$$ 

Here, $\frac{1}{e}$ can be replaced by any constant not close to 1. Then, it can be regarded as running the resultant algorithm over time-varying graphs with each graph instance being connected at every time, and moreover, $\sigma = \frac{1}{e}$. Note that we do not require the symmetry of the gossip matrices in Assumptions 2 and 3, thus our theorems apply to the virtual gossip matrices $W^{k}\zeta$. From Theorems 1 and 2 with $\gamma = 1$ and $\sigma \gamma = \frac{1}{e}$, we see that $O\left(\sqrt{\frac{L}{\mu}}\right)$ iterations for nonstrongly convex problems and $O\left(\sqrt{\frac{L}{\mu \log \frac{1}{\epsilon}}}\right)$ for strongly convex problems suffice to find an $\epsilon$-optimal solution, which correspond to the gradient oracle complexity. Next, we consider the communication round complexity. Letting $\zeta = \left[\frac{1}{\sqrt{1-\sigma \gamma}}\right]$, it follows from (9) that

$$\|\Pi W^{k}\zeta x\| \leq \sigma_{\gamma}^{\frac{1}{1-\sigma \gamma}} \|\Pi x\| = (1 - (1 - \sigma \gamma))^{\frac{1}{1-\sigma \gamma}} \|\Pi x\| \leq \frac{1}{e} \|\Pi x\|,$$

where we use the fact that $(1 - x)^{1/\epsilon} \leq 1/e$ for any $x \in (0, 1)$. Since $W^{k}\zeta\zeta x$ can be implemented by the multiple consensus subroutine

$$u^{t+1} = W^t u^t,$$

with $\zeta$ rounds of communications initialized at $u^0 = x$, the communication round complexity is $O\left(\frac{\sqrt{L}}{1-\sigma \gamma} \sqrt{\frac{L}{\mu}} \right)$ for nonstrongly convex problems and $O\left(\frac{\sqrt{L}}{1-\sigma \gamma} \sqrt{\frac{L}{\mu \log \frac{1}{\epsilon}}}\right)$ for strongly convex ones, respectively.

Corollary 3 Under the settings of Theorem 1, algorithm (13a)-(13d) combined with the multiple consensus subroutine requires time of $O\left(\frac{L}{1-\sigma \gamma} \sqrt{\frac{L}{\mu}} \right)$ communication rounds and $O\left(\sqrt{\frac{L}{\mu \log \frac{1}{\epsilon}}}\right)$ gradient oracle calls to find an $\epsilon$-optimal averaged solution such that $F(\bar{x}) - F(x^*) \leq \epsilon$.

Corollary 4 Under the settings of Theorem 2, algorithm (13a)-(13d) combined with the multiple consensus subroutine requires time of $O\left(\frac{L}{1-\sigma \gamma} \sqrt{\frac{L}{\mu \log \frac{1}{\epsilon}}}\right)$ communication rounds and $O\left(\sqrt{\frac{L}{\mu \log \frac{1}{\epsilon}}}\right)$ gradient oracle calls to find an $\epsilon$-optimal averaged solution such that $F(\bar{x}) - F(x^*) \leq \epsilon$.

Remark 7 The multiple consensus subroutine is only for the theoretical purpose. It may be impractical in a realistic time-varying network because communication has been recognized as the major bottleneck in distributed optimization. The multiple consensus may place a larger communication burden in practice, although it gives theoretically lower communication round complexities. A similar issue also happens in APM (Li et al., 2020a) and DAGD-C (Rogozin et al., 2021b), which also need a multiple consensus subroutine.

On the other hand, decentralized optimization over time-varying graphs is important because of two reasons. Firstly, in many applications, the communication network varies with time, and algorithms for this scenario are needed. Secondly, many other scenarios can be reformulated as optimization over time-varying graphs, such as asynchrony (Spiridonoff et al., 2020), local SGD (Koloskova et al., 2020), and sparsification (Chen et al., 2022). In these scenarios, the real network may be fixed, and the time-varying graphs are only used for analysis. So the single loop methods are much more favored.

Remark 8 Unlike the scenario over static graphs, the communication round complexity lower bounds over $\gamma$-connected time-varying graphs have not been established, and it is unclear whether the $O\left(\frac{L}{1-\sigma \gamma} \sqrt{\frac{L}{\mu}}\right)$ and $O\left(\frac{L}{1-\sigma \gamma} \sqrt{\frac{L}{\mu \log \frac{1}{\epsilon}}}\right)$
communication round complexities can be further improved. We leave it as an open problem. On the other hand, Kovalev et al. (2021a) established the $O\left(\frac{1}{\sqrt{\mu}} \sqrt{\frac{L}{\mu} \log \frac{1}{\epsilon}}\right)$ communication round complexity lower bound and the $O\left(\sqrt{\frac{L}{\mu} \log \frac{1}{\epsilon}}\right)$ gradient oracle complexity lower bound for the special scenario of connected graphs at every time. That is, $\gamma = 1$ in our scenario.

3. Proofs of Theorems

In this section, we prove the theorems in Sections 2.2 and 2.3. We first reformulate algorithm (13a)-(13d) as the inexact accelerated gradient descent (Devolder et al., 2014) in the sense that we use the column stochasticity of $1^\top W^k = 1^\top$. From the initialization $s^0 = \nabla f(y^0)$ and (15b), we have the following standard but important property in gradient tracking:

$$s^k = \frac{1}{m} \sum_{i=1}^{m} \nabla f_i(y_i^k).$$

Iterations (15a)-(15d) can be regarded as the inexact accelerated gradient descent (Devolder et al., 2014) in the sense that we use $\frac{1}{m} \sum_{i=1}^{m} \nabla f_i(y_i^k)$ as the descent direction, rather than the true gradient $\frac{1}{m} \sum_{i=1}^{m} \nabla f_i(y^k)$. In fact, when we replace $s^k$ in step (15c) by the true gradient, steps (15a), (15c), and (15d) reduce to the updates of the standard accelerated gradient descent, see (Nesterov, 2004; Lin et al., 2020) for example.

The next lemma demonstrates the analogy properties of convexity and smoothness with the inexact gradients. The proof can be found in (Jakovetić et al., 2014a; Qu & Li, 2020). For the completeness and the readers’ convenience, we give the proof in the appendix.

**Lemma 1** Define

$$f(\bar{y}^k, y^k) = \frac{1}{m} \sum_{i=1}^{m} \left( f_i(y_i^k) + \left< \nabla f_i(y_i^k), \bar{y}^k - y_i^k \right> \right).$$

Suppose that Assumption 1 holds. Then, we have for any $w$,

$$F(w) \geq f(\bar{y}^k, y^k) + \left< s^k, w - \bar{y}^k \right> + \frac{\mu}{2} \| w - \bar{y}^k \|^2,$$

$$F(w) \leq f(\bar{y}^k, y^k) + \left< s^k, w - \bar{y}^k \right> + \frac{L}{2} \| w - \bar{y}^k \|^2 + \frac{L}{2m} \| \Pi y^k \|^2.$$

Especially, we allow $\mu$ to be zero.
Define the Bregman divergence as follows:

\[
D_f(x, y^k) = \frac{1}{m} \sum_{i=1}^{m} \left( f_i(x) - f_i(y_i^k) - \left\langle \nabla f_i(y_i^k), x - y_i^k \right\rangle \right).
\]  

The next lemma gives the convergence rates of the inexact accelerated gradient descent. The techniques in this proof are standard, see (Lin et al., 2020) for example. The crucial difference is that we keep the Bregman divergence term \(D_f(x, y^k)\) in (21) and (22), which is motivated by (Tseng, 2008).

Compared with the standard accelerated gradient descent, for example, see (Nesterov, 2004; Lin et al., 2020), there are two additional error terms \((a)\) and \((c)\) in our lemma due to the inexact gradients. In the next two sections, we bound the two terms carefully by \((b)\) and \((d)\), respectively, such that the convergence rates of the accelerated gradient tracking match those of the classical centralized accelerated gradient descent, which is the main technical contribution of this paper compared with the existing work on accelerated gradient tracking in (Qu & Li, 2020).

**Lemma 2** Suppose that Assumption 1 with \(\mu = 0\) and part 2 of Assumption 3 hold. Let the sequence \(\{\theta_k\}_{k=0}^{K}\) satisfy \(1 - \frac{\theta_k}{\theta_k^2} = \frac{1}{\theta_k}\) with \(\theta_0 = 1\). Then for algorithm (13a)-(13d), we have

\[
\begin{align*}
& \frac{F(\pi^{k+1}) - F(x^*)}{\theta_k^2} + \frac{1}{2\alpha} \|\pi^{k+1} - x^*\|^2 \leq \frac{1}{2\alpha} \|\pi^0 - x^*\|^2 \\
& \quad + \sum_{k=0}^{K} \frac{L}{2m\theta_k} \|\Pi y^k\|^2 - \sum_{k=0}^{K} \left( \frac{1}{2\alpha} - \frac{L}{2} \right) \|\pi^{k+1} - x^*\|^2 + \frac{1}{\theta_k} D_f(x^k, y^k) .
\end{align*}
\]

Suppose that Assumption 1 with \(\mu > 0\) and part 2 of Assumption 3 hold. Let \(\theta_k = \sqrt{1 - \theta} \frac{\sqrt{m}}{2}\) for all \(k\) and assume that \(\alpha \mu \leq 1\). Then for algorithm (13a)-(13d), we have

\[
\begin{align*}
& \frac{1}{(1 - \theta)^{k+1}} \left( F(\pi^{k+1}) - F(x^*) + \left( \frac{\theta^2}{2\alpha} + \frac{\mu \theta}{2} \right) \|\pi^{k+1} - x^*\|^2 \right) \\
& \quad \leq F(\pi^k) - F(x^*) + \left( \frac{\theta^2}{2\alpha} + \frac{\mu \theta}{2} \right) \|\pi^0 - x^*\|^2 + \sum_{k=0}^{K} \frac{L}{2m(1 - \theta)^{k+1}} \|\Pi y^k\|^2 \\
& \quad - \sum_{k=0}^{K} \left( \frac{1}{(1 - \theta)^{k+1}} \left( \frac{\theta^2}{2\alpha} - \frac{L \theta^2}{2} \right) \|\pi^{k+1} - x^*\|^2 + \frac{1}{(1 - \theta)^k} D_f(x^k, y^k) \right) .
\end{align*}
\]

**Proof 1** From the inexact smoothness (19), we have

\[
F(\pi^{k+1}) \leq f(\theta_k, y^k) + \frac{L}{2} \|\pi^{k+1} - y^k\|^2 + \frac{L}{2m} \|\Pi y^k\|^2 \\
= f(\theta_k, y^k) + \theta_k \left( \frac{L \theta_k^2}{2} \|\pi^{k+1} - x^*\|^2 + \frac{L}{2m} \|\Pi y^k\|^2 \right) \\
= f(\theta_k, y^k) + \theta_k \left( \frac{L \theta_k^2}{2} \|\pi^{k+1} - x^*\|^2 + \frac{L}{2m} \|\Pi y^k\|^2 \right) + \frac{L}{2m} \|\Pi y^k\|^2, 
\]
where we use (15a) and (15d) in \(\Delta\). Next, we bound the two inner product terms. For the first inner product, we have

\[
f(y^k, y^k) + \theta_k \langle \bar{x}^k, x^* - x^k \rangle \\
= \frac{b}{m} f(y^k, y^k) + \langle \bar{x}^k, \theta_k x^* + (1 - \theta_k) \bar{x}^k - y^k \rangle \\
= \theta_k \left( f(y^k, y^k) + \langle \bar{x}^k, x^* - y^k \rangle \right) + (1 - \theta_k) \left( f(y^k, y^k) + \langle \bar{x}^k, \bar{x}^k - y^k \rangle \right) \\
\leq \theta_k F(x^*) - \frac{\mu \theta_k}{2} \| y^k - x^* \|^2 + \frac{1 - \theta_k}{m} \sum_{i=1}^{m} \left( f(i)(y_{i(i)}) + \left( \nabla f(i)(y_{i(i)}) \right, \bar{x}^k - y_{i(i)} \right) \right) \\
= \theta_k F(x^*) - \frac{\mu \theta_k}{2} \| y^k - x^* \|^2 + (1 - \theta_k) F(x^k) \\
- \frac{1 - \theta_k}{m} \sum_{i=1}^{m} \left( f(i)(x^k) - f(i)(y_{i(i)}) - \left( \nabla f(i)(y_{i(i)}) \right, \bar{x}^k - y_{i(i)} \right) \right) \\
= \theta_k F(x^*) - \frac{\mu \theta_k}{2} \| y^k - x^* \|^2 + (1 - \theta_k) F(x^k) - (1 - \theta_k) D_f(x^k, y^k),
\]

where we use (15a) in \(\triangleleft\), (18), (17), and (16) in \(\triangleright\). For the second inner product, we have

\[
\theta_k \langle \bar{x}^k, \bar{x}^{k+1} - x^* \rangle \overset{d}{=} - \frac{\theta_k^2}{\alpha} \left( \bar{x}^{k+1} - \bar{x}^k + \frac{\mu \theta_k}{\theta_k} \left( \bar{x}^{k+1} - y^k \right) \right, \bar{x}^{k+1} - x^* \right) \\
= \frac{\theta_k^2}{2\alpha} \left( \| \bar{x}^{k+1} - x^* \|^2 - \| \bar{x}^{k+1} - x^* \|^2 - \| \bar{x}^{k+1} - \bar{x}^k \|^2 \right) \\
+ \frac{\mu \theta_k}{2} \left( \| \bar{x}^{k+1} - x^* \|^2 - \| \bar{x}^{k+1} - x^* \|^2 - \| \bar{x}^{k+1} - \bar{x}^k \|^2 \right),
\]

where we use (15c) in \(\triangleleft\). Plugging into (23) and rearranging the terms, it gives

\[
F(\bar{x}^{k+1}) - F(x^*) + \left( \frac{\theta_k^2}{2\alpha} + \frac{\mu \theta_k}{2} \right) \| \bar{x}^{k+1} - x^* \|^2 \\
\leq (1 - \theta_k)(F(\bar{x}^k) - F(x^*)) + \frac{\theta_k^2}{2\alpha} \| \bar{x}^{k} - x^* \|^2 \\
- \left( \frac{\theta_k^2}{2\alpha} - \frac{L \theta_k^2}{2} \right) \| \bar{x}^{k+1} - \bar{x}^{k} \|^2 - (1 - \theta_k) D_f(x^k, y^k) + \frac{L}{2m} \| \Pi y^k \|^2.
\]

**Case 1:** Each \(f(i)\) is nonstrongly convex. In this case, (24) holds with \(\mu = 0\). Dividing both sides of (24) by \(\theta_k^2\), summing over \(k = 0, 1, ..., K\), using \(\frac{1 - \theta_k}{\theta_k^2} = \frac{1}{\theta_k^2-1}\) and \(\theta_0 = 1\), we have (21).

