On local polynomial estimation of hazard rates and their derivatives under left truncation and right censoring models

Abstract

Estimating hazard rate function is an important problem in survival analysis. There are some estimation approaches based on kernel smoothing. However, they suffer from the boundary effects or need high order kernels, which increases the mean squared error. We introduce local polynomial estimators of hazard rates and their derivatives for the left truncation and right censoring models. The estimators have favorable properties similar to those of local polynomial regression estimators. Asymptotic expressions for the mean squared errors (AMSE’s) are obtained. Consistency and joint asymptotic normality of the local polynomial estimators are established. A data-based local bandwidth selection rule is proposed.

Keywords: censoring, data-driven local bandwidth selection, hazard rate, local polynomial, truncation

Introduction

Consider a subject in survival studies. Only if its onset time, i.e. the time origin of its lifetime, passes the beginning of the study, the subject can enter into the study. For the entered individuals, each of them is then followed for a fixed time point. Such subjects are so-called left truncated and right censored. To be specific, let X be the lifetime with distribution function (df) G(x), and C the random censoring time with arbitrary df L(x), where X is independent of (T,C). Then the cumulative hazard function of F(x) is \( \Lambda(x) = \int_0^x \frac{dF(t)}{1-F(t)} \).

Under the left truncation and right censoring model, one observes \((Y,T,\delta)\) if \(Y \geq T\), where \( T = \min(X,C) \) and \( \delta = I(X \leq C) \) is an indicator of the censoring status of X which takes value one if \( X \leq C \) and zero otherwise. When \( Y < T \), nothing is observed (see for example, Gurler & Wang\(^4\)). Let the distribution of \( Y \) be \( W(y) \) and assume that \( \alpha = P(Y \leq Y) > 0 \). Then \( \tilde{W} = \int_0^\alpha \) where and throughout the paper for any df. \( E, \tilde{E} = 1 - E \) is the corresponding survival function.

The left truncation and right censoring model has been investigated by many authors. Interesting work along the field can be found in Gross & Lai\(^2\) and Gurler & Wang\(^3\) among others. Several authors have considered the estimation of hazard functions under the left truncation and right censoring model. For examples, Uzunogullari & Wang\(^7\) and Wu & Wells\(^8\).

In the present investigation, we study local polynomial (LP for short) estimators of hazard functions and their derivatives based on the i.i.d sample \( \{(Y_i,T_i,\delta_i)\}_{i=1}^n \) from \((Y,T,\delta)\). Under the left truncation and right censoring model, one observes only those i.i.d pairs \((Y_i,T_i,\delta_i)\) for which \( Y_i \geq T_i \). It is worth pointing out that our estimators inherit some favorable properties from local polynomial regression estimators, in particular, our estimators can reduce the bias according to the degree of the polynomial without increasing the variance and automatically correct the left boundary effect. The point wise asymptotic normality of our estimators enables one to find the asymptotically optimal variable bandwidth choice, and thereafter allows one to develop a data-driven optimal local bandwidth selector by using the ideas of Fan & Gijbels.\(^5\) We here present a simpler data-driven method for choosing the local bandwidth.

The outline of this paper is as follows. In Section 2, we introduce the LP estimators. In Section 3 we concentrate on the asymptotic properties of the proposed estimators, including point wise strong consistency and joint asymptotic normality. In Section 4, we propose the data-driven local bandwidth selection rule. Technical proofs are given in the Appendix.

Estimation

In order to introduce the LP estimators, we use the following notation from Gurler & Wang\(^9\):

(i) \( C(z) = P(T \leq z \leq Y \mid Y \geq T) = \alpha^{-1}P(T \leq z \leq C)\) \(\overline{\Lambda}(z) \) \(C(z) \),

(ii) \( C_{x}(z) = (n+1)^{-1}\sum_{j=1}^n I(T_j \leq z \leq Y_j) \), the modified empirical estimator of \( C(z) \).

(iii) \( F_{x}(s) = 1 - \pi_{y \leq s}(1 - [nC_{x}(Y_j)^{-1}]^{n-y}) \), the product-limit estimator of \( F(x) \) from Tsai, et al.\(^6\).

Let \( a_\ell = \inf \{ t : E(t) > 0 \} \) and \( b_\ell = \inf \{ t : E(t) = 1 \} \) denote the left and right endpoints of the support for any d.f. \( E(x) \) respectively. Then \( F(x) \) is identifiable if \( a_\ell \leq a_\beta \) and \( b_\ell \leq b_\beta \) (Woodroofe\(^6\) and Gurler & Wang\(^3\)).

Therefore, we assume this condition holds. As in Gurler & Wang,\(^1\) for estimating the density function \( f(x) \) of \( X \), we also assume \( a_\ell \leq a_\alpha \).

Following Gurler & Wang,\(^1\) we define \( W_{\ell}(y) = P(Y \leq y, \delta = 1)\) \(\overline{\Lambda}(y) \) \(W_{\ell}(y) \) and \( W_{\ell}(y) = n^{-1}\sum_{j=1}^n I(Y_j \leq y, \delta_j = 1) \). Then \( dW_{\ell}(y) = \alpha^{-1}P(T \leq Y \leq C) dF(y) \) and...
$\Lambda(x) = \int_0^x dW_r(y)/C(y)$.

