On a Newton filtration for functions on a curve singularity

W. Ebeling and S. M. Gusein-Zade *

Abstract

In a previous paper, there was defined a multi-index filtration on the ring of functions on a hypersurface singularity corresponding to its Newton diagram generalizing (for a curve singularity) the divisorial one. Its Poincaré series was computed for plane curve singularities non-degenerate with respect to their Newton diagrams. Here we use another technique to compute the Poincaré series for plane curve singularities without the assumption that they are non-degenerate with respect to their Newton diagrams. We show that the Poincaré series only depends on the Newton diagram and not on the defining equation.

Introduction

In [2, 3], there were defined two multi-index filtrations on the ring $\mathcal{O}_{\mathbb{C}^n,0}$ of germs of holomorphic functions in $n$ variables associated to a Newton diagram $\Gamma$ in $\mathbb{R}^n$ and to a germ of an analytic function $f : (\mathbb{C}^n,0) \rightarrow (\mathbb{C},0)$ with this Newton diagram. We assumed that the function $f$ was non-degenerate with respect to its Newton diagram $\Gamma$. These filtrations are essentially filtrations on the ring $\mathcal{O}_{V,0} = \mathcal{O}_{\mathbb{C}^n,0}/(f)$ of germs of functions on the hypersurface singularity $V = \{f = 0\}$. They correspond to the quasihomogeneous valuations on the ring $\mathcal{O}_{\mathbb{C}^n,0}$ defined by the facets of the diagram $\Gamma$. These facets correspond to some components of the exceptional divisor of a toric resolution of the germ $f$ constructed from the diagram $\Gamma$. Such a component defines the corresponding divisorial valuation on the ring $\mathcal{O}_{\mathbb{C}^n,0}$. For $n \geq 3$ (and for a $\Gamma$-non-degenerate $f$) these valuations induce divisorial valuations on the ring $\mathcal{O}_{V,0}$ and define

the corresponding multi-index filtration on it. The filtration defined in [2] was regarded as a certain “simplification” of the divisorial one. This appeared not to be the case. For example, a general formula for the Poincaré series of this filtration is not known even for the number of variables \( n = 2 \). For Newton diagrams of special type, A. Lemahieu identified this filtration with a so called embedded filtration on \( \mathcal{O}_{V,0} \) [7]. In [7], a formula for the Poincaré series of the embedded filtration for a hypersurface singularity was given. H. Hamm studied the embedded filtration and the corresponding Poincaré series for complete intersection singularities [9].

In [3], there was given an “algebraic” definition of the divisorial valuation corresponding to a Newton diagram (for \( n \geq 3 \)) somewhat similar to the definition in [2]. Roughly speaking, the difference consists in using the ring \( \mathcal{O}_{\mathbb{C}^n,0}[x_1^{-1}, \ldots, x_n^{-1}] \) instead of \( \mathcal{O}_{\mathbb{C}^n,0} \). For \( n = 2 \), this definition does not give, in general, a valuation, but an order function (see the definition below). For a \( \Gamma \)-non-degenerate \( f \in \mathcal{O}_{\mathbb{C}^2,0} \), this order function was described as a “generalized divisorial valuation” defined by the divisorial valuations corresponding to all the points of intersection of the resolution (normalization) \( \tilde{V} \) of the curve \( V \) with the corresponding component of the exceptional divisor. This permitted to apply the technique elaborated in [1] and to compute the corresponding Poincaré series. (This technique has no analogue which could be applied to degenerate \( f \), or to the case \( n > 2 \), or to the filtration defined in [2].) In this case the Poincaré series depends only on the Newton diagram \( \Gamma \) and does not depend on the function \( f \) with \( \Gamma_f = \Gamma \).

The definitions in [2] and [3] make also sense for functions \( f \) degenerate with respect to their Newton diagrams. Here we compute the Poincaré series of the filtration introduced in [3] for \( n = 2 \) directly from the definition without the assumption that \( f \) is non-degenerate with respect to the Newton diagram. We show that the answer is the same as in [3, Corollary 1] for non-degenerate \( f \). Thus, for \( n = 2 \), the Poincaré series of this filtration depends only on the Newton diagram \( \Gamma \). One can speculate that the same holds for \( n \geq 3 \) and for the Poincaré series of the filtration defined in [2].

We hope that some elements of the technique used here can be applied to the case \( n \geq 3 \) and/or to the filtration defined in [2] as well.