**Case 2:** Each \(f(i)\) is \(\mu\)-strongly convex. Letting \(\theta_k = \frac{\alpha \mu}{2} - \frac{s}{\alpha \mu}\) for all \(k\), we know \(\theta_k^2 \leq \left( \frac{\alpha \mu}{2} + \frac{\alpha \mu}{2} - \frac{s}{\alpha \mu} \right) (1 - \theta)\) holds if \(\alpha \mu \leq 1\). Dividing both sides of (24) by (1 - \(\theta\))\(k+1\) and summing over \(k = 0, 1, ..., K\), it gives (22).

### 3.2. Bounding the Consensus Errors over Static Graphs

In this section, we bound the term (a) by (b) appeared in (21), and the term (c) by (d) in (22) over static graphs. We first bound \(\| \Pi y^{k+1} \|^2\) in the next lemma. The crucial trick is to construct a linear combination of the consensus errors with carefully designed weights such that it shrinks geometrically with an additional error term. Moreover, the step size \(\alpha\) remains to be a constant of the order \(O(\frac{1}{\tau})\) as large as possible. Another trick is that we use a constant \(\tau\) to balance \(D_f(\bar{x}^{k+1}, \bar{x}^{r+1})\) and \(\| \bar{x}^{r+1} - \bar{x}^{r} \|^2\) in \(\Psi\), which is generated by Young’s inequality and will be specified later.

**Lemma 3** Suppose that Assumptions 1 and 2 hold with \(\mu \geq 0\). Let \(\alpha \leq \frac{(1 - \sigma^3)}{80L \sqrt{1 + \epsilon}}\) and the sequence \(\{\theta_k\}_{k=0}^{K}\) satisfy \(\theta_{k+1} \leq \theta_k \leq 1\). Then for algorithm (13a)-(13d) with fixed gossip matrix \(W\), we have

\[
\max \left\{ \| \Pi y^{k+1} \|^2, \| \Pi x^{k+1} \|^2 \right\} \leq C_1 \rho^{k+1} + C_2 \sum_{r=0}^{k} \rho^{k-r} \theta_r^2 \rho^r,
\]

(25)
where $\rho = 1 - \frac{1 - \sigma}{4}$, $C_1 = \frac{(1 - \sigma)^2}{18(1 + \frac{\tau}{\theta})L^4}$, $C_2 = \frac{1 - \sigma}{9(1 + \frac{\tau}{\theta})L^4}$,

$$\Phi^r = \frac{2mL(1 + \tau)}{\theta^2} D_f(\bar{x}^{r+1}, y^{r+1}) + 2mL^2 \left(1 + \frac{1}{\tau}\right) \| \bar{z}^{r+1} - \bar{z}^r \|^2,$$

(26)

and $\tau$ can be any positive constant.

Proof 2 Multiplying both sides of (13a)-(13d) by $\Pi$, using (6) and $\| \Pi x \| \leq \| x \|$, we have

$$\| \Pi y^k \| \leq \theta_k \| \Pi x^k \| + (1 - \theta_k) \| \Pi x_k \| \leq \theta_k \| \Pi z^k \| + \| \Pi x^k \|,$$

(27)

$$\| \Pi s^{k+1} \| \leq \sigma \| \Pi s^k \| + \| \nabla f(x^{k+1}) - \nabla f(y^k) \|,$$

(28)

$$\| \Pi z^{k+1} \| \leq \sigma \left( \frac{\mu \alpha}{\theta_k + \mu \alpha} \| \Pi y^k \| + \frac{\theta_k}{\theta_k + \mu \alpha} \| \Pi z^k \| \right) + \frac{\alpha}{\theta_k + \mu \alpha} \| \Pi s^k \|$$

(29)

$$\leq \sigma \| \Pi z^k \| + \frac{\mu \alpha}{\theta_k + \mu \alpha} \| \Pi x^k \| + \frac{\alpha}{\theta_k + \mu \alpha} \| \Pi s^k \|,$$

(30)

where $a \leq$ uses (27), $b \leq$ uses $\sigma < 1$ and $\frac{(\mu \alpha + 1) \theta_k}{\theta_k + \mu \alpha} \leq 1$ with $\theta_k \leq 1$. Next, we bound $\| \nabla f(y^{k+1}) - \nabla f(y^k) \|$.  

$$\| \nabla f(y^{k+1}) - \nabla f(y^k) \|^2 \leq \frac{m}{\theta_k} \left( \| \nabla f_i(y_i^{k+1}) - \nabla f_i(y_i^k) \|^2 \right)$$

$$\leq \sum_{i=1}^{m} \left(1 + \frac{1}{\tau}\right)^2 \left( \| \nabla f_i(x_i) - \nabla f_i(y_i) \|^2 \right)$$

(31)

where $c \leq$ uses Young’s inequality of $\| a - b \|^2 \leq (1 + \tau) \| a \|^2 + (1 + \frac{1}{\tau}) \| b \|^2$ for any $\tau > 0$, $d \leq$ uses (5), the smoothness of $f_i$, and the definition of $D_f$ in (20), $e \leq$ uses (15a), (15d), and the definition of $\Pi y$ in (4), $f \leq$ uses (27). Denote $c_0 = 4L^2 \left(1 + \frac{1}{\tau}\right)$ for simplicity in the remaining proof of this lemma.

Squaring both sides of (28), it follows that

$$\| \Pi s^{k+1} \|^2 \leq \left(1 + \frac{1 - \sigma}{2\sigma}\right) \sigma^2 \| \Pi s^k \|^2 + \left(1 + \frac{2\sigma}{1 - \sigma}\right) \| \nabla f(y^{k+1}) - \nabla f(y^k) \|^2$$

(32)
where we use \( \sigma < 1 \) and (31) in \( \lessdot \). Similarly, for (29) and (30), we also have

\[
\|\Pi z^{k+1}\|^2 \leq \frac{1 + \sigma}{2} \|\Pi z^k\|^2 + \frac{4}{1 - \sigma} \left( \frac{\mu^2 \alpha^2}{\theta_k^2} \|\Pi x^k\|^2 + \alpha^2 \|\Pi s^k\|^2 \right), \tag{33}
\]

\[
\|\Pi x^{k+1}\|^2 \leq \frac{1 + \sigma}{2} \|\Pi x^k\|^2 + \frac{2\theta_k^2}{1 - \sigma} \|\Pi z^{k+1}\|^2. \tag{34}
\]

Adding (32), (33), and (34) together with the weights \( c_1, c_2 \theta_{k+1}^2, \) and \( c_3 \), respectively, we have

\[
c_1 \|\Pi s^{k+1}\|^2 + c_2 \theta_{k+1}^2 \|\Pi z^{k+1}\|^2 + c_3 \|\Pi x^{k+1}\|^2
\]

\[
\leq c_1 \|\Pi s^k\|^2 + \left( c_2 \theta_k^2 + \frac{2c_3 \theta_k^2}{1 - \sigma} \right) \|\Pi z^{k+1}\|^2 + \frac{c_3 (1 + \sigma)}{2} \|\Pi x^k\|^2
\]

\[
\leq \left( \frac{c_1 (1 + \sigma)}{2} + \left( c_2 + \frac{2c_3}{1 - \sigma} \right) \frac{4\alpha^2}{1 - \sigma} \right) \|\Pi s^k\|^2
\]

\[
+ \left( \frac{2c_0 c_1}{1 - \sigma} + \left( c_2 + \frac{2c_3}{1 - \sigma} \right) \frac{1 + \sigma}{2} \right) \theta_k^2 \|\Pi z^k\|^2
\]

\[
+ \left( \frac{2c_0 c_1}{1 - \sigma} + \left( c_2 + \frac{2c_3}{1 - \sigma} \right) \frac{4\mu^2 \alpha^2}{1 - \sigma} + \frac{c_3 (1 + \sigma)}{2} \right) \|\Pi x^k\|^2 + \frac{2c_1}{1 - \sigma} \theta_k^2 \Phi_k,
\]

where we use \( \theta_{k+1} \leq \theta_k \) and (34) in \( \lessdot \). Letting \( c_3 = \frac{9c_0 c_1}{(1 - \sigma)^4}, \quad c_2 = \frac{80c_0 c_1}{(1 - \sigma)\mu^5}, \quad c_1 \geq \frac{8c_0 c_1}{(1 - \sigma)\mu^5}, \) and \( \alpha^2 \leq \min \left\{ \frac{1 - \sigma^2}{1600c_0^2}, \frac{1 - \sigma^2}{1600\mu^2} \right\} \) such that

\[
\frac{c_1 (1 + \sigma)}{2} + \left( c_2 + \frac{2c_3}{1 - \sigma} \right) \frac{4\alpha^2}{1 - \sigma} \leq \frac{c_1 (1 + \sigma)}{2} + \frac{400c_0 c_1 \alpha^2}{(1 - \sigma)^5} \leq \frac{c_1 (3 + \sigma)}{4},
\]

\[
\frac{2c_0 c_1}{1 - \sigma} + \left( c_2 + \frac{2c_3}{1 - \sigma} \right) \frac{1 + \sigma}{2} \leq \frac{2c_0 c_1}{1 - \sigma} + \frac{c_2 (1 + \sigma)}{2} \leq \frac{c_2 (3 + \sigma)}{4},
\]

\[
\frac{2c_0 c_1}{1 - \sigma} + \left( c_2 + \frac{2c_3}{1 - \sigma} \right) \frac{4\mu^2 \alpha^2}{1 - \sigma} + \frac{c_3 (1 + \sigma)}{2} \leq \frac{2c_0 c_1}{1 - \sigma} + \frac{400c_0 c_1 \mu^2 \alpha^2}{(1 - \sigma)^5} + \frac{c_3 (1 + \sigma)}{2} \leq \frac{c_3 (3 + \sigma)}{4},
\]

we have

\[
c_1 \|\Pi s^{k+1}\|^2 + c_2 \theta_{k+1}^2 \|\Pi z^{k+1}\|^2 + c_3 \|\Pi x^{k+1}\|^2
\]

\[
\leq \frac{3 + \sigma}{4} \left( c_1 \|\Pi s^k\|^2 + c_2 \theta_k^2 \|\Pi z^k\|^2 + c_3 \|\Pi x^k\|^2 \right) + \frac{2c_1}{1 - \sigma} \theta_k^2 \Phi_k
\]

\[
\leq \left( \frac{3 + \sigma}{4} \right)^{k+1} \left( c_1 \|\Pi s^0\|^2 + c_2 \theta_0^2 \|\Pi z^0\|^2 + c_3 \|\Pi x^0\|^2 \right) + \frac{2c_1}{1 - \sigma} \sum_{r=0}^{k} \left( \frac{3 + \sigma}{4} \right)^{k-r} \theta_r^2 \Phi_r.
\]

From (27), \( c_2 > c_3 \), and the initialization such that \( \Pi x^0 = \Pi y^0 = \Pi z^0 = 0 \), we have

\[
\|\Pi y^{k+1}\|^2 \leq \frac{2}{c_3} \left( c_1 \|\Pi s^{k+1}\|^2 + c_2 \theta_{k+1}^2 \|\Pi z^{k+1}\|^2 + c_3 \|\Pi x^{k+1}\|^2 \right)
\]

\[
\leq \left( \frac{3 + \sigma}{4} \right)^{k+1} \frac{2c_1}{c_3} \|\Pi s^0\|^2 + \frac{4c_1}{c_3 (1 - \sigma)} \sum_{r=0}^{k} \left( \frac{3 + \sigma}{4} \right)^{k-r} \theta_r^2 \Phi_r
\]

\[
= \left( \frac{3 + \sigma}{4} \right)^{k+1} \frac{(1 - \sigma)^2}{18(1 + \frac{\mu}{2})L^2} \|\Pi s^0\|^2 + \frac{1 - \sigma}{9(1 + \frac{\mu}{2})L^2} \sum_{r=0}^{k} \left( \frac{3 + \sigma}{4} \right)^{k-r} \theta_r^2 \Phi_r,
\]

which is exactly (25).

