**ARTICLE DETAILS**

**ABSTRACT**

The aim of the study was to evaluate the level of knowledge of university students about risk factors, signs and symptoms, and impact of diabetes in Punjab, Pakistan. A cross-sectional study design was used for this study. Population of the study was students who were enrolled in public and private universities in Punjab. A multistage sampling method was used for this study. Total 1260 students were selected randomly among which 1087 respondents completed the self-administered questionnaire. Descriptive statistics and the Chi-square test were used through Statistical Package of Social Science (SPSS) version 20.0. The results of the study showed that 544 (50%) respondents were females, most respondents 617 (56.7%) were between 20-23 years old, 589 (54.2%) respondents were studying at undergraduate level, 435 (40%) respondents had poor economic status, 1006 (92.5%) respondents were single, 813 (4.8%) respondents never got their sugar level checked, and 696 (64%) respondents had family history of diabetes. Findings of the study also indicated that most of the respondents 77.9% had inadequate knowledge about risk factors of type 2 diabetes, 73.4% respondents had inadequate knowledge of signs and symptoms of type 2 diabetes, and 72.2% respondents had inadequate knowledge of impact of diabetes. Chi-square test showed that level of knowledge of diabetes was associated with gender ($p < .001$), education ($p < .001$), marital status ($p < .001$), ever checking of sugar ($p < .001$), and family history of diabetes ($p < .001$). The study concluded that majority of the respondents had inadequate knowledge of diabetes. Therefore, there is a need of educational programs and awareness sessions for university students. It will be helpful in enhancing students’ knowledge and reducing the prevalence of diabetes in the future of Pakistan.

1. Introduction

Diabetes is prevailing rapidly worldwide. Almost one person is developing diabetes in every five seconds (Alberti, Zimmet, & Shaw, 2007; Federation, 2011). The rate of increase of diabetes is 170% in developing countries and 47% in developed countries (Wild, Roglic, Green, Sicree, & King, 2004). In the world, it is estimated that 463 million people are living with diabetes. It is predicted that by 2045 diabetic patients will be more than 700 million.

The recent National Diabetes Survey (NDSP 2016-17) shows the prevalence of diabetes in Pakistan. According to NDSP, the prevalence of diabetes is 26.3% in Pakistan (Basit, Fawwad, Qureshi, & Shera, 2018). The provincial pattern of prevalence is as follows: Punjab; 30.2%, Khyber Pakhtunkhwa; 13.2%, Balochistan; 29.5% and Sindh; 32.3%. These figures equate to approximately 27.4 million people aged 20 and above, based on the 207.77 million total population (Basit, Fawwad, & Baqa, 2019; Basit et al., 2018). If the present situation continues, Pakistan is expected to achieve the highest prevalence of diabetes globally (Hussain & Ali, 2016).

There are many risk factors of diabetes and they are differentiated on the basis of modifiable factors and nonmodifiable risk factor. Nonmodifiable factors include gender, ethnicity, aging, family history of diabetes (Abate & Chandalia, 2003; Gale & Gillespie, 2001; Valdez, Yoon, Liu, & Khoury, 2007). As compared to females, males are more prone to develop T2D and its related complications (Gale & Gillespie, 2001). Earlier studies have mentioned that ethnic groups like South Asians, Africans, and Americans face the burden of type 2 diabetes and more risk of onset of type 2 diabetes as compared to the European (Abate & Chandalia, 2001; Chow, Foster, Gonzalez, & McIver, 2012).

Nonmodifiable factors include obesity (Engelgau, Narayan, & Herman, 2000), high abdomen fat (Lee, Bacha, & Arslanian, 2006), unhealthy diet (Alneami & Coleman, 2016), physical inactivity and sedentary lifestyle (Association, 2021), poor sleep quality (Gitu, 2018), skipping breakfast (Ballon, Neuenschwander, & Schlesinger, 2019), low consumption of vegetables and fruits (Li, Fan, Zhang, Hou, & Tang, 2014; Villegas et al., 2008), high blood pressure (M.-J. Kim, Lim, Choi, & Park, 2015), more consumption of sweet products (Khatib, 2004), more salt intake (Radzeviciene & Ostrauskas, 2017), stress (Harris et al., 2017; Pouwer, Kupper, & Adriaanse, 2010), smoking (Health & Services, 2014), high alcohol consumption (Kao, Padvey, Boland, Watson, & Brancati, 2001), impaired glucose tolerance (Nathan et al., 2007), low birth weight (Jornayvaz et al., 2016), high cholesterol level (Seo et al., 2011; Wada, Yano, Hamano, Nabika, & Kumakura, 2016), fried and fast food consumption (Panagiotakos et al., 2005), and pregnancy (C. Kim, Newton, & Knopp, 2002).