One motivation to study (multi-variable) Poincaré series of filtrations comes from the fact that they are sometimes related or even coincide with appropriate monodromy zeta functions or with Alexander polynomials (see e.g. [1]). We show that the obtained formula for the Poincaré series has a relation to the (multi-variable) Alexander polynomial of a collection of functions.
1 Filtrations associated to Newton diagrams

Let \((V, 0)\) be a germ of a complex analytic variety and let \(O_{V, 0}\) be the ring of germs of holomorphic functions on \((V, 0)\). A map \(v : O_{V, 0} \to \mathbb{Z}_{\geq 0} \cup \{+\infty\}\) is an order function on \(O_{V, 0}\) if \(v(\lambda g) = v(g)\) for a non-zero \(\lambda \in \mathbb{C}\) and \(v(g_1 + g_2) \geq \min\{v(g_1), v(g_2)\}\). (If, moreover, \(v(g_1 g_2) = v(g_1) + v(g_2)\), the map \(v\) is a valuation on \(O_{V, 0}\).) A collection \(\{v_1, v_2, \ldots, v_r\}\) of order functions on \(O_{V, 0}\) defines a multi-index filtration on \(O_{V, 0}\):

\[
J(v) := \{g \in O_{V, 0} : v(g) \geq v\}
\]

for \(v = (v_1, \ldots, v_r) \in \mathbb{Z}_{\geq 0}^r\), \(v(g) = (v_1(g), \ldots, v_r(g))\), \(v' = (v_1', \ldots, v_r') \geq v'' = (v_1'', \ldots, v_r'')\) iff \(v_i' \geq v_i''\) for all \(i = 1, \ldots, r\). (It is convenient to assume that the \(\Pi\) defines the subspaces \(J(v) \subset O_{V, 0}\) for all \(v \in \mathbb{Z}^r\).) The Poincaré series \(P\) can be defined as

\[
P_{\{v_i\}}(t) := \left(\frac{\sum_{v \in \mathbb{Z}^r} \dim(J(v))J(v + 1)2^v}{(t_1 t_2 \cdots t_r - 1)}\right) \prod_{t = 1}^{r-1} (t_i - 1)
\]

where \(1 = (1, \ldots, 1) \in \mathbb{Z}^r\), \(t^v = t_1^{v_1} \cdots t_r^{v_r}\) (see e.g. \([1]\); it is defined when the dimensions of all the factor spaces \(J(v) / J(v + 1)\) are finite). In \([1]\) it was explained that the Poincaré series \(P\) is equal to the integral with respect to the Euler characteristic

\[
P_{\{v_i\}}(t) = \int_{PO_{V, 0}} t^v d\chi
\]

over the projectivization \(\mathbb{P}O_{V, 0}\) of the space \(O_{V, 0}\). (In the integral \(t_i^{+\infty}\) has to be assumed to be equal to zero.)

Let \(f \in O_{C^n, 0}\) be a function germ with the Newton diagram \(\Gamma = \Gamma f \subset \mathbb{R}^n\), \(V := \{f = 0\}\). Let \(\gamma_i, i = 1, \ldots, r\), be (all) the facets of the diagram \(\Gamma\) and let \(\ell_i(\bar{k}) = c_i\) be the reduced equation of the hyperplane containing the facet \(\gamma_i\). One has \(\ell_i(\bar{k}) = \sum_{j=1}^n \ell_{ij} k_j (\bar{k} = (k_1, \ldots, k_n))\), where \(\ell_{ij}\) are positive integers, \(\gcd(\ell_{i1}, \ldots, \ell_{in}) = 1\).

For \(g \in O_{C^n, 0}[x_1^{-1}, \ldots, x_n^{-1}]\), \(g = \sum_{\bar{k} \in \mathbb{Z}^n} a_{\bar{k}} \bar{x}^{\bar{k}} (\bar{x} = (x_1, \ldots, x_n))\), let

\[
u_i(g) := \min_{k: a_{\bar{k}} \neq 0} \ell_i(\bar{k}).
\]

One can see that \(\nu_i\) is a valuation on \(O_{C^n, 0} \subset O_{C^n, 0}[x_1^{-1}, \ldots, x_n^{-1}]\). For a Newton diagram \(\Lambda\) in \(\mathbb{R}^n\), let

\[
u_i(\Lambda) := \min_{\bar{k} \in \Lambda} \ell_i(\bar{k}).
\]
(It is also equal to $u_i(g)$ for any germ $g$ with the Newton diagram $\Lambda$.) Let
\[ g_{\gamma_i}(\bar{x}) := \sum_{k \in E_i, (k) = u_i(g)} a_k \bar{x}^k. \]