Having (25) at hand, we are ready to bound the term (a) by (b) appeared in (21). The remaining challenge is to upper bound the weighted cumulative consensus errors.
Lemma 4 Suppose that Assumptions 1 and 2 hold with $\mu = 0$. Let the sequence $\{\theta_k\}_{k=0}^K$ satisfy $\frac{1 - \theta_k}{\theta_k} = \frac{1}{\theta_{k-1}}$ with $\theta_0 = 1$, let $\alpha \leq \frac{(1-\sigma)^2}{80L\sqrt{1+\frac{1}{T}}}$, and also suppose Assumptions 1 and 2 hold with Lemma 4. Then for algorithm (13a)-(13d) with fixed gossip matrix $W$, we have

$$\max \left\{ \frac{K}{2m} \sum_{k=0}^{K} \frac{L}{2m\theta^2_k} \|\Pi y^k\|^2, \frac{L}{2m\theta^2_k} \|\Pi x^k\|^2 \right\}$$

$$\leq \frac{16}{3mL(1 + \frac{1}{T})(1 - \sigma)} \|\Pi s^0\|^2 + \frac{11}{mL(1 + \frac{1}{T})(1 - \sigma)^2} \sum_{r=0}^{K-1} \Phi^r,$$

where $\tau$ and $\Phi^r$ are defined in Lemma 3.

Proof 3 We first give some properties of the sequence $\{\theta_k\}_{k=0}^K$. From $\frac{1 - \theta_k}{\theta_k} = \frac{1}{\theta_{k-1}}$ and $\theta_0 = 1$, we have $\theta_k \leq \theta_{k-1}$. Denote $S = \sum_{k=r+1}^{K} \frac{\rho^k}{\theta^2_k}$ for simplicity. We have

$$\rho S = \sum_{k=r+1}^{K} \frac{\rho^{k+1}}{\theta^2_{k-1}} = \sum_{k=r+1}^{K} \frac{\rho^k}{\theta^2_{k-1}} - \frac{\rho^{r+1}}{\theta^2_{r}} + \frac{\rho^{K+1}}{\theta^2_{K}},$$

and

$$S - \rho S = \sum_{k=r+1}^{K} \rho^{k+1} \left( \frac{1}{\theta^2_k} - \frac{1}{\theta^2_{k-1}} \right) + \rho^{r+1} \frac{\theta^2_{r}}{\theta^2_{r}} - \rho^{K+1} \frac{\theta^2_{K}}{\theta^2_{K}} \leq \sum_{k=r+1}^{K} \rho^k \frac{\theta^2_{k-1}}{\theta^2_{r}} + \rho^{r+1} + \rho^{K+1} \frac{\theta^2_{K}}{\theta^2_{r}} - \rho^{K+1} \frac{\theta^2_{K}}{\theta^2_{K}},$$

where we use $\frac{1 - \theta_k}{\theta_k} = \frac{1}{\theta_{k-1}}$ in the last inequality. It further gives

$$\rho(1 - \rho) S = \sum_{k=r+1}^{K} \rho^k \frac{\theta^2_{k-1}}{\theta^2_{r}} + \rho^{r+2} - \rho^{K+2} \frac{\theta^2_{r}}{\theta^2_{K}} \leq \sum_{k=r+1}^{K} \frac{\rho^k}{\theta^2_{k-1}} - \rho^{r+1} + \rho^{K+1} \frac{\theta^2_{K}}{\theta^2_{r}} - \rho^{K+2} \frac{\theta^2_{r}}{\theta^2_{K}},$$

and

$$(1 - \rho)^2 S = (1 - \rho) S - (1 - \rho) S$$

$$= \sum_{k=r+1}^{K} \rho^k \left( \frac{1}{\theta^2_k} - \frac{1}{\theta^2_{k-1}} \right) + \rho^{r+1} \frac{\theta^2_{r}}{\theta^2_{r}} - \rho^{K+1} \frac{\theta^2_{K}}{\theta^2_{r}} - \rho^{r+1} + \rho^{K+1} \frac{\theta^2_{K}}{\theta^2_{r}} - \rho^{r+2} \frac{\theta^2_{K}}{\theta^2_{r}} + \rho^{K+2} \frac{\theta^2_{K}}{\theta^2_{r}},$$

$$= \sum_{k=r+1}^{K} \rho^k \left( \frac{1}{\theta^2_k} - \frac{1}{\theta^2_{k-1}} \right) + \frac{(1 - \rho) \theta^2_{r}}{\theta^2_{r}} - \frac{(1 - \rho) \theta^2_{K}}{\theta^2_{r}} - \rho^{r+1} + \rho^{K+1} \frac{\theta^2_{K}}{\theta^2_{r}} - \rho^{K+1},$$

$$\leq \sum_{k=r+1}^{K} \rho^k \left( \frac{(1 - \rho) \theta^{r+1}}{\theta^2_{r}} + \rho^{r+1} \frac{\theta^2_{r}}{\theta^2_{K}} \leq \rho^{r+1} \frac{\theta^2_{r}}{1 - \rho} + \frac{2 \rho^{r+1}}{\theta^2_{r}},$$
where we use (36) in \( \leq \). Thus, we get
\[
\sum_{k=0}^{K} \frac{\rho^k}{L^2 k^2} \leq \frac{1}{(1-\rho)^2} \left( \frac{\rho^{k+1}}{1-\rho} + \frac{2\rho^{k+1}}{\theta^2} \right) \leq \frac{3\rho^{k+1}}{(1-\rho)^3 \theta^2}.
\] (38)

Plugging into (37), it follows from \( \Pi y^0 = 0 \) and \( \theta_0 = 1 \) that
\[
\sum_{k=0}^{K} \frac{L}{2m\theta_k^2} \|\Pi y^k\|^2 \leq \sum_{k=0}^{K} \frac{C_1 L \rho}{2m(1-\rho)} + \sum_{k=0}^{K} \frac{C_2 L}{2m(1-\rho)^{1.5}} \sum_{r=0}^{K-1} \Phi^r
\]
\[
\leq \frac{16}{3mL(1+\frac{1}{2})(1-\theta)} \|\Pi \sigma^0\|^2 + \frac{11}{mL(1+\frac{1}{2})(1-\theta)^2} \sum_{r=0}^{K-1} \Phi^r,
\]
where the last inequality uses the definitions of \( C_1, C_2, \) and \( \rho \) given in Lemma 3. Replacing \( \|\Pi y^k\| \) by \( \|\Pi x^k\| \) in the above analysis, we have the same bound for \( \sum_{k=0}^{K} \frac{L}{2m\theta_k^2} \|\Pi x^k\|^2 \).

In the next lemma, we bound the term (c) by (d) appeared in (22) in a similar way to the proof of Lemma 4.

**Lemma 5** Suppose that Assumptions 1 and 2 hold with \( \mu > 0 \). Let \( \alpha \leq \frac{(1-\sigma)^3}{80L^2(1+\frac{1}{2})} \) and \( \theta_k \equiv \theta = \frac{\sqrt{\mu}}{2} \). Then for algorithm (13a)-(13d) with fixed gossip matrix \( W \), we have
\[
\max \left\{ \sum_{k=0}^{K} \frac{L}{2m(1-\theta)^{k+1}} \|\Pi y^k\|^2, \sum_{k=0}^{K} \frac{L}{2m(1-\theta)^{k+1}} \|\Pi x^k\|^2 \right\}
\]
\[
\leq \frac{4(1-\sigma)}{27mL(1+\frac{1}{2})(1-\theta)} \|\Pi \sigma^0\|^2 + \frac{8\theta^2}{27mL(1+\frac{1}{2})} \sum_{r=0}^{K-1} (1-\theta)^{r+1} \Phi^r,
\]
where \( \tau \) and \( \Phi^r \) are defined in Lemma 3.

**Proof 4** From (25), we get
\[
\sum_{k=0}^{K} \frac{L}{2m(1-\theta)^{k+1}} \|\Pi y^k\|^2
\]
\[
\leq \sum_{k=0}^{K} \frac{C_1 L \rho^k}{2m(1-\theta)^{k+1}} + \sum_{k=0}^{K} \frac{C_2 L}{2m(1-\theta)^{k+1}} \sum_{r=0}^{K-1} \rho^{k-1-r} \theta^2 \Phi^r
\]
\[
= \frac{C_1 L}{2m(1-\theta)} \sum_{k=0}^{K} \left( \frac{\rho}{1-\theta} \right)^k + \frac{\theta^2 C_2 L}{2m\rho(1-\theta)} \sum_{k=0}^{K} \left( \frac{\rho}{1-\theta} \right)^k \sum_{r=0}^{K-1} \Phi^r
\]
\[
= \frac{C_1 L}{2m(1-\theta)} \sum_{k=0}^{K} \left( \frac{\rho}{1-\theta} \right)^k + \frac{\theta^2 C_2 L}{2m\rho(1-\theta)} \sum_{r=0}^{K} \Phi^r \sum_{k=r+1}^{K} \left( \frac{\rho}{1-\theta} \right)^k.
\]

From the settings of \( \theta \) and \( \alpha \), we know \( \theta \leq \frac{1-\sigma}{16} \). Thus we have \( \frac{\rho}{1-\theta} < 1, 1-\theta - \rho \geq \frac{3(1-\sigma)}{16} \), and \( \sum_{k=r+1}^{K} \left( \frac{\rho}{1-\theta} \right)^k \leq \left( \frac{\rho}{1-\theta} \right)^r \frac{\rho}{1-\theta - \rho} \) with \( \rho = 1 - \frac{1-\sigma}{4} \). It follows from \( \Pi y^0 = 0 \) that
\[
\sum_{k=0}^{K} \frac{L}{2m(1-\theta)^{k+1}} \|\Pi y^k\|^2 \leq \frac{C_1 L}{2m(1-\theta)} \frac{\rho}{1-\theta - \rho} + \frac{\theta^2 C_2 L}{2m(1-\theta)} \sum_{r=0}^{K-1} (1-\theta)^{r+1}
\]
\[
\leq \frac{4(1-\sigma)}{27mL(1+\frac{1}{2})(1-\theta)} \|\Pi \sigma^0\|^2 + \frac{8\theta^2}{27mL(1+\frac{1}{2})} \sum_{r=0}^{K-1} (1-\theta)^{r+1},
\]
where the last inequality uses the definitions of \( C_1 \) and \( C_2 \) given in Lemma 3 and \( 1-\theta - \rho \geq \frac{3(1-\sigma)}{16} \). Replacing \( \|\Pi y^k\| \) by \( \|\Pi x^k\| \) in the above analysis, we have the same bound for \( \Pi x^k \).
Now, we are ready to prove Theorems 3 and 4. We first prove Theorem 3. The crucial trick in this proof is to make the constant before $D_f(z^k, y^k)$ positive by setting the constant $\tau$ small, and make the constant before $\|z^{t+1} - z^t\|^2$ positive by setting the step size $\alpha$ small. This is the reason why we introduce the constant $\tau$ in the definition of $\Psi^r$ in (26).

**Proof 5** Plugging (35) into (21) and using the definition of $\Phi^r$ in (26), we obtain

\[
\frac{F(z^{K+1}) - F(x^*)}{\theta_K^2} + \frac{1}{2\alpha} \|z^{K+1} - x^*\|^2 \\
\leq \frac{1}{2\alpha} \|z^0 - x^*\|^2 + \frac{16}{3mL(1 + \frac{1}{\tau})(1 - \sigma)} \|\Pi s^0\|^2 \\
- \sum_{k=0}^{K} \left( \frac{1}{2\alpha} - \frac{L}{2} - \frac{22L}{(1 - \sigma)^2} \right) \|z^{t+1} - z^t\|^2 + \frac{1}{\theta_{k-1}} \left( 1 - \frac{22(1 + \tau)}{(1 + \frac{1}{\tau})(1 - \sigma)^2} \right) D_f(z^k, y^k) \\
\leq \frac{1}{2\alpha} \|z^0 - x^*\|^2 + \frac{16}{3mL(1 + \frac{1}{\tau})(1 - \sigma)} \|\Pi s^0\|^2 - \sum_{k=0}^{K} \left( \frac{1}{4\alpha} \|z^{t+1} - z^t\|^2 + \frac{1}{2\theta_{k-1}} D_f(z^k, y^k) \right) \\
\leq \frac{1}{2\alpha} \|z^0 - x^*\|^2 + \frac{1 - \sigma}{8mL} \|\Pi s^0\|^2 - \frac{1}{5mL} \sum_{r=0}^{K-1} \Phi^r,
\]

where in $\leq$ we let $\tau = \frac{(1 - \sigma)^4}{44}$ so to have $\frac{22(1 + \tau)}{(1 + \frac{1}{\tau})(1 - \sigma)^2} = \frac{(1 - \sigma)^4}{44} \leq \frac{(1 - \sigma)^3}{32L\sqrt{1 + \frac{1}{\tau}}}$, and $\frac{1}{4\alpha} \geq \frac{L}{2} + \frac{22L}{(1 - \sigma)^2}$. So we have

\[
F(z^{K+1}) - F(x^*) \leq \theta_K^2 \left( \frac{1}{2\alpha} \|z^0 - x^*\|^2 + \frac{1 - \sigma}{8mL} \|\Pi s^0\|^2 \right),
\]

\[
\frac{1}{5mL} \sum_{r=0}^{K-1} \Phi^r \leq \frac{1}{2\alpha} \|z^0 - x^*\|^2 + \frac{1 - \sigma}{8mL} \|\Pi s^0\|^2.
\]

It follows from (35) that

\[
\max \left\{ \sum_{k=0}^{K} \frac{L}{2m\theta_k^2} \|\Pi y^k\|^2, \sum_{k=0}^{K} \frac{L}{2m\theta_k^2} \|\Pi x^k\|^2 \right\} \\
\leq \frac{16}{3mL(1 + \frac{1}{\tau})(1 - \sigma)} \|\Pi s^0\|^2 + \frac{11}{mL(1 + \frac{1}{\tau})(1 - \sigma)^2} \sum_{r=0}^{K-1} \Phi^r \\
\leq \frac{1 - \sigma}{8mL} \|\Pi s^0\|^2 + \frac{1}{4mL} \sum_{r=0}^{K-1} \Phi^r \\
\leq \frac{5}{8\alpha} \|z^0 - x^*\|^2 + \frac{9(1 - \sigma)}{32mL} \|\Pi s^0\|^2.
\]

From (36), we have the conclusions.