The most common signs and symptoms among diabetic patients are weight loss, feeling thrust, frequent urination, blurred vision, numbness in hands and feet, weakness, decrease sexual ability (Ramachandran, 2014). The diabetic patients have more changes of complications like cardiovascular disease, retinopathy, nephropathy, neuropathy, blood pressure, infections, reduce life expectancy, and liver problems (Nathan, 1993).

According to World Health Organization, Diabetes is considered a non-communicable disease with a growing prevalence worldwide (Asif, 2014) and will become the leading cause of death globally (Mathers & Loncar, 2006). Type 2 diabetes (T2D) affects the most productive life span, but it also begins to appear in young age (Al-Mahrooqi et al., 2013). T2D is now increasingly being diagnosed in young adults, but it is a disease that can be prevented through adopting positive health behaviors and drug therapy (Duncan, 2006; Ramkumar & Tandon, 2013; Sridhar, Putcha, & Lakshmi, 2010). Positive health behaviors including physical activity and healthy food choice play a vital role in the control and
prevention of T2D, and is associated with lower risk of T2D (Dunkley et al., 2014; Mongiello, Freudenberg, Jones, & Spark, 2016). Knowledge forms the foundation for the acceptance of positive health behaviors and these behaviors changes at the time of young adults enable them to be protected from disease throughout their lives (Katulanda et al., 2011; N. Khan, Gomathi, Shehnaz, & Muttappallymyalil, 2012). Therefore, it is important that young adults are well informed about preventive measures for T2D, its onset risk factors, signs and symptoms and its impact.

Most of the studies have been conducted in Pakistan to measure the level of knowledge or awareness among general population as well as diabetic patients (Gillani et al., 2018; R. M. A. Khan, CH, & Ahmad, 2009; Mangi et al., 2018; Masood, Saleem, Hassan, Zia, & Khan, 2016; Shahzad et al., 2018; ur Rehman et al., 2014; Zuhaid, Zahir, & Diju, 2012) expect for a few studies conducted among medical students about assessment of knowledge of diabetes (Khosa, Mukhtar Mehoob, Sana, & Khosa; Phil & Hafeez, 2016). Unfortunately, diabetes knowledge regarding risk factors of type 2 diabetes, signs and symptoms of diabetes and impact of diabetes are not well documented among university students in Pakistan. Therefore, this study has been conducted to evaluate the diabetes knowledge among university students in Punjab, Pakistan.

2. Materials and Methods

The cross-sectional study was conducted among university students in Punjab, Pakistan from October 2019 to December 2019. The respondents were selected by multistage sampling technique. At first stage, three of nine divisions of Punjab province were randomly sampled (i.e. Lahore, Faisalabad, and Multan). At second stage, three public universities (i.e. University of the Punjab Lahore, Government College University Faisalabad, and Bahauddin Zakariya University Multan) and three private universities (University of Lahore, University of Faisalabad, and Institute of Southern Punjab Multan) were sampled from each selected division. At third stage, three faculties were sampled from each selected university (i.e. Faculty of Arts and Social Science, Faculty of Natural Science, and Faculty of Management Sciences). At fourth stage, about 70 students were randomly sampled in each selected faculty of the selected public and private universities. Finally, a total of 1260 university students were randomly selected for the study. Out of them, 173 did not completely fill the questionnaire. After elimination of the unfilled questionnaire, total 1087 respondents’ data were used for analysis.