The following two collections of order functions on $O_{\mathbb{C}^n,0}$ corresponding to the pair $(\Gamma, f)$ were defined in [2] and [3] respectively:

\[ v'_i(g) := \sup_{h \in O_{\mathbb{C}^n,0}} u_i(g + hf), \quad (4) \]

\[ v''_i(g) := \sup_{h \in O_{\mathbb{C}^n,0}[x_1^{-1}, \ldots, x_n^{-1}]} u_i(g + hf). \quad (5) \]

($v'_i$ and $v''_i$ are, in general, not valuations, at least when $n = 2$ or when $f$ is degenerate with respect to its Newton diagram $\Gamma$. They can be considered as order functions on the ring $O_{V,0} = O_{\mathbb{C}^n,0}/(f)$ as well. (These order functions and moreover the corresponding Poincaré series are, in general, different.)

Assume that the function $f$ is non-degenerate with respect to its Newton diagram $\Gamma$ and let $p : (X, D) \to (\mathbb{C}^n, 0)$ be a toric resolution of $f$ corresponding to the Newton diagram $\Gamma$. The facets $\gamma_1, \ldots, \gamma_r$ of $\Gamma$ correspond to some components (say, $E_1, \ldots, E_r$) of the exceptional divisor $D$. Let $\tilde{V}$ be the strict transform of the hypersurface singularity $V$ (it is a smooth complex manifold) and let $E_i := \tilde{V} \cap E_i$, $i = 1, \ldots, r$.

For $n \geq 3$, the set $E_i$ is an irreducible component of the exceptional divisor $D = D \cap \tilde{V}$ of the resolution $p : (\tilde{V}, D) \to (V, 0)$. The divisorial valuation $v_{E_i}$ on $O_{V,0}$ defined by this component coincides with $v''_i$: see [3]. For $n = 2$, the set $E_i$ is, in general, reducible (if the integer length $s_i$ of the facet (edge) $\gamma_i$ is greater than 1). Let $E_i = \bigcup_{j=1}^{s_i} E_i^{(j)}$ be the decomposition into the irreducible components ($E_i^{(j)}$ are points on the curve $\tilde{V}$). One can show that in this case $v''_i(g) = \min_j v_{E_i^{(j)}}(g)$, where $v_{E_i^{(j)}}$ are the corresponding divisorial valuations on $O_{V,0}$. This order function $v''_i$ can be regarded as a generalized divisorial valuation.

2 The Poincaré series

Let $\Gamma$ be a Newton diagram in $\mathbb{R}^2$ with the facets (edges) $\gamma_1, \ldots, \gamma_r$ and let $f$ be a function germ $\mathbb{C}^2, 0) \to (\mathbb{C}, 0)$ with the Newton diagram $\Gamma$. One can see that $f = x^a y^b \prod_{i=1}^r f_i$, where $f_i$ is such that $f_{\gamma_i} = \lambda_i \bar{x}^{\bar{k}_i} (f_i)_{\gamma_i}$ for certain $\lambda_i \in \mathbb{C}^*$ and $\bar{k}_i \in \mathbb{Z}^2_{\geq 0}$. The Newton diagram $\Gamma_i$ of the germ $f_i$ consists of one segment congruent (by a shift; in particular, parallel) to the facet $\gamma_i$ with the vertices on the coordinate lines in $\mathbb{R}^2$. 

4
Let $M_i = u_i(\Gamma_i)$, i.e. $M_i = (M_{i1}, \ldots, M_{ir})$, where $M_{ij} = u_{ij}(\Gamma_i)$. (One can see that $M_i = s_i M_i$ in the notations of [3].)

**Theorem 1** One has

$$P_{\{v''_i\}}(t) = \frac{\prod_{i=1}^r (1 - t^{M_i})}{(1 - t^{(s_i)}) (1 - t^{(u_i)})}. \quad (6)$$

**Corollary 1** For the number of variables $n = 2$ the Poincaré series $P_{\{v''_i\}}(t)$ depends only on the Newton diagram $\Gamma$ and does not depend on $f$ with $\Gamma_f = \Gamma$.

For the proof of Theorem 1 we need some auxiliary statements. We first introduce some notation.