Next, we prove Theorem 4.
As shown in Lemma 3, to bound the consensus errors, we construct a linear combination of the consensus errors such that it shrinks geometrically with an additional error term. As a comparison, Qu & Li (2020) used the linear system inequality, corresponding term in their (53), which gives the slower convergence rate of \( O\left(\frac{1}{k^\gamma}\right) \). For nonstrongly convex problems, Qu & Li (2020) set the step size of the order \( \frac{r}{mL} \), which is generated by the consensus errors and is an analogy to our term \( D_k(x^k, y^k) \) generated in (31), by setting much smaller step sizes than ours. See (32) and (53) in (Qu & Li, 2020) for the details. To balance this divergence term and improve.

We end this section by summarizing the differences from (Qu & Li, 2020) and the reasons of the convergence rates improvement.

**Remark 9** As shown in Lemmas 2 and 3, we keep the Bregman divergence term \( D_f(x^k, y^k) \), and use a constant \( \tau \) to balance this divergence term and \( \|x^{k+1} - x^k\|^2 \). As shown in the proofs of Theorems 3 and 4, we make the constant before \( D_f(x^k, y^k) \) positive by setting \( \tau \) small. As a comparison, Qu & Li (2020) did not use this Bregman divergence term, and they bounded the term \( \|\bar{x}^k - y^k\|^2 \), which is generated by the consensus errors and is an analog to our term \( D_f(x^k, y^k) \) generated in (31), by setting much smaller step sizes than ours. See (32) and (53) in (Qu & Li, 2020) for the details. To make the constant \( A_4 \) in their (32) positive, Qu & Li (2020) set the step size of the order \( \alpha = \mathcal{O}\left(\frac{1}{L(r+\epsilon)}\right) \). Since \( \sqrt{\mu\alpha} \) dominates the convergence rate for strongly convex problems, Qu & Li (2020) only got the slower convergence rate of \( \mathcal{O}\left((1 - (\frac{L}{r})^{5/7})^k\right) \). For nonstrongly convex problems, Qu & Li (2020) set the step size of the order \( \mathcal{O}\left(\frac{1}{\sqrt{\mu\alpha}}\right) \) to bound the corresponding term in their (53), which gives the slower convergence rate of \( \mathcal{O}\left(\frac{1}{\sqrt{\mu\alpha}}\right) \).

As shown in Lemma 3, to bound the consensus errors, we construct a linear combination of the consensus errors such that it shrinks geometrically with an additional error term. As a comparison, Qu & Li (2020) used the linear system inequality,

\[
\frac{1}{(1-\theta)^{K+1}} \left( F(\bar{x}^{K+1}) - F(x^*) + \left(\frac{\theta^2}{2\alpha} + \frac{\mu\theta}{2}\right) \|x^{K+1} - x^*\|^2 \right)
\leq F(\bar{x}^K) - F(x^*) + \left(\frac{\theta^2}{2\alpha} + \frac{\mu\theta}{2}\right) \|x^0 - x^*\|^2 + \frac{4(1-\sigma)}{27mL(1 + \frac{1}{\tau})(1-\theta)} \|\Pi s^0\|^2
\]

Thus, we have the second conclusion and

\[
\frac{8\theta^2}{59mL} \sum_{r=0}^{K-1} \frac{\Phi^r}{(1-\theta)^{r+1}} \leq F(\bar{x}^0) - F(x^*) + \left(\frac{\theta^2}{2\alpha} + \frac{\mu\theta}{2}\right) \|x^0 - x^*\|^2 + \frac{4(1-\sigma)}{59mL(1-\theta)} \|\Pi s^0\|^2.
\]

It follows from (39) that

\[
\sum_{k=0}^{K} \frac{L}{2m(1-\theta)^{k+1}} \|\Pi s^k\|^2
\leq \frac{4(1-\sigma)}{27mL(1 + \frac{1}{\tau})(1-\theta)} \|\Pi s^0\|^2 + \frac{8\theta^2}{27mL(1 + \frac{1}{\tau})} \sum_{r=0}^{K-1} \frac{\Phi^r}{(1-\theta)^{r+1}}
\]

\[
= \frac{4(1-\sigma)}{59mL(1-\theta)} \|\Pi s^0\|^2 + \frac{8\theta^2}{59mL} \sum_{r=0}^{K-1} \frac{\Phi^r}{(1-\theta)^{r+1}}
\]

\[
\leq 2 \left( F(\bar{x}^0) - F(x^*) + \left(\frac{\theta^2}{2\alpha} + \frac{\mu\theta}{2}\right) \|x^0 - x^*\|^2 + \frac{4(1-\sigma)}{59mL(1-\theta)} \|\Pi s^0\|^2 \right).
\]

**Proof 6** Plugging (39) into (22) and using the definition of \( \Phi^r \) in (26), we have

\[
\frac{1}{(1-\theta)^{K+1}} \left( F(\bar{x}^{K+1}) - F(x^*) + \left(\frac{\theta^2}{2\alpha} + \frac{\mu\theta}{2}\right) \|x^{K+1} - x^*\|^2 \right)
\leq F(\bar{x}^0) - F(x^*) + \left(\frac{\theta^2}{2\alpha} + \frac{\mu\theta}{2}\right) \|x^0 - x^*\|^2 + \frac{4(1-\sigma)}{27mL(1 + \frac{1}{\tau})(1-\theta)} \|\Pi s^0\|^2
\]

Thus, we have the second conclusion.

We end this section by summarizing the differences from (Qu & Li, 2020) and the reasons of the convergence rates improvement.
which needs to upper bound the spectral radius of a system matrix and thus it is quite involved. See the proofs of Lemmas 7 and 13-15 in (Qu & Li, 2020). Our proof is much simpler than those in (Qu & Li, 2020), and it can be extended to the time-varying graphs in a unified framework.

3.3. Bounding the Consensus Errors over Time-varying Graphs

In this section, we consider algorithm (13a)-(13d) over time-varying graphs. Our analysis follows the same proof framework in the previous section for static graphs, but with more involved details. In the next lemma, we first give the analogy counterparts of (32)-(34).

Lemma 6 Suppose that Assumptions 1 and 3 hold with \( \mu \geq 0 \). Let the sequence \( \{ \theta_k \}_{k=0}^K \) satisfy \( \frac{\theta_k}{1-\theta_k} \leq \theta_{k+1} \leq \theta_k \leq 1 \). Then, we have for any \( k \geq \gamma - 1 \),

\[
\| \Pi s^{k+1} \|^2 \leq \frac{1 + \sigma_\gamma}{2} \| \Pi s^{k-\gamma + 1} \|^2 + \frac{2\gamma}{1 - \sigma_\gamma} \sum_{r=k-\gamma + 1}^k (\theta_r^2 \Phi^r + c_0 \theta_r^2 \| \Pi z^r \|^2 + c_0 \| \Pi x^r \|^2),
\]

(40)

\[
\| \Pi x^{k+1} \|^2 \leq \frac{1 + \sigma_\gamma}{2} \| \Pi x^{k-\gamma + 1} \|^2 + \frac{5.5\gamma}{1 - \sigma_\gamma} \sum_{r=k-\gamma + 2}^{k+1} \theta_r^2 \| \Pi z^r \|^2,
\]

(41)

\[
\theta_{k+1}^2 \| \Pi z^{k+1} \|^2 \leq \frac{1 + \sigma_\gamma}{2} \theta_{k+1}^2 \| \Pi z^{k-\gamma + 1} \|^2 + \frac{4\gamma}{1 - \sigma_\gamma} \sum_{r=k-\gamma + 1}^k (\mu^2 \sigma_\gamma^2 \| \Pi x^r \|^2 + \alpha^2 \| \Pi x^r \|^2),
\]

(42)

where we denote \( c_0 = 4L^2 (1 + \frac{1}{\tau}) \), and \( \tau \) and \( \Phi^r \) are defined in Lemma 3.

Proof 7 From (13b) and the definition of \( W^{k,\gamma} \) in (7), we have for any \( k \geq \gamma - 1 \),

\[
s^{k+1} = W^{k+1} s^k + \nabla f(y^{k+1}) - \nabla f(y^k)
\]

\[
= \left( \prod_{t=k-\gamma + 2}^{k+1} W^t \right) s^{k-\gamma + 1} + \sum_{r=k-\gamma + 1}^k \left( \prod_{t=r+1}^k W^{t+1} \right) (\nabla f(y^{r+1}) - \nabla f(y^r))
\]

\[
= W^{k+1,\gamma} s^{k-\gamma + 1} + \sum_{r=k-\gamma + 1}^k W^{k+1,k-r} (\nabla f(y^{r+1}) - \nabla f(y^r)),
\]

where we denote \( \prod_{t=k+1}^k W^{t+1} = I \). Multiplying both sides by \( \Pi \), using (9) and (10), it gives

\[
\| \Pi s^{k+1} \| \leq \sigma_\gamma \| \Pi s^{k-\gamma + 1} \| + \sum_{r=k-\gamma + 1}^k \| \nabla f(y^{r+1}) - \nabla f(y^r) \|.
\]

(43)

Similar to (32), squaring both sides of (43) yields

\[
\| \Pi s^{k+1} \|^2 \leq \frac{1 + \sigma_\gamma}{2} \| \Pi s^{k-\gamma + 1} \|^2 + \frac{2}{1 - \sigma_\gamma} \left( \sum_{r=k-\gamma + 1}^k \| \nabla f(y^{r+1}) - \nabla f(y^r) \| \right)^2
\]

\[
\leq \frac{1 + \sigma_\gamma}{2} \| \Pi s^{k-\gamma + 1} \|^2 + \frac{2\gamma}{1 - \sigma_\gamma} \sum_{r=k-\gamma + 1}^k \| \nabla f(y^{r+1}) - \nabla f(y^r) \|^2.
\]

(44)

From (31), we have (40). It follows from (13d) that

\[
x^{k+1} = (1 - \theta_k) W^k x^k + \theta_k z^{k+1}
\]

\[
= \left( \prod_{t=k-\gamma + 1}^k (1 - \theta_t) W^t \right) x^{k-\gamma + 1} + \sum_{t=k-\gamma + 1}^k \left( \prod_{r=t+1}^k (1 - \theta_r) W^r \right) \theta_r z^{r+1}
\]

\[
= W^{k,\gamma} x^{k-\gamma + 1} \prod_{t=k-\gamma + 1}^k (1 - \theta_t) + \sum_{r=k-\gamma + 1}^k W^{k,k-r} \theta_r z^{r+1} \prod_{t=r+1}^k (1 - \theta_t).
\]
Similar to (43) and (44), we also have

\[
\|\Pi x^{k+1}\| \leq \sigma_\gamma \|\Pi x^{k-\gamma+1}\| + \sum_{r=k-\gamma+1}^{k} \theta_r \|\Pi z^{r+1}\| = \sigma_\gamma \|\Pi x^{k-\gamma+1}\| + \sum_{r=k-\gamma+2}^{k+1} \theta_{r-1} \|\Pi z^r\|,
\]

and

\[
\|\Pi x^{k+1}\|^2 \leq \frac{1 + \sigma_\gamma}{2} \|\Pi x^{k-\gamma+1}\|^2 + \frac{2\gamma}{1 - \sigma_\gamma} \sum_{r=k-\gamma+2}^{k+1} \theta_{r-1}^2 \|\Pi z^r\|^2.
\]

Using \(\theta_{r-1} \leq 1.62\theta_r\), we obtain (41). Similarly, for (13c), we have

\[
z^{k+1} = \frac{\theta_k}{\theta_k + \mu_\alpha} W_k z^k + \frac{\mu_\alpha}{\theta_k + \mu_\alpha} W_k y^k - \frac{\alpha}{\theta_k + \mu_\alpha} s^k
\]

\[
= \frac{\theta_k (1 + \mu_\alpha)}{\theta_k + \mu_\alpha} W_t z^k + \frac{\mu_\alpha (1 - \theta_k)}{\theta_k + \mu_\alpha} W_t x^k - \frac{\alpha}{\theta_k + \mu_\alpha} s^k
\]

\[
= \left( \prod_{t=k-\gamma+1}^{k} \frac{\theta_t (1 + \mu_\alpha)}{\theta_t + \mu_\alpha} W^t \right) z^{k-\gamma+1}
\]

\[
+ \sum_{r=k-\gamma+1}^{k} \left( \prod_{t=r+1}^{k} \frac{\theta_t (1 + \mu_\alpha)}{\theta_t + \mu_\alpha} W^t \right) \left( \frac{\mu_\alpha (1 - \theta_r)}{\theta_r + \mu_\alpha} W^r x^r - \frac{\alpha}{\theta_r + \mu_\alpha} s^r \right) \prod_{t=r+1}^{k} \frac{\theta_t (1 + \mu_\alpha)}{\theta_t + \mu_\alpha},
\]

and

\[
\|\Pi z^{k+1}\| \leq \sigma_\gamma \|\Pi z^{k-\gamma+1}\| + \sum_{r=k-\gamma+1}^{k} \left( \frac{\mu_\alpha (1 - \theta_r)}{\theta_r + \mu_\alpha} \|\Pi x^r\| + \frac{\alpha}{\theta_r + \mu_\alpha} \|\Pi s^r\| \right)
\]

\[
\leq \sigma_\gamma \|\Pi z^{k-\gamma+1}\| + \sum_{r=k-\gamma+1}^{k} \left( \frac{\mu_\alpha}{\theta_r} \|\Pi x^r\| + \frac{\alpha}{\theta_r} \|\Pi s^r\| \right),
\]

where we use (13a) in \(\frac{\alpha}{\theta_k + \mu_\alpha} \leq 1\) with \(\theta_k \leq 1\) in \(b\). Similar to (44), squaring both sides yields

\[
\|\Pi z^{k+1}\|^2 \leq \frac{1 + \sigma_\gamma}{2} \|\Pi z^{k-\gamma+1}\|^2 + \frac{4\gamma}{1 - \sigma_\gamma} \sum_{r=k-\gamma+1}^{k} \left( \frac{\mu_\alpha^2}{\theta_r^2} \|\Pi x^r\|^2 + \frac{\alpha^2}{\theta_r^2} \|\Pi s^r\|^2 \right).
\]