3.1 Data Collection

A structured self-administered online questionnaire with closed-ended questions about risk factors of type 2 diabetes having 24-items (see table 2), signs and symptoms having 11-items (see table 3) and impact of diabetes having 8-items (see table 4) were developed after extensive literature review. The questions responses were “don’t know”, “no”, and “yes”. If the respondents reported incorrect answer, then their score was coded ‘0’ and if they reported correct answer then their score was coded ‘1’. In diabetes knowledge questionnaire some statements of the questions were negatively stated (e.g. feeling less thirst). Demographic characteristics of the respondents including gender, age groups, level of education, economic status, marital status, ever checked sugar level, and family history of diabetes (see table 1). The questionnaire was pretested with a group of 120 university students to identify problems if any, related to questions, words and statements. Next that identified inaccuracies and inconsistences were revised. The reliability of the total diabetes knowledge questionnaire score was assessed by Cronbach’s alpha with a value of 0.85 in this research study. Face validity of the questionnaire was checked by two experts, one medical sociologist and one diabetologist and they recommended some changes and the researcher incorporated it.

The research study is the part of PhD research project that was approved from the Doctoral Programme Coordination Committee, University of the Punjab Lahore, Pakistan for ethical clearance.
Review of Education, Administration and Law (REAL) Vol. 4, (3) 2021, 675-688

(Reference letter no 6777-ACAD dated 12-09-2019). At the start of the questionnaire, the researcher gave the consent form and detail of the study objective. Every individual had the right to accept it or reject it. Those individuals who accepted it they further continued the questionnaire. Privacy and confidentiality of the respondents were ensured by the researcher by not asking questions regarding their names, contact numbers, addresses.

3.2 Data Analysis
The objective of the study was to evaluate the level of knowledge about diabetes and its association with demographic characteristics of the respondents. Therefore, frequencies, percentages and Chi-square test was applied through SPSS version 20.0 and p < 0.5 was considered statistically significant.

4. Results
In all, 544 (50%) males and 543 (50%) were in the data analysis. The results indicated that most respondents 617 (56.7%) were between 20-23 years old, 589 (54.2%) respondents were studying at undergraduate level, 435 (40%) respondents had poor economic status, 1006 (92.5%) respondents were single, 813 (4.8%) respondents never got their sugar level checked, and 696 (64%) respondents had family history of diabetes (Table 1).

| Table 1: Demographic Characteristics of the participants (n = 1087) |
|---------------------------------------------------------------|
| Variables          | Total | Percentage |
|-------------------|-------|------------|
| Gender            |       |            |
| Male              | 544   | 50         |
| Female            | 543   | 50         |
| Age               |       |            |
| Less than 20      | 324   | 29.8       |
| 20 - 23           | 617   | 56.7       |
| 24 - 29           | 146   | 13.5       |
| Education         |       |            |
| Intermediate      | 314   | 28.8       |
| Undergraduate     | 589   | 54.2       |
| Graduate          | 137   | 12.6       |
| M.Phil./PhD       | 47    | 4.4        |
| Economic Status   |       |            |
| Poor              | 435   | 40         |
| Middle            | 425   | 39         |
| Rich              | 227   | 21         |
| Marital Status    |       |            |
| Single            | 1006  | 92.5       |
| Married           | 81    | 7.5        |
| Ever Check Blood Sugar |     |            |
| No                | 813   | 74.8       |
| Yes               | 274   | 25.2       |
| Family History of Diabetes | |         |
| No                | 696   | 64         |
| Yes               | 391   | 36         |
Majority of respondents incorrectly reported about knowledge of risk factors of T2D and they did not know that being Asian, more abdomen fat, less physical activity, sleep less than 7-8 hours, aging, poor dietary patterns 2-3 serving of fruits, pregnancy, impaired glucose tolerance, low birth weight were risk factors of T2D onset. On the other side, most of the respondents reported correctly that gender (male), overweight or obesity, high blood pressure, more sweets products intake, sedentary lifestyle, used more salt, stress, smoking and alcohol use, breakfast skipping, high cholesterol level and more intake of fast food were the risk factors of T2D (Table 2).