For a Newton diagram $\Lambda$ in $\mathbb{R}^2$, let $\Sigma_\Lambda$ be the corresponding Newton polygon: $\Sigma_\Lambda = \bigcup \{ \vec{q} + \mathbb{R}^2_{\geq 0} \}$. Let $O^\Lambda$ be the set of functions $g \in O_{C^2,0}$ with the Newton diagram $\Gamma_g = \Lambda$. For $\nu \in \mathbb{Z}_{\geq 0}$, let $O^\Lambda_{\nu} = \{ g \in O^\Lambda : \nu''(g) = \nu \}$. The set $O^\Lambda_{\mu} \setminus \{0\}$ is the disjoint union of the sets $O^\Lambda$ over all diagrams $\Lambda$. According to [3] one has

$$P_{\{v''_i\}}(t) = \sum_{\Lambda} \int_{P^\Lambda} t^{\nu''(g)} d\chi. \quad (7)$$

For $g \in O^\Lambda$, one has $u''_i(g) \geq u_i(\Lambda)$.

We shall first show that the integrals in (7) can be restricted only to functions $g \in P^\Lambda$ with $\nu''(g) = \nu(\Lambda)$.

**Proposition 1** For a Newton diagram $\Lambda$ in $\mathbb{R}^2$, let $\nu \in \mathbb{Z}_{\geq 0}$ be such that $\nu > \nu(\Lambda)$, i.e. $\nu_i \geq u_i(\Lambda)$ for all $i = 1, \ldots, r$ and $\nu_i > u_i(\Lambda)$ for some $i$. Then the set $P^\Lambda_{\nu}$ has Euler characteristic equal to zero.

**Remark.** The direct analogue of this proposition does not hold for the filtration defined by the order functions $\{v'_i\}$. As an example one can take $f(x, y) = y^5 + xy^2 + x^2y + x^5$ with the Newton diagram $\Gamma$ with the set of vertices $\{(0, 5), (1, 2), (2, 1), (5, 0)\}$. One has $\ell_1(\bar{k}) = 3k_x + k_y$, $\ell_2(\bar{k}) = k_x + k_y$, $\ell_3(\bar{k}) = k_x + 3k_y$. Let $\Lambda$ be the Newton diagram with the set of vertices $\{(0, 5), (1, 2)\}$. One has $\nu(\Lambda) = (5, 3, 7)$. Let us take $\nu = (7, 3, 7)$. One can see that for the order functions $\{v'_i\}$ the set $O^\Lambda_{\nu}$ consists of the germs $g(x, y) = \sum a_{ij} x^iy^j$ from $O^\Lambda$ with $a_{05} = a_{12} \neq 0$ and $a_{06} = a_{13} = 0$. This gives $\chi(P^\Lambda_{\nu}) = 1$. For the order functions $\{v''_i\}$ the set $O^\Lambda_{\nu}$ consists of the germs with $a_{05} = a_{12} \neq 0$, $a_{06} = a_{13} = 0$ and $a_{07} + a_{14} + a_{21} \neq 0$. This gives $\chi(P^\Lambda_{\nu}) = 0$ in accordance with Proposition 1.

For the proof of Proposition 1 we need two lemmas.
Let $O^\Lambda$ be non-empty. For $g \in O^\Lambda$ with $\nu''(g) = \nu$ and for $i = 1, \ldots, r$, one can find $h_i \in O_{\mathbb{C}[x^{-1}, y^{-1}]}$ such that the Newton diagram of $g + h_i f$ lies in the (closed) half-plane $H_i = \{ k : \ell_i(k) \geq v_i \}$, but there are no $h$ for which the Newton diagram of $g + h f$ lies in the open half-plane $\{ k : \ell_i(k) > v_i \}$. Let $\Lambda^*$ be the union of the compact edges of the (infinite) polygon $\Sigma^*_\Lambda = \bigcap_{i=1}^r H_i \cap \Sigma^\Lambda$, where $\Sigma^\Lambda$ is the Newton polygon corresponding to $\Lambda$. ($\Lambda^*$ is not, in general, a Newton diagram since it may have non-integral vertices. Nevertheless we shall use the name “diagram” for it.)

Lemma 1 In the situation described above, there exists an edge $i$ ($1 \leq i \leq r$) such that $\Lambda^*$ has an edge $\delta_i$ parallel to $\gamma_i$ and (strictly) longer than $\gamma_i$.