Multiplying both sides by \(\theta_{k+1}^2\) and using the non-increasing of \(\{\theta_k\}\), it further gives (42)

Motivated by the proof of Lemma 3, we want to construct a linear combination of the consensus errors. However, due to the time-varying graphs and the \(\gamma\)-step joint spectrum property in Assumption 3, we see from (40)-(42) that they shrink every \(\gamma\) iterations, rather than every \(\gamma\) iteration. By exploiting the special structures in (40)-(42), we define the following quantities:

\[
\mathcal{M}_{s}^{k+\gamma} = \max_{r=k+1, \ldots, k+\gamma} \|\Pi s^r\|^2, \quad \mathcal{M}_{x}^{k+\gamma} = \max_{r=k+1, \ldots, k+\gamma} \|\Pi x^r\|^2,
\]

\[
\mathcal{M}_{y}^{k+\gamma} = \max_{r=k+1, \ldots, k+\gamma} \|\Pi y^r\|^2, \quad \mathcal{M}_{z}^{k+\gamma} = \max_{r=k+1, \ldots, k+\gamma} \theta_r^2 \|\Pi z^r\|^2.
\]
Motivated by (25), we define the following quantity in the form of summation, instead of the maximum, and we sum up to 

\[ S_{\phi}^{k+\gamma-1,\gamma} = \sum_{r=k}^{k+\gamma-1} \theta_r^2 \Phi^r. \]

The next lemma is an analogy counterpart of Lemma 3. Unlike the classical analysis relying on the small gain theorem (Nedić et al., 2017), which is unclear how to be used to the accelerated methods, and especially for nonstrongly convex problems, our main idea is to construct a linear combination of \( M_{s}^{k+\gamma,\gamma}, M_{x}^{k+\gamma,\gamma}, \) and \( M_{z}^{k+\gamma,\gamma} \) with carefully designed weights such that it shrinks geometrically with the additional error term \( S_{\phi}^{k+\gamma-1,\gamma} \), which is crucial to extend our analysis over static graphs to time-varying graphs in a unified framework, both for nonstrongly convex and strongly convex problems. Moreover, our proof technique to bound the consensus errors can be embedded into many algorithm frameworks, because it is separated from the analysis of the inexact accelerated gradient descent in Lemma 2.

**Lemma 7** Under the settings of Lemma 6, letting \( \alpha \leq \frac{(1-\sigma)^3}{3385L^2\gamma^3\sqrt{1+\frac{\gamma}{\rho}}} \), we have for any \( t \geq 0 \),

\[
\max \left\{ M_{s}^{(t+1)\gamma,\gamma}, M_{x}^{(t+1)\gamma,\gamma} \right\} \leq C_{3}\rho t^2 + C_{4} \sum_{s=0}^{(t+1)\gamma-1} \rho^{(t-1)\gamma-s} \theta_s^2 \Phi^s.
\]

(45)

where \( \rho = \sqrt{1-\frac{1-\sigma}{5}}, C_{3} = \left( \frac{(1-\sigma)^3}{162L^2\gamma^4(1+\frac{\gamma}{\rho})} M_{s}^{(t+1)\gamma} + \frac{4425}{(1-\sigma)^3} M_{z}^{(t+1)\gamma} + 2M_{x}^{(t+1)\gamma} \right), \) and \( C_{4} = \frac{(1-\sigma)^3}{38L^2\gamma(1+\frac{\gamma}{\rho})}. \)

**Proof 8** For any \( t \) satisfying \( k \leq t \leq k + \gamma - 1 \) with \( k \geq \gamma \), we can relax (40) to

\[
\|\Pi s^{t+1}\| = \frac{1}{2} \|\Pi s^{t-\gamma+1}\| + 2\gamma \sum_{r=t-\gamma+1}^{t} \left( \theta_r^2 \Phi^r + c_0 \theta_r^2 \|\Pi z^r\|^2 + c_0 \|\Pi x^r\|^2 \right)
\]

\[
\leq \frac{1}{2} \|\Pi s^{t-\gamma+1}\| + 2\gamma \sum_{r=t-\gamma+1}^{t} \left( \theta_r^2 \Phi^r + \frac{2\gamma}{1-\sigma_\gamma} \sum_{r=k-\gamma}^{k+\gamma} \left( c_0 \theta_r^2 \|\Pi z^r\|^2 + c_0 \|\Pi x^r\|^2 \right) \right)
\]

\[
\leq \frac{1}{2} \|\Pi s^{t-\gamma+1}\| + 2\gamma \left( S_{\phi}^{k-1,\gamma} + S_{\phi}^{k+\gamma-1,\gamma} \right)
\]

\[
+ \frac{2\gamma}{1-\sigma_\gamma} \left( c_0 M_{z}^{k,\gamma} + c_0 M_{z}^{k+\gamma,\gamma} + c_0 M_{x}^{k,\gamma} + c_0 M_{x}^{k+\gamma,\gamma} \right)
\]

\[
\leq \frac{1}{2} \|\Pi s^{t-\gamma+1}\| + 2\gamma \left( S_{\phi}^{k-1,\gamma} + S_{\phi}^{k+\gamma-1,\gamma} \right)
\]

\[
+ \frac{4\gamma^2}{1-\sigma_\gamma} \left( c_0 M_{z}^{k,\gamma} + c_0 M_{z}^{k+\gamma,\gamma} + c_0 M_{x}^{k,\gamma} + c_0 M_{x}^{k+\gamma,\gamma} \right).
\]

Taking the maximum over \( t = k, k + 1, \ldots, k + \gamma - 1 \) on both sides, we have

\[
M_{s}^{k+\gamma,\gamma} \leq \frac{1+\sigma_\gamma}{2} M_{s}^{k,\gamma} + \frac{2\gamma}{1-\sigma_\gamma} \left( S_{\phi}^{k-1,\gamma} + S_{\phi}^{k+\gamma-1,\gamma} \right)
\]

\[
+ \frac{4\gamma^2}{1-\sigma_\gamma} \left( c_0 M_{z}^{k,\gamma} + c_0 M_{z}^{k+\gamma,\gamma} + c_0 M_{x}^{k,\gamma} + c_0 M_{x}^{k+\gamma,\gamma} \right).
\]

Similarly, for (42) and (41), we also have

\[
M_{z}^{k+\gamma,\gamma} \leq \frac{1+\sigma_\gamma}{2} M_{z}^{k,\gamma} + \frac{8\gamma^2}{1-\sigma_\gamma} \left( \mu_2^2 \sigma_\gamma^2 M_{z}^{k,\gamma} + \mu_2^2 \sigma_\gamma^2 M_{x}^{k+\gamma,\gamma} + \alpha^2 M_{s}^{k,\gamma} + \alpha^2 M_{z}^{k+\gamma,\gamma} \right),
\]

\[
M_{x}^{k+\gamma,\gamma} \leq \frac{1+\sigma_\gamma}{2} M_{x}^{k,\gamma} + \frac{11\gamma^2}{1-\sigma_\gamma} \left( M_{z}^{k,\gamma} + M_{z}^{k+\gamma,\gamma} \right),
\]

where for the second one, the relaxation of \( \sum_{r=k-\gamma+2}^{t} \theta_r^2 \|\Pi z^r\|^2 \leq \sum_{r=k-\gamma+1}^{t} \theta_r^2 \|\Pi z^r\|^2 \) also holds for any \( t \) satisfying \( k \leq t \leq k + \gamma - 1 \).
Adding the above three inequalities together with weights \(c_1\), \(c_2\), and \(c_3\) respectively, we have

\[
c_1 M_s^{k+\gamma,\gamma} + c_2 M_x^{k+\gamma,\gamma} + c_3 M_x^{k+\gamma,\gamma} \\
\leq \frac{8c_2 \gamma^2 \alpha^2}{1 - \sigma_\gamma} M_x^{k+\gamma,\gamma} + \left( \frac{4c_1 c_0 \gamma^2}{1 - \sigma_\gamma} + \frac{11c_3 \gamma^2}{1 - \sigma_\gamma} \right) M_x^{k+\gamma,\gamma} + \frac{8c_2 \gamma^2 \alpha^2}{1 - \sigma_\gamma} M_x^{k+\gamma,\gamma} \\
\quad + \left( \frac{c_1 (1 + \sigma_\gamma)}{2} + \frac{8c_2 \gamma^2 \alpha^2}{1 - \sigma_\gamma} \right) M_x^{k+\gamma,\gamma} + \left( \frac{c_2 (1 + \sigma_\gamma)}{2} + \frac{8c_1 c_0 \gamma^2}{1 - \sigma_\gamma} + \frac{11c_3 \gamma^2}{1 - \sigma_\gamma} \right) M_x^{k+\gamma,\gamma} \\
\quad + \left( \frac{c_3 (1 + \sigma_\gamma)}{2} + \frac{8c_2 \gamma^2 \alpha^2}{1 - \sigma_\gamma} \right) M_x^{k+\gamma,\gamma} + \frac{2c_1 \gamma}{1 - \sigma_\gamma} \left( S_{\phi}^{k-1,\gamma} + S_{\phi}^{k+\gamma-1,\gamma} \right).
\]

We want to choose \(c_1\), \(c_2\), \(c_3\), and \(\alpha\) such that the following inequalities hold,

\[
\frac{8c_2 \gamma^2 \alpha^2}{1 - \sigma_\gamma} \leq \frac{c_1 (1 - \sigma_\gamma)}{20}, \quad \frac{c_1 (1 + \sigma_\gamma)}{2} + \frac{8c_2 \gamma^2 \alpha^2}{1 - \sigma_\gamma} \leq \frac{c_1 (3 + \sigma_\gamma)}{4},
\]

\[
\frac{4c_1 c_0 \gamma^2}{1 - \sigma_\gamma} + \frac{11c_3 \gamma^2}{1 - \sigma_\gamma} \leq \frac{c_2 (1 - \sigma_\gamma)}{20}, \quad \frac{c_2 (1 + \sigma_\gamma)}{2} + \frac{4c_1 c_0 \gamma^2}{1 - \sigma_\gamma} + \frac{11c_3 \gamma^2}{1 - \sigma_\gamma} \leq \frac{c_2 (3 + \sigma_\gamma)}{4},
\]

\[
\frac{4c_1 c_0 \gamma^2}{1 - \sigma_\gamma} + \frac{8c_2 \gamma^2 \alpha^2}{1 - \sigma_\gamma} \leq \frac{c_3 (1 - \sigma_\gamma)}{20}, \quad \frac{c_3 (1 + \sigma_\gamma)}{2} + \frac{4c_1 c_0 \gamma^2}{1 - \sigma_\gamma} + \frac{8c_2 \gamma^2 \alpha^2}{1 - \sigma_\gamma} \leq \frac{c_3 (3 + \sigma_\gamma)}{4},
\]

which are satisfied if the three inequalities in the left column hold. Accordingly, we can choose \(c_3 = \frac{81c_1 c_0 \gamma^2}{(1 - \sigma_\gamma)^2}\), \(c_2 = \frac{17900c_1 c_0 \gamma^2}{(1 - \sigma_\gamma)^2} + \frac{220c_1 c_0 \gamma^2}{(1 - \sigma_\gamma)^2}\), and \(\alpha^2 \leq \min \left\{ \frac{(1 - \sigma_\gamma)^2}{2864000c_0 \gamma^2}, \frac{(1 - \sigma_\gamma)^2}{2864000c_0 \gamma^2} \right\}\). Thus, we have for any \(k \geq \gamma\),

\[
\frac{19 + \sigma_\gamma}{20} \left( c_1 M_s^{k+\gamma,\gamma} + c_2 M_x^{k+\gamma,\gamma} + c_3 M_x^{k+\gamma,\gamma} \right) \\
\leq \frac{3 + \sigma_\gamma}{4} \left( c_1 M_s^{k,\gamma} + c_2 M_x^{k,\gamma} + c_3 M_x^{k,\gamma} \right) + \frac{2c_1 \gamma}{1 - \sigma_\gamma} \left( S_{\phi}^{k-1,\gamma} + S_{\phi}^{k+\gamma-1,\gamma} \right) \\
\leq \frac{19 + \sigma_\gamma}{20} \left( 1 - \frac{1 - \sigma_\gamma}{5} \right) \left( c_1 M_s^{k,\gamma} + c_2 M_x^{k,\gamma} + c_3 M_x^{k,\gamma} \right) + \frac{2c_1 \gamma}{1 - \sigma_\gamma} \left( S_{\phi}^{k-1,\gamma} + S_{\phi}^{k+\gamma-1,\gamma} \right),
\]

and

\[
c_1 M_{s,x}^{(t+1)r+\gamma,\gamma} + c_2 M_{x,z}^{(t+1)r+\gamma,\gamma} + c_3 M_{x,x}^{(t+1)r+\gamma,\gamma} \\
\leq \left( 1 - \frac{1 - \sigma_\gamma}{5} \right)^t \left( c_1 M_{s,x}^{t,\gamma,\gamma} + c_2 M_{x,z}^{t,\gamma,\gamma} + c_3 M_{x,x}^{t,\gamma,\gamma} \right) \\
+ \frac{40c_1 \gamma}{19(1 - \sigma_\gamma)} \sum_{r=1}^t \left( 1 - \frac{1 - \sigma_\gamma}{5} \right)^{t-r} \left( S_{\phi}^{r-1,\gamma} + S_{\phi}^{(r+1)\gamma-1,\gamma} \right). \quad (46)
\]

It follows from (27) and \(c_2 > c_3\) that

\[
\frac{c_2}{2} \max \left\{ M_{s,x}^{(t+1)r+\gamma,\gamma}, M_{x,x}^{(t+1)r+\gamma,\gamma} \right\} \leq c_1 M_{s,x}^{(t+1)r+\gamma,\gamma} + c_2 M_{x,z}^{(t+1)r+\gamma,\gamma} + c_3 M_{x,x}^{(t+1)r+\gamma,\gamma}.
\]
On the other hand, denoting \( \rho = \sqrt{1 - \frac{\gamma}{s}} \), we have
\[
\sum_{r=1}^{t} \rho^{(t-r)} \left( S_{\phi}^{\gamma-1, \gamma} + S_{\phi}^{(r+1)\gamma-1, \gamma} \right)
= \rho^t \sum_{r=1}^{t} \left( \frac{1}{\rho^t} \right)^r \left( \sum_{s=(r-1)\gamma}^{r\gamma-1} \theta_s^2 \Phi_s^s + \sum_{s=r\gamma}^{(r+1)\gamma-1} \theta_s^2 \Phi_s^s \right)
= \rho^t \sum_{s=0}^{(t-1)\gamma} \left( \frac{1}{\rho^t} \right)^{(t-1)\gamma-s} \theta_s^2 \Phi_s^s
\]
where \( \Phi_s^s \) is defined in Lemma 3, and \( \alpha = \sum_{s=0}^{(t-1)\gamma} \theta_s^2 \Phi_s^s \) is defined in Lemma 7.