**Table 2: Responses of Participants Regarding Knowledge of Risk Factors of Type 2 Diabetes**

| Sr. | Statements                                         | Incorrect responses | Correct responses |
|-----|----------------------------------------------------|---------------------|-------------------|
| 1   | Males have more risk of onset of Type II diabetes than females. | 319 (29.3)         | 768 (70.7)        |
| 2   | The Asian have high risk of onset of Type II diabetes. | 983 (90.4)         | 104 (9.6)         |
| 3   | A person who is obese or overweight has more chances of onset of Type II diabetes. | 15 (1.4)           | 1072 (98.6)       |
| 4   | A person who has diabetic patients in his family has more chance of risks of onset of Type II diabetes. | 955 (87.9)         | 132 (12.1)        |
| 5   | A person who has blood pressure more than 140/90 mmHg has more risk of onset of Type II diabetes. | 417 (38.4)         | 670 (61.6)        |
| 6   | A person who has more abdominal fat has more risk of onset of Type II diabetes. | 973 (89.5)         | 114 (10.5)        |
| 7   | A person who consumes more sweets products has more chance of risk of onset of Type II diabetes. | 17 (1.6)           | 1070 (98.4)       |
| 8   | A person who is doing less physical activity or do no exercise has more risk of onset of Type II diabetes. | 625 (57.5)         | 462 (42.5)        |
| 9   | A person who has not sedentary lifestyle has less risk of onset of Type II diabetes. | 422 (38.8)         | 665 (61.2)        |
| 10 | A person who sleeps less than 7-8 hours has high risk of onset of Type II diabetes. | 791 (82.8) | 296 (27.2) |
| 11 | A person whose age is increasing has high risk of onset of Type II diabetes. | 883 (81.2) | 204 (18.8) |
| 12 | A person who has poor dietary pattern (eating more oily food, fats, soft drinks etc.) has high risk of onset of Type II diabetes. | 613 (56.4) | 474 (43.6) |
| 13 | A person who intakes or uses more salt (>5g) in his meals has high risk of onset of Type II diabetes. | 308 (28.3) | 779 (71.7) |
| 14 | A person who eats 2-3 serving of vegetables daily has less chance of onset of type II diabetes. | 932 (85.7) | 155 (14.3) |
| 15 | A person who eats 2-3 serving of fruits daily has less chance of onset of type II diabetes. | 549 (50.5) | 538 (49.5) |
| 16 | A married woman who has diabetes during pregnancy has more risk of onset of Type II diabetes in the future. | 977 (89.9) | 110 (10.1) |
| 17 | A person who faces more stress has high risk of onset of Type II diabetes. | 407 (37.4) | 680 (62.6) |
| 18 | A person who smokes regularly has high risk of onset of Type II diabetes. | 409 (37.6) | 678 (62.4) |
| 19 | A person who drinks more alcohol has high risk of onset of Type II diabetes. | 471 (43.3) | 616 (56.7) |
| 20 | A person who does not take breakfast regularly has more risk of onset of Type II diabetes. | 524 (48.2) | 563 (51.8) |
| 21 | A person who has impaired glucose tolerance has high risk of onset of Type II diabetes. | 959 (88.2) | 128 (11.8) |
| 22 | A person who has low birth weight has high risk of onset of type II diabetes in the future. | 918 (84.5) | 169 (15.5) |
| 23 | A person who has high cholesterol level has high risk of onset of Type II diabetes. | 526 (48.4) | 561 (51.6) |
| 24 | A person who eats fast food (pizza, burger, sandwich, chicken nuggets, french fries etc) has high risk of onset of Type II diabetes. | 439 (40.4) | 649 (59.6) |
Knowledge about sign and symptoms of T2D among respondents were poor. More than 50% of the respondents incorrectly answered on the questions- weight gain, less feeling of thirst ad hunger, blurred vision, rapid healing of wounds, numbness in hands and feet, skin infection and decrease sexual ability. They did not consider them signs and symptoms of T2D (Table 3).