Proof. We shall prove that there exists an edge of the diagram $\Lambda^*$ which is (strictly) longer than the edge of $\Lambda$ parallel to it. This implies that this edge is parallel to a certain edge $\gamma_i$ of the diagram $\Gamma$ and is longer than it. Since we assumed $O^\Lambda$ being non-empty, all edges of $\Lambda^*$ are parallel to edges of $\Lambda$. Let $a_0 < a_1 < \ldots < a_\sigma$ be the $k_x$-coordinates of all the vertices of $\Lambda$. Let $b_0 \leq b_1 \leq \ldots \leq b_\sigma$ be the $k_x$-coordinates of the corresponding vertices of $\Lambda^*$, i.e. $[b_{i-1}, b_i]$ is the projection of the segment of $\Lambda^*$ parallel to the segment of $\Lambda$ projected to $[a_{i-1}, a_i]$ ($b_{i-1}$ and $b_i$ may coincide). One can see that $a_0 = b_0$ and $a_\sigma \leq b_\sigma$. Then either $b_i = a_i$ for all $i = 0, 1, \ldots, \sigma$ or $[a_{i-1}, a_i] \not\subset [b_{i-1}, b_i]$ for some $i \in \{0, 1, \ldots, \sigma\}$. But the first case cannot happen since $\Lambda^* \neq \Lambda$. □

We shall also use the following generalized version of the division with remainder for Laurent polynomials.

Lemma 2 Let $p(z)$ and $q(z)$ be Laurent polynomials in $z$. Assume that $\text{supp} q$ has length $s$, i.e. $q(z) = \sum_{i=0}^s b_i z^{d+i}$ with $b_0 \neq 0$, $b_s \neq 0$, and let $d'$ be an integer. Then the polynomial $p(z)$ has a unique representation of the form $p(z) = q(z) a(z) + r(z)$ with $r(z) = \sum_{i=0}^{s-1} c_i z^{d'+i}$.

Proof of Proposition 7 Let $i$ be as in Lemma 1. Let the integer length of $\gamma_i$ be equal to $s_i$. Then the segment $\delta_i$ contains at least $s_i$ integer points. Let $Q_1, \ldots, Q_{s_i}$ be $s_i$ consecutive integer points on the segment $\delta_i$. Let $g \in O^\Lambda$ be such that $\nu''(g) = \nu$ ($> \nu(\Lambda)$) and let $\bar{g} = g + h f$ be a Laurent polynomial such that $\text{supp} \bar{g} \subset H_i = \{ \ell_i(k) \geq v_i \}$. Lemma 2 implies that $\bar{g}_{\gamma_i} (x, y) = f_{\gamma_i} (x, y) p_i (x, y) + r_i (x, y)$ where $\text{supp} r \subset \{ Q_1, \ldots, Q_{s_i} \}$ and $r_i \neq 0$ (otherwise $v_i (g) > v_i = u_i (\Lambda^*)$). (Let us recall that $\text{supp} f_{\gamma_i}$ consists of $s_i + 1$ consecutive points on the line containing $\gamma_i$.) Moreover the polynomial $r_i$ depends only on $g$ and does not depend on the choice of $\bar{g}$ (i.e. on the choice of $h$). 

6
One can see that all functions $g'$ of the form $g + (\lambda - 1)r_i$ with $\lambda \neq 0$ lie in $\mathcal{O}^\Lambda$ and satisfy the condition $v''(g') = v''(g)$. Thus the set $\mathbb{P}\mathcal{O}^\Lambda_{\mathbb{A}(\Lambda)}$ is fibred by $\mathbb{C}^*$-families and therefore its Euler characteristic is equal to zero.

Proposition 2 implies that

$$P_{\{v''\}}(t) = \sum_\Lambda \int_{\mathbb{P}\mathcal{O}^\Lambda_{\mathbb{A}(\Lambda)}} t^{v''}(g) d\chi.$$ (8)

**Proposition 2** Suppose that a Newton diagram $\Lambda$ contains an edge $\delta$ not congruent to any edge of $\Gamma$, i.e. either not parallel to all the edges $\gamma_i$, or parallel to one of them, but of another length. Then $\chi(\mathbb{P}\mathcal{O}^\Lambda_{\mathbb{A}(\Lambda)}) = 0$.

**Proof.** Assume first that the edge $\delta$ is either not parallel to all the edges $\gamma_i$, or it is parallel to $\gamma_i$, but is shorter than $\gamma_i$. Let $\bar{q} = (q_x, q_y)$ and $\bar{q'} = (q'_x, q'_y)$, $q_x > q'_x$, be the vertices of the edge $\delta$ and let $\Lambda'$ be the set of points $k$ in $\Lambda$ with $k_x \geq q_x$. A function germ $g \in \mathcal{O}^\Lambda_{\mathbb{A}(\Lambda)}$ can be represented as $g_1 + g_2$, where $\text{supp } g_1 \subset \Lambda'$, $\text{supp } g_2 \subset \Sigma \setminus \Lambda'$. (Note that $g_1 \neq 0$ and $g_2 \neq 0$.) One can see that all the functions of the form $g_1 + \lambda g_2$ with $\lambda \neq 0$ lie in $\mathcal{O}^\Lambda_{\mathbb{A}(\Lambda)}$. Thus the set $\mathbb{P}\mathcal{O}^\Lambda_{\mathbb{A}(\Lambda)}$ is fibred by $\mathbb{C}^*$-families and therefore its Euler characteristic is equal to zero.