Plugging the above two inequalities and the settings of \( c_3 \) and \( c_0 \) into (46), we have the conclusion.

**Remark 10** We briefly demonstrate the advantage of introducing the quantities of \( M_{s}^{k+\gamma, \gamma}, M_{s}^{k+\gamma, \gamma}, M_{s}^{k+\gamma, \gamma}, \) and \( M_{s}^{k+\gamma, \gamma} \). As discussed in Remark 9, researchers in the control community often use linear system inequality to prove the convergence, which is quite challenging to use over time-varying graphs. For example, Saadatniaki et al. (2020) constructed a \( \gamma \)th order linear system inequality in the form of
\[
\begin{pmatrix}
O^{k+\gamma} \\
O^{k+\gamma-1} \\
O^{k+\gamma-2} \\
\vdots \\
O^{k+1}
\end{pmatrix}
\begin{pmatrix}
M_1 & M_2 & \cdots & M_{\gamma-1} & M_{\gamma} \\
I & I & & & \\
& I & & & \\
& & \ddots & & \\
& & & I & \\
& & & & I
\end{pmatrix}
\begin{pmatrix}
O^{k+\gamma-1} \\
O^{k+\gamma-2} \\
O^{k+\gamma-3} \\
\vdots \\
O^{k}
\end{pmatrix}
\]

for the AB/push-pull method, which is an extension of gradient tracking to time-varying directed graphs. They only proved that the spectral radius of the system matrix is strictly less than 1 without any explicit upper bound. Thus, no explicit convergence rate was given in (Saadatniaki et al., 2020).

On the other hand, the system (47) can be simplified by defining similar quantities of \( M_{s}^{k+\gamma, \gamma}, M_{s}^{k+\gamma, \gamma}, M_{s}^{k+\gamma, \gamma}, \) and \( M_{s}^{k+\gamma, \gamma} \). Moreover, the proof can be further simplified by avoiding analyzing the spectral radius if our technical trick of constructing the linear combination is used.

Following the same proof framework over static graphs, our next step is to bound the weighted cumulative consensus errors. However, the details are much more complex. The proof of Lemma 4 provides some insights.

**Lemma 8** Suppose that Assumptions 1 and 3 hold with \( \mu = 0 \). Let the sequence \( \{\theta_k\}_{k=0}^{T} \) satisfy \( 1 - \frac{\theta_k}{\theta_k} = \frac{1}{\sigma_{k-1}} \) with \( \theta_0 = 1 \), let \( \alpha = \frac{(1-\sigma)^3}{3385L\gamma^2 \sqrt{1 + \frac{\gamma}{s}}} \). Then for algorithm (13a)-(13d), we have
\[
\max\left\{ \sum_{k=0}^{T} \frac{L}{2m\theta_k^2} \|H \|^2, \sum_{k=0}^{T} \frac{L}{2m\theta_k^2} \|P \|^2 \right\}
\leq \frac{235\gamma^3 C_3 L}{m(1-\sigma)^3} + \frac{10\gamma^2}{mL(1 + \frac{\gamma}{s})(1-\sigma)^2} \sum_{s=0}^{T-\gamma-1} \Phi_s^s
\]
where \( \tau \) and \( \Phi^s \) are defined in Lemma 3, and \( C_3 \) is defined in Lemma 7.

**Proof 9** We first verify \( \theta_k \leq 1.62 \theta_{k+1} \) for all \( k \geq 0 \), which is required in Lemmas 6 and 7. In fact, from \( 1 - \frac{\theta_{k+1}}{\theta_k} = \frac{1}{\sigma_k} \) and \( \theta_0 = 1 \), we have \( \theta_{k+1}/\theta_k \leq (1, 1.62) \in (1, 1.62) \) for any \( k \geq 0 \). Next, we upper and lower bound \( \rho \). From the
definition of \( \rho = \sqrt{1 - \frac{1-\sigma_2}{3}} \) and the fact that \((1 - \frac{1}{\gamma})^\gamma \geq 1 - x \) for any \( x \in (0, 1) \) and \( \gamma \geq 1 \), we know

\[
\rho \leq 1 - \frac{1 - \sigma_2}{5\gamma}, \quad \rho^\gamma \geq \frac{4}{5}.
\]  

(49)

The remaining proof is similar to that of Lemma 4. From the definition of \( M^{(t+1)\gamma + \gamma}_{\gamma} \) and (45), we have

\[
\sum_{k=1}^{T} \frac{L}{2m\theta_k^2} \|\Pi y^k\|^2 = \sum_{t=0}^{T-1} \sum_{r=1}^{\gamma} \frac{L}{2m\theta_{t+r}^2} \|\Pi y^{t+r}\|^2 \leq \sum_{t=0}^{T-1} \sum_{r=1}^{\gamma} \frac{L}{2m\theta_{t+r}^2} M^{(t+1)\gamma}_{\gamma}
\]

\[
\leq \sum_{t=0}^{T-1} \sum_{r=1}^{\gamma} \frac{C_3 L \rho^\gamma}{2m\theta_{t+r}^2} + \sum_{t=0}^{T-1} \sum_{r=1}^{\gamma} \frac{C_4 L}{2m\theta_{t+r}^2} \sum_{s=0}^{(t+1)\gamma - 1} \rho^{(t+1)\gamma} \rho^s \Phi
\]

\[
\leq \frac{C_3 L}{2m} \sum_{t=0}^{T-1} \sum_{r=1}^{\gamma} \rho^\gamma \rho^s \Phi + \frac{C_4 L}{2m} \sum_{t=0}^{T-1} \sum_{r=1}^{\gamma} \rho^s \rho^\gamma \Phi
\]

\[
= \frac{C_3 L}{2m\rho^\gamma} \sum_{k=1}^{T\gamma} \rho^k \sum_{s=0}^{\gamma - 1} \rho^s \Phi
\]

(50)

where \((t+1)\gamma - 1 = \lceil \frac{t\gamma}{1} \rceil \gamma - 1 \in \mathbb{Z} \) comes from the variable substitution \( k = t\gamma + r \) with \( r = 1, 2, \ldots, \gamma \). Next, we compute the second part in \( \mathbb{B} \). It gives

\[
\sum_{k=1}^{T\gamma} \rho^k \sum_{s=0}^{\gamma - 1} \rho^s \Phi
\]

\[
\leq \sum_{k=1}^{T\gamma} \rho^k \sum_{s=0}^{\gamma - 1} \rho^s \Phi
\]

(51)

Plugging (51) into (50), it follows from \( \Pi y^0 = 0 \) that

\[
\sum_{k=0}^{T\gamma} \frac{L}{2m\theta_k^2} \|\Pi y^k\|^2
\]

\[
\leq \frac{C_3 L}{2m\rho^\gamma} \sum_{k=1}^{T\gamma} \rho^k \sum_{s=0}^{\gamma - 1} \rho^s \Phi
\]

\[
\leq \frac{C_3 L}{2m\rho^\gamma} \sum_{k=1}^{T\gamma} \rho^k \sum_{s=0}^{\gamma - 1} \rho^s \Phi
\]

(1 - \rho)^3

\[
\leq \frac{C_3 L}{2m\rho^\gamma} \sum_{k=1}^{T\gamma} \rho^k \sum_{s=0}^{\gamma - 1} \rho^s \Phi
\]

(1 - \rho)^3 \theta_{s-\gamma}^2
From the settings of $\theta$, the next lemma is an analogy counterpart of Lemma 5, and the proof is similar to that of the above Lemma 8.

Lemma 7. Replacing $\max \|\|\Pi y^k\|\|$ by $\|\|\Pi x^k\|\|$ in the above analysis, we have the same bound for $\|\|\Pi x^k\|\|$. The next lemma is an analogy counterpart of Lemma 5, and the proof is similar to that of the above Lemma 8.

**Lemma 9** Suppose that Assumptions 1 and 3 hold with $\mu > 0$. Let $\alpha \leq \frac{(1-\sigma_\gamma)^3}{3385L\gamma^4\sqrt{1+\gamma}}$ and $\theta_k \equiv \theta = \sqrt{\frac{\rho}{2}}$. Then for algorithm (13a)-(13d), we have

$$\max \left\{ \sum_{k=0}^{T\gamma} \frac{L}{2m(1-\theta)^{k+1}} \|\Pi y^k\|^2 : \sum_{k=0}^{T\gamma} \frac{L}{2m(1-\theta)^{k+1}} \|\Pi x^k\|^2 \right\} \leq \frac{3C_3L\gamma}{m(1-\theta)(1-\sigma_\gamma)} + \frac{\theta^2}{7mL(1+\frac{1}{r})} \sum_{s=0}^{T\gamma-1} \frac{\Phi^s}{(1-\theta)^{s+1}}$$

where $\tau$ and $\Phi^s$ are defined in Lemma 3, and $C_3$ is defined in Lemma 7.

**Proof 10** From the definition of $\mathcal{M}^{(t+1)\gamma,\gamma}$ and (45), we have

$$\sum_{k=0}^{T\gamma} \frac{L}{2m(1-\theta)^{k+1}} \|\Pi y^k\|^2 \leq \sum_{t=0}^{T-1} \frac{L}{2m(1-\theta)^{t+1}} \|\Pi y^{t+1}\|^2 \leq \sum_{t=0}^{T-1} \frac{L}{2m(1-\theta)^{t+1}} \mathcal{M}^{(t+1)\gamma,\gamma} \leq \sum_{t=0}^{T-1} \frac{C_3L\rho^\gamma}{2m(1-\theta)^{t+1}} + \sum_{t=0}^{T-1} \frac{C_4L}{2m(1-\theta)^{t+1}} \sum_{s=0}^{t-1} \frac{\rho^s}{\rho^{t-1}} \Phi^s \leq \sum_{t=0}^{T-1} \frac{C_3L}{2m(1-\theta)^{t+1}} \sum_{s=0}^{t-1} \frac{\rho^s}{\rho^{t-1}} \Phi^s$$

Similar to (51), we have

$$\sum_{k=1}^{T\gamma} \left( \frac{\rho}{1-\theta} \right)^k \frac{\Phi^s}{\rho^s} \leq \sum_{s=0}^{\gamma-1} \frac{\Phi^s}{\rho^s} \sum_{k=1}^{T\gamma} \left( \frac{\rho}{1-\theta} \right)^k + \sum_{s=0}^{T\gamma-1} \frac{\Phi^s}{\rho^s} \sum_{k=s+\gamma+1}^{T\gamma} \left( \frac{\rho}{1-\theta} \right)^k.$$

From the settings of $\theta$ and $\alpha$, we know $\theta \leq \frac{1-\sigma_\gamma}{1-\theta}$. From (49), we further have $\frac{\rho}{1-\theta} < 1$ and $1 - \rho - \theta \geq \frac{0.19(1-\sigma_\gamma)}{\gamma}$. So we
have \( \sum_{k=r+1}^{K} \left( \frac{\rho}{1-\vartheta} \right)^k \leq \left( \frac{\rho}{1-\vartheta} \right)^r \). It follows from \( \| \Pi y^0 \| = 0 \) that

\[
\sum_{k=0}^{T \gamma} \frac{L}{2m(1-\theta)^{k+1}} \| \Pi y^k \|^2 \leq \frac{C_3 L}{2m \rho^{\gamma-1}(1-\theta)(1-\rho)} \\
\quad + \frac{C_4 L \theta^2}{2m \rho^{2\gamma-1}(1-\theta)(1-\rho)} \left( \sum_{s=0}^{\gamma-1} \frac{(1-\theta)^s}{(1-\rho)^s} \right)^{-\gamma} \sum_{s=\gamma}^{T \gamma-1} \frac{(1-\theta)^s}{(1-\rho)^s} \\
\leq \frac{C_3 L}{2m \rho^{\gamma-1}(1-\theta)(1-\rho)} + \frac{C_4 L \theta^2(1-\theta) \gamma}{2m \rho^{3\gamma-1}(1-\rho)} \sum_{s=0}^{T \gamma-1} \frac{(1-\theta)^s}{(1-\rho)^s+1} \\
\leq \frac{3.3 C_3 L \gamma}{m(1-\theta)(1-\rho)} + \frac{\theta^2}{7mL(1+\frac{1}{\tau})} \sum_{s=0}^{T \gamma-1} \frac{(1-\theta)^s}{(1-\rho)^s+1},
\]

where \( \frac{\theta}{\rho} \geq 1 \) such that \( \left( \frac{1-\theta}{\rho} \right)^s \leq \left( \frac{1-\theta}{\rho} \right)^\gamma \) for all \( s \leq \gamma - 1 \) \( \leq \) uses (49), \( 1 - \rho - \theta \geq \frac{0.19(1-\rho)}{\gamma} \), and the definition of \( C_4 \) given in Lemma 7. Replacing \( \| \Pi y^k \| \) by \( \| \Pi x^k \| \) in the above analysis, we have the same bound for \( \| \Pi x^k \| ^2 \).