| Sr. | Statements                        | Incorrect responses | Correct responses |
|-----|-----------------------------------|---------------------|-------------------|
| 1   | Weight gain                       | 859 (79)            | 228 (21)          |
| 2   | Less insulin production           | 520 (47.8)          | 567 (52.2)        |
| 3   | Less urination                    | 641 (59)            | 446 (41)          |
| 4   | Less feeling of thirst            | 700 (64.4)          | 387 (35.6)        |
| 5   | Less feeling of hunger            | 647 (59.5)          | 440 (40.5)        |
| 6   | Blurred vision                    | 663 (61)            | 424 (39)          |
| 7   | Rapid healing of wound            | 575 (52.9)          | 512 (47.1)        |
| 8   | Numbness in hands and feet        | 586 (53.9)          | 501 (46.1)        |
| 9   | Feeling of weakness               | 379 (34.9)          | 708 (65.1)        |
| 10  | Skin infection                    | 606 (55.7)          | 481 (44.3)        |
| 11  | Decrease sexual ability           | 712 (65.5)          | 375 (34.5)        |

The knowledge of impact of diabetes on diabetic patients was also less among the respondents and they did not consider eye problems, kidney problems, brain problems and liver problems as complications of diabetes (Table 4).
The level of knowledge of risk factors showed that only 22% respondents had adequate knowledge of T2D. The level of knowledge of signs and symptoms of diabetes showed that one fourth (26.6%) respondents had adequate knowledge of T2D. Lastly, level of knowledge of impact of diabetes highlighted that 27.8% respondents had adequate knowledge of diabetes (Figure 1).

| Sr. | Statements                  | Incorrect responses | Correct responses |
|-----|-----------------------------|---------------------|-------------------|
| 1   | Eye problems                | 586 (53.9)          | 501 (46.1)        |
| 2   | Kidney problems             | 578 (53.2)          | 509 (46.8)        |
| 3   | Heart problems              | 532 (48.9)          | 555 (51.1)        |
| 4   | Brain problems              | 739 (68)            | 348 (32)          |
| 5   | Blood pressure              | 432 (39.7)          | 655 (60.3)        |
| 6   | Liver problems              | 882 (81.1)          | 205 (18.9)        |
| 7   | Infections                  | 426 (39.2)          | 661 (60.8)        |
| 8   | Reduce life expectancy      | 539 (49.6)          | 548 (50.4)        |

**Table 4:** Responses of Participants Regarding Impact of Diabetes

The level of knowledge of risk factors showed that only 22% respondents had adequate knowledge of T2D. The level of knowledge of signs and symptoms of diabetes showed that one fourth (26.6%) respondents had adequate knowledge of T2D. Lastly, level of knowledge of impact of diabetes highlighted that 27.8% respondents had adequate knowledge of diabetes (Figure 1).

**Figure 1** Percentage of Level of Knowledge of Diabetes
Chi-square test showed that level of knowledge of diabetes was significantly associated with gender (p < .001), education (p < .001), marital status (p < .001), ever checking of blood sugar (p < .001), and family history of diabetes (p < .001) (Table 5).

| Variables                     | Inadequate Knowledge f (%) | Adequate Knowledge f (%) | Chi square |
|-------------------------------|-----------------------------|--------------------------|------------|
| Gender                        |                             |                          | 14.7***    |
| Male                          | 388 (71.3)                  | 156 (28.7)               |            |
| Female                        | 441 (81.2)                  | 102 (18.8)               |            |
| Age (years)                   |                             |                          | 3.7        |
| Less than 20                  | 245 (75.6)                  | 79 (24.4)                |            |
| 20 – 23                       | 481 (78)                    | 136 (22)                 |            |
| 24 -29                        | 103 (70.5)                  | 43 (29.5)                |            |

5. Discussion

The findings of the study showed that university students had inadequate knowledge about T2D diabetes with the frequencies of correct answers being less than 50% in the following areas: its risk factors like family history of diabetes, abdominal fat, less physical activity, sleep less than 7-8 hours, aging, poor dietary patterns, and daily vegetable consumption; its signs and symptoms like less feeling of thirst, blurred vision, numbness in hands and feet, decreased sexual ability; and its impact like eye problems, brain problems, kidney problems. In addition, demographic characteristics of the university students like gender was significantly associated with level of knowledge about diabetes and in it males had higher knowledge than females. Studies conducted in Pakistan and other countries also showed the same finding that males had more diabetes knowledge than females (Soltanian, Bahreini, & Afkhami-Ardekani, 2007; ur Rehman et al., 2014).