Now assume that the edge $\delta$ of the diagram $\Lambda$ is parallel to $\gamma_i$ and is longer than it. Let $\bar{q} = (q_x, q_y)$ and $\bar{q'} = (q'_x, q'_y)$, $q_x > q'_x$, (respectively $\bar{q}_0 = (q_{0x}, q_{0y})$, $q_{0x} > q'_{0x}$) be the vertices of the edge $\delta$ (respectively of the edge $\gamma_i$) and let $\Lambda'$ be defined as above: $\Lambda' = \{k \in \Lambda : k_x \geq q_x\}$. Let $g(\bar{x}) = \sum a_kx^k \in \mathcal{O}^\Lambda_{\mathbb{A}(\Lambda)}$, $f(\bar{x}) = \sum c_kx^k$ $(\bar{x} = (x, y))$ and let

$$g_1(\bar{x}) = g_{\Lambda'}(\bar{x}) - a_{\bar{q}}\bar{x} + (a_{\bar{q}}/c_{\bar{q}_0})f_{\gamma_i}(\bar{x}) \cdot \bar{x}^2 - \bar{q}_0,$$

where $g_{\Lambda'}(\bar{x}) = \sum_{k \in \Lambda'} a_kx^k$, $g_2 = g - g_1$. One has $\text{supp } g_1 \subset \Lambda' \cup (\bar{q}, \bar{q'})$, $\text{supp } g_2 \subset \Sigma \setminus \Lambda'$, $\mathbb{F}_{\gamma_i}(g_2)_{\gamma_i}$ (in $\mathcal{O}_{C^2,0}[x^{-1}, x^{-1}]$), where $(\bar{q}, \bar{q'})$ denotes the open line segment connecting the two points. All the functions of the form $g_1 + \lambda g_2$ with $\lambda \neq 0$ lie in $\mathcal{O}^\Lambda_{\mathbb{A}(\Lambda)}$. Thus the set $\mathbb{P}\mathcal{O}^\Lambda_{\mathbb{A}(\Lambda)}$ is again fibred by $\mathbb{C}^*$-families and therefore its Euler characteristic is equal to zero.

**Proposition 3** Let the Newton diagram $\Lambda$ consist (only) of segments congruent to $\gamma_i$ for $i \in I \subset \{1, \ldots, r\}$. Then $\chi(\mathbb{P}\mathcal{O}^\Lambda_{\mathbb{A}(\Lambda)}) = (-1)^{\#I}$.

**Proof.** For $I = \emptyset$, the statement is obvious. Let $I \neq \emptyset$. Let $\mathbb{P}\mathcal{O}^\Lambda_i$ be the set of functions $g \in \mathbb{P}\mathcal{O}^\Lambda_{\mathbb{A}(\Lambda)}$ with $f_{\gamma_i}g_{\gamma_i}$ (in $\mathcal{O}_{C^2,0}[x^{-1}, x^{-1}]$). One has

$$\mathbb{P}\mathcal{O}^\Lambda_{\mathbb{A}(\Lambda)} = \mathbb{P}\mathcal{O}^\Lambda \setminus \bigcup_{i \in I} \mathbb{P}\mathcal{O}^\Lambda_i.$$
Therefore
\[
\chi(\mathbb{P}O^\Lambda_{\Delta(A)}) = \chi(\mathbb{P}O^\Lambda_A) + \sum_{I' \subseteq I, I' \neq \emptyset} (-1)^{\#I'} \chi \left( \bigcap_{i \in I'} \mathbb{P}O_i^\Lambda \right). \tag{9}
\]