Now, we are ready to prove Theorems 1 and 2. We first prove Theorem 1.

**Proof 11** Plugging (48) into (21) and using the definition of \( \Phi^r \) in (26), we have

\[
\frac{F(x^{T+1}) - F(x^*)}{\theta^2 T \gamma} + \frac{1}{2\alpha} \| x^{T+1} - x^* \|^2 \\
\leq \frac{1}{2\alpha} \| x^0 - x^* \|^2 + \frac{235 \gamma^3 C_3 L}{m(1-\sigma_\gamma)^3} \sum_{k=0}^{T \gamma} \left( \frac{1}{2\alpha} \frac{L}{2} \frac{20 L \gamma^2}{(1-\sigma_\gamma)^2} \right) \| x^{t+1} - x^t \|^2 \\
\quad + \frac{1}{2\alpha} \frac{L}{(1+\frac{\tau}{\theta})} \left( \frac{1-20(1+\tau) \gamma^2}{(1+\frac{1}{\theta})(1-\sigma_\gamma)^2} \right) D_f(x^k, y^k) \\
\leq \frac{1}{2\alpha} \| x^0 - x^* \|^2 + \frac{235 \gamma^3 C_3 L}{m(1-\sigma_\gamma)^3} \sum_{k=0}^{T \gamma} \left( \frac{1}{4\alpha} \| x^{t+1} - x^t \|^2 + \frac{1}{2\alpha} \frac{L}{(1+\frac{1}{\theta})} \right) D_f(x^k, y^k) \\
\leq \frac{1}{2\alpha} \| x^0 - x^* \|^2 + \frac{235 \gamma^3 C_3 L}{m(1-\sigma_\gamma)^3} - \frac{1}{5mL} \sum_{r=0}^{T \gamma-1} \Phi^r,
\]

where in \( \leq \) we let \( \tau = \frac{(1-\sigma_\gamma)^2}{4\alpha^2} \) so to have \( \frac{20(1+\tau) \gamma^2}{(1+\frac{1}{\theta})(1-\sigma_\gamma)^2} = \frac{1}{2} \). \( \alpha = \frac{(1-\sigma_\gamma)^4}{2187 L \gamma^2} \leq \frac{(1-\sigma_\gamma)^3}{3385 L \gamma^3 \sqrt{1+\frac{1}{\theta}}} \), and \( \frac{1}{4\alpha} \geq \frac{L}{2} + \frac{20 L \gamma^2}{(1-\sigma_\gamma)^2} \). So we have

\[
F(x^{T+1}) - F(x^*) \leq \frac{\theta^2 T \gamma}{2\alpha} \left( \frac{1}{2\alpha} \| x^0 - x^* \|^2 + \frac{235 \gamma^3 C_3 L}{m(1-\sigma_\gamma)^3} \right),
\]

\[
\frac{1}{5mL} \sum_{r=0}^{T \gamma-1} \Phi^r \leq \frac{1}{2\alpha} \| x^0 - x^* \|^2 + \frac{235 \gamma^3 C_3 L}{m(1-\sigma_\gamma)^3}.
\]
It follows from (48) that

\[
\max \left\{ \sum_{k=0}^{T_\gamma} \frac{L}{2m\theta_k} \|\Pi y^k\|^2, \sum_{k=0}^{T_\gamma} \frac{L}{2m\theta_k} \|\Pi x^k\|^2 \right\} \\
\leq \frac{235\gamma^3 C_3 L}{m(1-\sigma_\gamma)^3} + \frac{10\gamma^2}{mL(1+\frac{5}{2})(1-\sigma_\gamma)^2} \sum_{s=0}^{T_\gamma-1} \Phi^s \\
\leq \frac{235\gamma^3 C_3 L}{m(1-\sigma_\gamma)^3} + \frac{1}{4mL} \sum_{s=0}^{T_\gamma-1} \Phi^s \\
\leq \frac{9}{4} \left( \frac{1}{2\alpha} \|z^0-x^*\|^2 + \frac{235\gamma^3 C_3 L}{m(1-\sigma_\gamma)^3} \right).
\]

(56)

From the definition of \(C_3\) given in Lemma 7, we have

\[
\frac{1}{2\alpha} \|z^0-x^*\|^2 + \frac{235\gamma^3 C_3 L}{m(1-\sigma_\gamma)^3} \\
\leq \frac{1}{2\alpha} \|z^0-x^*\|^2 + \frac{1}{27mL^2} M^2_{\gamma,x} + \frac{103870\gamma^5}{m(1-\sigma_\gamma)^3} M^2_{\gamma,x} + \frac{470\gamma^3}{m(1-\sigma_\gamma)^3} \Phi_{\gamma,x} \equiv C_5.
\]

(57)

The conclusion follows from Lemma 10.

The next lemma gives a sharper bound of the constant \(C_5\) appeared in the above proof.

**Lemma 10** Under the settings of Theorem 1, we can further bound \(C_5\) by

\[
C_5 \leq \frac{1}{2\alpha} \|z^0-x^*\|^2 + \frac{1}{20mL^2} \max_{r=0,...,\gamma} \|\Pi s^r\|^2.
\]

(58)

**Proof 12** From step (13c) with \(\mu = 0\), we have for any \(k \leq \gamma - 1\),

\[
\theta_{k+1} \|\Pi z^{k+1}\| \leq \theta_k \|\Pi z^{k+1}\| \leq \theta_k \|\Pi z^k\| + \alpha \|\Pi s^k\| \\
\leq \theta_0 \|\Pi z^0\| + \alpha \sum_{t=0}^{k} \|\Pi s^t\| \leq \alpha \sum_{t=0}^{\gamma-1} \|\Pi s^t\|
\]

where we use \(\Pi z^0 = 0\). Squaring both sides gives

\[
\theta_{k+1}^2 \|\Pi z^{k+1}\|^2 \leq \alpha^2 \gamma \sum_{t=0}^{\gamma-1} \|\Pi s^t\|^2 \leq \alpha^2 \gamma^2 \max_{r=0,...,\gamma} \|\Pi s^r\|^2.
\]

From the setting of \(\alpha\) and the definition of \(M^2_{\gamma,x}\), we have

\[
\frac{103870\gamma^5}{m(1-\sigma_\gamma)^3} M^2_{\gamma,x} \leq \frac{1}{4523mL^2} \max_{r=0,...,\gamma} \|\Pi s^r\|^2.
\]

On the other hand, it follows from step (13d) that

\[
\|\Pi x^{k+1}\| \leq \theta_k \|\Pi z^{k+1}\| + \|\Pi x^k\| \leq \sum_{t=0}^{k} \theta_t \|\Pi z^{t+1}\| \leq 1.62 \sum_{t=0}^{\gamma-1} \theta_{t+1} \|\Pi z^{t+1}\|.
\]

Squaring both sides gives

\[
\|\Pi x^{k+1}\|^2 \leq 2.63\gamma \sum_{t=0}^{\gamma-1} \theta_{t+1}^2 \|\Pi z^{t+1}\|^2 \leq 2.63\gamma^4 \alpha^2 \max_{r=0,...,\gamma} \|\Pi s^r\|^2.
\]
From the setting of $\alpha$ and the definition of $M^\gamma_x$, we have
\[
\frac{470L\gamma^3}{m(1-\sigma_\gamma)^3} M^\gamma_x \leq \frac{1-\sigma_\gamma}{380070mL\gamma} \max_{r=0,\ldots,\gamma} \|\Pi s^r\|^2.
\]
So we have the conclusion.

In the next lemma, we measure the convergence rate at $x_{(i)}^{t+1}$ for any $i = 1, \ldots, m$.

**Lemma 11** Under the settings of Theorem 1, we have for any $t \leq T - 1$,
\[
F(x_{(i)}^{t+1}) - F(x^*) \leq \frac{1}{(t+1)^2} \max \left\{ \frac{\sqrt{m}(1-\sigma_\gamma)}{Lo\gamma}, 8m \right\} \left( \frac{2}{\alpha} \|\pi^0 - x^*\|^2 + \frac{1-\sigma_\gamma}{5mL\gamma} \max_{r=0,\ldots,\gamma} \|\Pi s^r\|^2 \right).
\]

**Proof 13** We first bound $F(x_{(i)}^k) - F(\pi^k)$ for any $i$. From Lemma 1, we have
\[
F(x_{(i)}^k) \leq f(y_{(i)}^{k-1}, y^{k-1}) + \frac{L}{2} \|x_{(i)}^k - y_{(i)}^{k-1}\|^2 + \frac{L}{2m} \|\Pi y_{(i)}^{k-1}\|^2
\]
\[
\leq F(\pi^k) + \frac{\|x_{(i)}^k - \pi^k\|^2}{\alpha} + L\|x_{(i)}^k - \pi^k\|^2 + \frac{L}{2m} \|\Pi y_{(i)}^{k-1}\|^2
\]
\[
\leq a \frac{\|x_{(i)}^k - \pi^k\|^2}{\alpha} + \frac{\|x_{(i)}^k - \pi^k\|^2}{\alpha} \|\Pi x_{(i)}^k\|^2 + \frac{L\|x_{(i)}^k - \pi^k\|^2}{2m} \|\Pi y_{(i)}^{k-1}\|^2,
\]
where we use (15c) with $\mu = 0$, (15a), and (15d) in $\leq$. From the definition of $\Phi^\tau$ in (26), it follows from (55) that for any $k \leq T\gamma$,
\[
\|\pi^k - \pi^{k-1}\|^2 \leq \frac{\Phi^{k-1}}{2mL(1+\frac{1}{\gamma})} \leq \frac{5(1-\sigma_\gamma)^2}{80L\gamma^2} \left( \frac{2}{\alpha} \|\pi^0 - x^*\|^2 + \frac{235\gamma^3 C_3 L}{m(1-\sigma_\gamma)^3} \right),
\]
where $\leq$ uses the setting of $\tau = \frac{1-(1-\sigma_\gamma)^2}{4\gamma}$ given in the proof of Theorem 1. From (54) and (56), we have for any $t\gamma + 1$ with $t \leq T - 1$
\[
F(x_{(i)}^{t+1}) - F(x^*) \leq \frac{\theta t^2}{\alpha} \max \left\{ \frac{\sqrt{m}(1-\sigma_\gamma)}{Lo\gamma}, 8m \right\} \left( \frac{1}{2\alpha} \|\pi^0 - x^*\|^2 + \frac{235\gamma^3 C_3 L}{m(1-\sigma_\gamma)^3} \right).
\]
From (57), (58), and (36), we have the conclusion.

Next, we prove Theorem 2.