Level of education of the respondents was statistically significantly associated with level of diabetes knowledge. And the respondents who had higher education were more aware about the diabetes risk factors, sign and symptoms and its impacts. The previous studies supported this finding that the people with more educated have higher level of knowledge about diabetes (Foma, Saidu, Omoleke, & Jafali, 2013; Soltanian et al., 2007; Ulvi et al., 2009). Age group of the respondents did not significant association with level of knowledge of diabetes but the finding showed that respondents between 23-29 years old were more aware about diabetes risk factors but their percentage was very low. A study conducted in Pakistan had the same finding and showed that respondents having age more than 20 years had adequate knowledge of diabetes (Masood et al., 2016).

Economic status of the respondents was not associated with level of knowledge in this study. The previous study mentioned that individuals who belonged to higher income group had more diabetes knowledge score as compared to low-income group individuals (Masood et al., 2016; Sabri, Qayyum, Saigol, Zafar, & Aslam, 2007). Furthermore, it might be due to lack of seriousness and perceived susceptibility of the disease among this age group. It was observed that marital status of the respondents was associated with level of knowledge and respondents who were married had higher level of knowledge of diabetes. The finding of the study was aligned with the study conducted on university students in Saudi Arabia that marital status of the students were statistically associated with level of knowledge of diabetes (Alamri, 2021).

The current study as well as earlier studies revealed that family history of diabetes was significantly associated with level of knowledge of diabetes among university students (Amankwah-Poku, 2019; N. Khan et al., 2012). The study findings also indicated that mostly students reported that family history was not a risk factor of diabetes onset. It might be due to no family member with diabetes and that’s why they had low knowledge of diabetes and risk perception as compared to students who had family history of diabetes (Mongiello et al., 2016).

The findings also indicated that the level of knowledge of diabetes was associated with ever blood sugar. The respondents who ever checked blood sugar had higher knowledge of T2D as compared to respondents who did not ever check blood sugar. A study conducted on university students mentioned that students who checked blood sugar had more diabetes knowledge score (Gazzaz, 2020). Earlier study showed that poor knowledge about T2D among the young adults was common, so efforts to decrease the frequency of T2D must include young adults who are at susceptible age and can be inspired to adopt positive health behaviors (Al-Mahrooqi et al., 2013). It was observed that lack of knowledge about diabetes was one of many factors which had made the T2D burden worse.
From the last two decades, the prevalence of diabetes among young adults increased rapidly due to lifestyle and socioeconomic changes (Wild et al., 2004). Taking immediate measures is of equal importance targeting university students to enhance awareness about diabetes from the public health approach. The previous studies have been revealed that 80% of T2D cases might be reduced by changing health behaviors like eating healthy diet and enhancing regular exercise and physical activity (Atlas, 2015; Galaviz, Narayan, Lobelo, & Weber, 2018).

However, this study found that only 42.5% of the respondents recognized that less physical activity and 43.6% of the respondents recognized that poor dietary pattern was risk factors of T2D onset. This situation is alarming because physical inactivity and unhealthy eating behaviors are common among youth in Pakistan (Imtiaz, ulHaq, Afaq, Khan, & Gillani, 2020). Evidence recommended that individuals who had high knowledge adopted healthier lifestyle were able to delay or prevent the onset of T2D (Okosun, Davis-Smith, & Seale, 2012). The study recommended that it is a need of the time to increase awareness and knowledge of diabetes risk factors and to develop models of health education and behavior change that are effective and relevant to university students (Mongiello et al., 2016).

6. Conclusion
The findings of the study showed shown that one fourth of the respondents had adequate knowledge of diabetes about its risk factors, sign and symptoms, and complication. Gender, marital status, blood glucose testing and family history of diabetes were associated with higher knowledge among the students. Lack of knowledge was common among all the respondents. These findings of the study demonstrated the urgent need of awareness programs and attention of medical professional and policy makers to take critical steps in decreasing the epidemic of diabetes in Pakistan.