Let \( \bar{q}_i, i = 0, 1, \ldots, \#I \), be the vertices of the diagram \( \Lambda \). The set \( \mathbb{P}O^\Lambda_A \) consists of functions \( g(\bar{x}) = \sum a_i \bar{x}^k \) with \( a_i \neq 0 \) for \( i = 0, 1, \ldots, \#I \) and \( a_k = 0 \) for \( k \not\in \Sigma^\Lambda \). Its Euler characteristic is equal to zero. Assume that \( I' \subseteq I, I' \neq \emptyset \). Let \([\bar{q}, \bar{q}']\) be an edge of \( \Lambda \) congruent to \( \gamma_i, i \in I \setminus I' (\bar{q} = (q_x, q_y)), \bar{q}' = (q'_x, q'_y), q_x > q'_x \). Let \( \Lambda' = \{ k \in \Lambda : k_x \geq q_x \} \). For \( g \in \bigcap_{i \in I'} \mathbb{P}O_i^\Lambda \), let \( g_1(\bar{x}) = g_{\Lambda'}(\bar{x}), g_2 = g - g_1 \). All the functions of the form \( g_1 + \lambda g_2 \) with \( \lambda \neq 0 \) belong to \( \bigcap_{i \in I'} \mathbb{P}O_i^\Lambda \). Thus \( \bigcap_{i \in I'} \mathbb{P}O_i^\Lambda \) is fibred by \( \mathbb{C}^* \)-families and therefore \( \chi(\bigcap_{i \in I'} \mathbb{P}O_i^\Lambda) = 0 \).

Let \( f_i(\bar{x}) := \prod_{i \in I} f_i(\bar{x}) \). The intersection \( \bigcap_{i \in I} \mathbb{P}O_i^\Lambda \) (the Euler characteristic of which corresponds to \( I' = I \) in (9)) consists of the functions \( g \in \mathbb{P}O_{\mathbb{C}^2,0}^\Lambda \) such that \( g_{\Lambda}(\bar{x}) = \lambda \bar{x}^k(f_I)_{\Gamma_I} \), where \( \Gamma_I \) is the Newton diagram of \( f_I \), \( \lambda \neq 0 \) and \( \bar{x}^k \) is a certain monomial. Therefore
\[
\chi \left( \bigcap_{i \in I} \mathbb{P}O_i^\Lambda \right) = 1.
\]

**Proof of Theorem** Propositions 1 and 2 imply that
\[
P_{\{v''\}}(\ell) = \sum_{\Lambda} \int_{\mathbb{P}O_{\Delta(A)}^\Lambda} p^{v''}(g) d\chi
\]
where the sum runs over all diagrams \( \Lambda \) consisting only of edges congruent to some of the edges \( \gamma_i \) of the diagram \( \Lambda \). Let the edges of \( \Lambda \) be congruent to the edges \( \gamma_i \) with \( i \in I = I(\Lambda) \). Proposition 3 implies that the summand in (10) corresponding to such a diagram \( \Lambda \) is equal to \( (-1)^{\#I} \ell^{v''(\Lambda)} \). All the diagrams of this sort are obtained from the diagrams \( \Gamma_I = \Gamma_{f_I} \) by shifts by non-negative integral vectors \( \tilde{k} \), i.e. \( \Lambda = \tilde{k} + \Gamma_I \). One has \( u(\Lambda) = \ell(\tilde{k}) + \sum_{i \in I} M_i \). Therefore
\[
P_{\{v''\}}(\ell) = \sum_{k \in \mathbb{Z}^{\geq 0}} \sum_{I \subseteq \{1, \ldots, r\}} (-1)^{\#I} \ell^{\ell(\tilde{k}) + \sum_{i \in I} M_i}
\]
\[
= \left( \sum_{k \in \mathbb{Z}^{\geq 0}} \ell^{\ell(\tilde{k})} \right) \cdot \left( \sum_{I \subseteq \{1, \ldots, r\}} (-1)^{\#I} \sum_{i \in I} M_i \right)
\]
\[
= \prod_{i=1}^{r} (1 - \ell^{M_i})
\]
\[
\left( 1 - \ell^{s(\bar{x})} \right) (1 - \ell^{u(y)})
\].

\[\square\]
3 Relation with an Alexander polynomial

One can see that the equation (6) gives the Poincaré series $P_{\{v''\}}(t)$ as a finite product/ratio of “cyclotomic” binomials of the form $(1 - t^M)$ with $M \in \mathbb{Z}_{>0}$. This looks similar to the usual A’Campo type expressions for monodromy zeta functions or for Alexander polynomials of algebraic links [4]. Here we shall describe a relation between the Poincaré series (6) and a certain Alexander polynomial.

A notion of the multi-variable Alexander polynomial for a finite collection of germs of functions on $(\mathbb{C}^n, 0)$ was defined in [8]: see Proposition 2.6.2 therein. (In [8] it is called the (multi-variable) zeta function.) In a somewhat more precise form this definition can be found in [5]. (The definition in [5] gives the one for a collection of functions if one considers the corresponding principal ideals.)