**Proof 14** Plugging (53) into (22) and using the definition of $\Phi^\tau$ in (26), we have
\[
\frac{1}{(1-\theta)^{T\gamma+1}} \left( F(\pi^{T\gamma+1}) - F(x^*) + \left( \frac{\theta^2}{2\alpha} + \frac{\mu\theta}{2} \right) \|\pi^{T\gamma+1} - x^*\|^2 \right)
\]
\[
\leq F(\pi^0) - F(x^*) + \left( \frac{\theta^2}{2\alpha} + \frac{\mu\theta}{2} \right) \|\pi^0 - x^*\|^2 + \frac{3.3C_3 L\gamma}{m(1-\theta)(1-\sigma_\gamma)}
\]
\[
- \sum_{k=0}^{T\gamma} \left( \frac{1}{(1-\theta)^k} \left( 1 - \frac{2}{7} \frac{(1+\tau)}{1+\frac{1}{\gamma}} \right) D_f(\pi^k, y^k) + \frac{1}{(1-\theta)^{k+1}} \left( \frac{\theta^2}{2\alpha} - \frac{L\theta^2}{2} - \frac{2L\theta^2}{7} \right) \|\pi^{k+1} - \pi^k\|^2 \right)
\]
\[
\leq F(\pi^0) - F(x^*) + \left( \frac{\theta^2}{2\alpha} + \frac{\mu\theta}{2} \right) \|\pi^0 - x^*\|^2 + \frac{3.3C_3 L\gamma}{m(1-\theta)(1-\sigma_\gamma)}
\]
\[
- \sum_{k=0}^{T\gamma} \left( \frac{1}{2(1-\theta)^k} D_f(\pi^k, y^k) + \frac{\theta^2}{4\alpha(1-\theta)^{k+1}} \|\pi^{k+1} - \pi^k\|^2 \right)
\]
\[
\leq F(\pi^0) - F(x^*) + \left( \frac{\theta^2}{2\alpha} + \frac{\mu\theta}{2} \right) \|\pi^0 - x^*\|^2 + \frac{3.3C_3 L\gamma}{m(1-\theta)(1-\sigma_\gamma)} - \frac{\theta^2}{11mL} \sum_{r=0}^{T\gamma-1} \Phi^r \frac{\theta r^2}{(1-\theta)^{r+1}}.
\]
Thus, we have the second conclusion by plugging the definition of $C$ where at each iteration, $m$

whence in $\leq$ we let $\tau = \frac{\theta}{L}$ so to have $\frac{2(1+\tau)}{\tau(1+\frac{1}{2})} = \frac{1}{2}$, $\alpha = \frac{(1-\sigma)^3}{4244L\gamma^2} \leq \frac{(1-\sigma)^3}{385L\gamma^2 \sqrt{1+\frac{1}{\tau}}}$, and $\frac{1}{4\alpha} \geq \frac{L}{2} + 2L$. Thus, we have the first conclusion and

$$
\frac{\theta^2}{11mL} \sum_{r=0}^{T\gamma-1} \frac{\Phi_r}{(1-\theta)^{r+1}} \leq F(\mathbf{x}^0) - F(x^*) + \left( \frac{\theta^2}{2\alpha} + \frac{\mu \theta}{2} \right) \|\mathbf{x}^0 - x^*\|^2 + \frac{3.3C_3L\gamma}{m(1-\theta)(1-\sigma_\gamma)}.
$$

It follows from (53) that

$$
\sum_{k=0}^{T\gamma} \frac{L}{2m(1-\theta)^{k+1}} \|\Pi_k\|^2 \leq \frac{3.3C_3L\gamma}{m(1-\theta)(1-\sigma_\gamma)} + \frac{\theta^2}{7mL(1+\frac{1}{2})} \sum_{s=0}^{T\gamma-1} \frac{\Phi^s}{(1-\theta)^{s+1}} \\
\leq 2 \left( F(\mathbf{x}^0) - F(x^*) + \left( \frac{\theta^2}{2\alpha} + \frac{\mu \theta}{2} \right) \|\mathbf{x}^0 - x^*\|^2 + \frac{3.3C_3L\gamma}{m(1-\theta)(1-\sigma_\gamma)} \right).
$$

Thus, we have the second conclusion by plugging the definition of $C_3$ in Lemma 7.

Remark 11 We rewrite the convergence rates in Theorems 1 and 2 in the form of complexities. For the nonstrongly convex case, letting $F(\mathbf{x}^{T\gamma+1}) - F(x^*) \leq \frac{C_3L}{\mu(1-\sigma_\gamma)^2} = \epsilon$, we have $T_{\gamma} + 1 = \frac{\sqrt{2C}}{\epsilon} = \mathcal{O}(\frac{\sqrt{T}}{\epsilon}).$ Each iteration only requires $\mathcal{O}(1)$ communication round and gradient oracle call. For the strongly convex case, letting $F(\mathbf{x}^{T\gamma+1}) - F(x^*) \leq (1-\theta)^{T\gamma+1}C = \epsilon$, we have $T_{\gamma} + 1 = \mathcal{O}(\frac{\log \sqrt{T}}{\epsilon}) = \mathcal{O}(\frac{1}{(1-\sigma_\gamma)^{1.5}} \sqrt{\frac{T}{\epsilon} \log \frac{1}{\epsilon}}).

4. Numerical Experiments

In this section, we test the performance of the accelerated gradient tracking (Acc-GT) over time-varying graphs. The performance of Acc-GT over static graphs has already been verified in (Qu & Li, 2020). Moreover, Qu & Li (2020) reported in their experiment that algorithm (12a)-(12d) with fixed step size (our theoretical setting) performs faster than the one with vanishing step sizes (their theoretical setting). We tune the step sizes $\gamma, \sigma$ for Acc-GT and Acc-GT-C, respectively. When $\gamma, \sigma$ are designed for directed graphs. We use the Metropolis gossip matrix given in (8).

For strongly convex problem, we compare Acc-GT and Acc-GT-C (Acc-GT with multiple consensus) with DIGing (Nedić et al., 2017), DAGD-C (Rogozin et al., 2021b), as well as the classical non-distributed accelerated gradient descent (AGD), where AGD runs on a single machine, and it gives the upper limit of the practical performance of the distributed algorithms. We do not compare with the time-varying $\hat{A}B$-push-pull method (Saadatniaki et al., 2020) and the push-sum based methods (Nedić & Olshevsky, 2016; 2015; Nedić et al., 2017) because they are designed for directed graphs. We tune the step sizes $\alpha = \frac{0.1}{T}$ for Acc-GT and Acc-GT-C, $\alpha = \frac{0.2}{T}$ for DIGing, and $\alpha = \frac{1}{T}$ for AGD. For DAGD-C, when $d = 2$, we test on the number of inner iterations $sa T = \frac{\sigma}{\sigma(1-\sigma_\gamma)} \approx 201$ and $T = \frac{\gamma}{(1-\sigma_\gamma)} \approx 302$, and name the methods DAGD-C1 and DAGD-C2, respectively. When $d = 20$, we test on $T = \frac{\gamma}{(1-\sigma_\gamma)} \approx 14$ and $T = \frac{\gamma}{(1-\sigma_\gamma)} \approx 17$, respectively. For Acc-GT-C,
we set the number of inner iterations as \( T = \frac{\gamma}{50(1-\sigma_p)} \approx 12 \) and \( T = \frac{\gamma}{10(1-\sigma_p)} \approx 7 \) for \( d = 2 \) and \( d = 20 \), respectively. The other parameter settings follow the corresponding theorems of each method. For nonstrongly convex problem, we compare Acc-GT and Acc-GT-C with DIGing (Nedić et al., 2017), APM (Li et al., 2020a), and AGD, and set the same step sizes as above. We tune the step size \( \alpha = \frac{1}{2} \) for APM, and set the number of inner iterations as \( T_k = \frac{\gamma \log(k+1)}{100(1-\sigma_p)} \) and \( T_k = \frac{\gamma \log(k+1)}{100(1-\sigma_p)} \) at each outer iteration for \( d = 2 \) and \( d = 20 \), respectively. Although the convergence of DIGing was only proved for strongly convex problem in (Nedić et al., 2017), it also converges for nonstrongly convex ones by using our proof techniques.

Figures 1-4 plot the results, where the objective function error is measured by \( F(x^k) - F(x^*) \), and the consensus error is measured by \( \sqrt{\sum_{i=1}^m \| x_i^k - x^* \|^2 } \). Since \( F(x^*) \) is unknown, we approximate it by the output of the classical non-distributed AGD with 50000 iterations for strongly convex problem, and 200000 iterations for nonstrongly convex one. One round of communications means that all the nodes, if they are active, receive information from their neighbors once, and one round of gradient computations means that all the nodes compute their gradient \( \nabla f(x) \) once in parallel. Especially, for AGD, one round of gradient computations means computing the full gradient \( \sum_{i=1}^m \nabla f_i(x) \) once. We have the following observations:

1. Acc-GT converges faster than DIGing, both on the decrease of the objective function errors and consensus errors. This verifies the efficiency of the acceleration technique. Moreover, for strongly convex problem, Acc-CT is only three times slower than the classical non-distributed AGD.

2. Acc-GT-C needs more communication rounds than Acc-GT to reach the same precision of the objective function error, although Acc-GT-C has lower theoretically communication round complexity. Thus, Acc-GT-C is only for the theoretical interest, and it is not suggested in practice.

3. DAGD-C and APM need less gradient computation rounds than Acc-GT to reach the same precision of the objective function error, but they require more communication rounds. This supports that the multiple consensus subroutine places more communication burdens in practice. But on the other hand, DAGD-C and APM have almost the same computation cost as the classical non-distributed AGD. Comparing DAGD-C1 with DAGD-C2, we see that less inner iterations give larger consensus errors, and our settings of the inner iteration numbers are fair to DAGD-C.

4. The network connectivity, that is, the different settings of \( d \) in our experiment, has little influence on the decrease of the objective function errors for both DIGing and Acc-GT.\(^3\) We think this is because we set the same step sizes for \( d = 2 \) and \( d = 20 \). From Theorems 1 and 2, we see that the network connectivity constants impact on the step sizes, and the step sizes impact on the decrease speed of the objective function errors. On the other hand, from the proofs of Theorems 1 and 2, we see that the decrease speed of the consensus errors given in the two theorems is not tight, and we observe in the experiment that the consensus errors decrease faster when \( d = 20 \) for both DIGing and Acc-GT.

5. Conclusion

This paper extends the widely used accelerated gradient tracking to time-varying network, which was originally proposed in (Qu & Li, 2020) only for static network. We prove the state-of-the-art complexities for both nonstrongly convex and strongly convex problems with the optimal dependence on the precision \( \epsilon \) and the condition number \( L/\mu \), matching that of the classical centralized accelerated gradient descent. When the network is static, our complexities improve significantly over the previous ones proved in (Qu & Li, 2020). When combing with the Chebyshev acceleration, Our complexities exactly match the lower bounds for both nonstrongly convex and strongly convex problems over static graphs.

This paper only considers the \( \gamma \)-connectivity of time-varying graphs. Some researchers formulate the time-varying graphs as random graphs (Hong & Chang, 2017; Jakovetić et al., 2014b; Ananduta et al., 2020) and use the mean connectivity in expectation. It is an interesting future work to extend our proof techniques to random graphs. Another interesting direction is to study the acceleration over time-varying unbalanced directed graphs (Nedić et al., 2017). Besides gradient tracking,\(^3\) This phenomenon depends on the data. We also test on the simulated data with \( p = 100 \), \( n = 50 \), and \( m = 1000 \), where each element of the feature vectors is generated randomly in \([0, 1]\) from the uniform distribution, we observe that Acc-GT with \( d = 20 \) performs about 1.1 times as fast as that with \( d = 2 \). The difference is not significant.
Figure 1. Comparisons of the objective function errors (left) and consensus errors (right) with respect to the number of communication (top) and computation (bottom) rounds for strongly convex problem with $d = 2$. 
Figure 2. Comparisons of the objective function errors (left) and consensus errors (right) with respect to the number of communication (top) and computation (bottom) rounds for strongly convex problem with $d = 20$. 
Figure 3. Comparisons of the objective function errors (left) and consensus errors (right) with respect to the number of communication (top) and computation (bottom) rounds for nonstrongly convex problem with $d = 2$. 
Figure 4. Comparisons of the objective function errors (left) and consensus errors (right) with respect to the number of communication (top) and computation (bottom) rounds for nonstrongly convex problem with $d = 20$. 
A. Proof of Lemma 1

**Proof 15** From the $\mu$-strong convexity and $L$-smoothness of $f_i$, we have

\[
F(w) = \frac{1}{m} \sum_{i=1}^{m} f_i(y_i) \geq \frac{1}{m} \sum_{i=1}^{m} \left( f_i(y_i^k) + \left\langle \nabla f_i(y_i^k), w - y_i^k \right\rangle + \frac{\mu}{2} \|w - y_i^k\|^2 \right)
\]

\[
= \frac{1}{m} \sum_{i=1}^{m} \left( f_i(y_i^k) + \left\langle \nabla f_i(y_i^k), w - y_i^k \right\rangle + \frac{\mu}{2} \|w - \bar{y}^k\|^2 + \mu \left\langle w - \bar{y}^k, \bar{y}^k - y_i^k \right\rangle \right)
\]

\[
= \frac{1}{m} \sum_{i=1}^{m} \left( f_i(y_i^k) + \left\langle \nabla f_i(y_i^k), w - y_i^k \right\rangle + \frac{\mu}{2} \|w - \bar{y}^k\|^2 + \frac{\mu}{2} \|y_i^k - y_i^k\|^2 \right)
\]

\[
\geq \frac{1}{m} \sum_{i=1}^{m} \left( f_i(y_i^k) + \left\langle \nabla f_i(y_i^k), w - y_i^k \right\rangle + \frac{\mu}{2} \|w - \bar{y}^k\|^2 \right)
\]

\[
\overset{b}{=} f(\bar{y}^k, y^k) + \left\langle \bar{y}^k, w - \bar{y}^k \right\rangle + \frac{\mu}{2} \|w - \bar{y}^k\|^2,
\]

and

\[
F(w) \leq \frac{1}{m} \sum_{i=1}^{m} \left( f_i(y_i^k) + \left\langle \nabla f_i(y_i^k), w - y_i^k \right\rangle + \frac{L}{2} \|w - y_i^k\|^2 \right)
\]

\[
= \frac{1}{m} \sum_{i=1}^{m} \left( f_i(y_i^k) + \left\langle \nabla f_i(y_i^k), w - y_i^k \right\rangle + \frac{L}{2} \|w - \bar{y}^k\|^2 + \frac{L}{2} \|\bar{y}^k - y_i^k\|^2 \right)
\]

\[
= \frac{1}{m} \sum_{i=1}^{m} \left( f_i(y_i^k) + \left\langle \nabla f_i(y_i^k), w - y_i^k \right\rangle + \frac{L}{2} \|w - \bar{y}^k\|^2 + \frac{L}{2} \|y_i^k - y_i^k\|^2 \right)
\]

\[
= f(\bar{y}^k, y^k) + \left\langle \bar{y}^k, w - \bar{y}^k \right\rangle + \frac{L}{2} \|w - \bar{y}^k\|^2 + \frac{L}{2m} \|\Pi y^k\|^2,
\]

where $\overset{=}{a}$ and $\overset{=}{c}$ use the definition of $\bar{y}^k$ in (3), $\overset{=}{b}$ and $\overset{=}{d}$ use the definition of $f(\bar{y}^k, y^k)$ in (17), (16), and the definition of $\Pi y$ in (4).