As above, let $\Gamma$ be a Newton diagram in $\mathbb{R}^2$ with the edges $\gamma_1, \ldots, \gamma_r$ of integer lengths $s_1, \ldots, s_r$ and let $p : (X, D) \to (\mathbb{C}^2, 0)$ be a toric modification of $(\mathbb{C}^2, 0)$ corresponding to the diagram $\Gamma$. For $i = 1, \ldots, r$, let $\tilde{C}_i$ be a germ of a smooth curve on $X$ transversal to the component $E_i$ of the exceptional divisor $D$. Let $C_i = p(\tilde{C}_i)$ be the image of $\tilde{C}_i$ in $(\mathbb{C}^2, 0)$ and let $L_i = C_i \cap S^3_\varepsilon$ be the corresponding knot in the 3 sphere $S^3_\varepsilon = S^3_\varepsilon(0)$ for $\varepsilon > 0$ small enough. The curve $C_i$ can be defined by an equation $g_i = 0$ where $g_i$ is a function germ $(\mathbb{C}^2, 0) \to (\mathbb{C}, 0)$ with the Newton diagram consisting of one segment parallel to $\gamma_i$, with the (integer) length 1 and with the vertices on the coordinate lines.

Let $\Delta_g(t)$ and $\Delta_{g^s}(t)$ be the Alexander polynomials of the collections of functions $g = (g_1, \ldots, g_r)$ and $g^s = (g_1^{s_1}, \ldots, g_r^{s_r})$ respectively. The polynomial $\Delta_g(t)$ is the classical Alexander polynomial $\Delta^L(t)$ of the link $L = \bigcup L_i$ (see e.g. [4]). A one-variable analogue of $\Delta_{g^s}(t)$ is considered in [4, I.5] as the Alexander polynomial of the multilink $L(\bar{g}) = \bigcup L_i$. One has

$$\Delta_g(t) = \prod_{i=1}^{r} \frac{1 - t^{s_i}}{(1 - t^{s_i})(1 - t^{s_i^c})},$$

$$\Delta_{g^s}(t) = \prod_{i=1}^{r} \frac{1 - t^{s_i m_i}}{(1 - t^{s_i(x)})(1 - t^{s_i(y)})},$$

where $s m_i = (s_1 m_{i1}, s_2 m_{i2}, \ldots, s_r m_{ir})$. The main result of [4] says that $\Delta_g(t) = \Delta^L(t)$ coincides with the Poincaré series of the filtration corresponding to the Newton diagram of the function $\prod_{i=1}^{r} g_i$.

Let the reduced Poincaré series of the filtration defined by $\{v''\}$ be

$$\tilde{P}_{\{v''\}}(t) := P_{\{v''\}}(t)/P_{\{u_i\}}(t), \quad P_{\{u_i\}}(t) = \frac{1}{(1 - t^{s_i}(x))(1 - t^{s_i}(y))}.$$
being the Poincaré series of the filtration defined by the quasihomogeneous valuations $\{u_i\}$ on $\mathcal{O}_{\mathbb{C}^2,0}$. One has

$$\tilde{P}_{\{u_i\}}(t) = \prod_{i=1}^{r}(1 - t^{s_i u_i}). \quad (11)$$

Let

$$\tilde{\Delta}_{\mathfrak{g}}(t) := \Delta_{\mathfrak{g}}(t)/\Delta_{\mathfrak{g}_x}(t) \cdot \Delta_{\mathfrak{g}_y}(t)$$

where $\Delta_{\mathfrak{g}}(t)$ and $\Delta_{\mathfrak{g}_x}(t)$ are the Alexander polynomials of the sets of functions $\mathfrak{g} = \{g_1^{s_1}, \ldots, g_r^{s_r}\}$ restricted to the coordinate axes $\mathbb{C}_x$ and $\mathbb{C}_y$ respectively. One can regard $\tilde{\Delta}_{\mathfrak{g}}(t)$ as the Alexander polynomial of the set of functions $\mathfrak{g}$ restricted to the complex torus $(\mathbb{C}^*)^2 \subset \mathbb{C}^2$. One has

$$\tilde{\Delta}_{\mathfrak{g}}(t) = \prod_{i=1}^{r}(1 - t^{s_i u_i}). \quad (12)$$

One can see that a relation between (11) and (12) can be described in the following way. Consider products of $r$ ordered cyclotomic binomials in $r$ variables. Such a product

$$\prod_{i=1}^{r}(1 - t^{N_i}), \quad N_i = (N_{i1}, \ldots, N_{ir}),$$

can be described by the corresponding $r \times r$-matrix $N := (N_{ij})$. The transposition of the matrix induces an involution on the set of products of this sort. One can see that this involution maps the product (11) for the Poincaré series to the product (12) for the Alexander polynomial.