By Gurler & Wang, the Nelson-Aalen type estimator of $\Lambda(x)$ is given by

$$\hat{\Lambda}_m(x) = \frac{1}{m} \sum_{i=1}^m \left( \frac{x - a}{b} \right) dF(x).$$

Gurler & Wang considered the following kernel estimator for the density function $f(x)$ of $X_i$, which is a convolution of the product of the kernel function $K(x)$ and the empirical estimator of $\Lambda(x)$ with an appropriate kernel function $K_x(u)$:

$$\hat{f}_n(x) = \frac{1}{b_n} \int K_n(x - u) dF(u),$$

where $K_n$ is a higher order kernel. The method can be also adapted to the case of estimating $\Lambda(x)$ and its derivatives if $\Lambda_n(x)$ instead of $F_n(x)$:

$$\hat{\Lambda}_n(x) = \frac{1}{b_n} \int K_n(x - u) d\Lambda_n(u).$$

The estimator is an extension to that of Müller & Wang where right censoring model is considered. However, for the estimation of derivatives or reduction of bias, the estimator needs higher order kernels, which can lead to a negative hazard rate estimator. The practical advantages of using higher order kernels can be quite small as the number of observations is small, which contrasts with the results for other hazard rate estimators. Taking the derivative with respect to $a$'s of the integral in (6), we obtain the LP estimator as the solution to the linear equations:

$$\sum_{j=1}^n \lambda_{ij} = \frac{1}{b_n} \int K_n(x - u) d\Lambda_n(u).$$

where $\lambda_{ij}$ is the Dirac function with the following property:

$$\int g(u) \lambda(u - x) du = g(x),$$

for any integral function $g(x)$. Then $\int g(u) \lambda(u) dt = \Lambda_n(x)$, which is why we call $\lambda_n$ the generalized empirical hazard rate. Replacing $\lambda_n$ in (4) by $\hat{\lambda}_n$, we obtain that

$$\hat{\lambda}_n = \frac{1}{b_n} \int K_n(x - u) d\Lambda_n(u).$$

Then $\hat{\lambda}_n(x)$ is the LP estimator of $\lambda_n(x)$. Jones considered a locally linear estimator and established its link with the generalized jackknife boundary correction for $p = 1$ by using the ideas of Lejeune & Sarda in local linear fitting to the empirical distribution $F_n$. Here we study the local polynomial estimation of hazard functions and their derivatives, $\lambda_n(x)$, under the left truncation and right censoring model. Obviously, our method can be used for the complete data case, which corresponds to "no truncation and no censoring".

Taking the derivative with respect to $a$'s of the integral in (6), we obtain the LP estimator as the solution to the linear equations:

$$\sum_{j=1}^n \lambda_{ij} = \frac{1}{b_n} \int K_n(x - u) d\Lambda_n(u).$$

(7)

It follows that the LP estimator at any point $x_0 \in (a_0, b_p)$ has the following closed form:

$$\hat{\lambda}_n(x_0) = S^{-1} \lambda_n(x_0),$$

(8)

where $S_n(x_0) = (S_{n1}(x_0), \ldots, S_{np}(x_0))^T$, and

$$S_{nj}(x_0) = \sum_{i=1}^n \lambda_{ij} K_n(x_0 - x_i) d\Lambda_n(x).$$

(9)

When $p = 0$ and $s_0 = 1$,

$$\hat{\lambda}_0 = \frac{1}{b_n} \int K_n(x - u) d\Lambda_n(u).$$

which is the same as the kernel estimator of $\lambda_0(x)$ in (3). However, this equivalence does not hold for boundary points.

We will show in next section that the LP estimator shares nice properties with the local polynomial regression estimator, in particular, the estimator will keep its convergence rate up to the left boundary point, i.e. the estimator automatically corrects the left boundary effect, which contrasts with the results for other hazard rate estimators.

### Asymptotic properties

In this section, we will establish the consistency and joint asymptotic normality of the local polynomial estimators. To this end, we introduce some regularity conditions. For a given point

On local polynomial estimation of hazard rates and their derivatives under left truncation and right censoring models

Theorem 3.3
Consider the left edge effect on the estimator. Assume that we estimate \( \lambda(x) \) at \( x_0 = b_h \) in the left boundary region for some positive constant \( d \in [0,1] \). Then similar to (8), \( \lambda(x_0) \) has the following closed form, for \( p = 0,1,2, \ldots \),

\[
\tilde{\lambda}_k(x_0) = \text{S}_{\lambda}(x_0),
\]

where \( \text{S}_{\lambda} \) defined as \( S \) but with \( s_j \) replaced by \( s_{j,d} = \int_{x_0}^{x-d} K(u)du \). Let \( v_{ij} = \int_a^{x-d} K(u)du \). Then the joint asymptotic normality (10) continues to hold with \( v_s \) and \( v^* \) replaced by \( e_{ij} \), \( \tilde{v}_s \) and \( \tilde{v}^* \), respectively, where \( e_{ij} = (s_{p+1,d}; \ldots; s_{2p+1,d})^T \) and \( \tilde{v}^* = (v_{ij}, d) \) is \((p+1) \times (p+1)\) matrices.

This property of our estimator in Theorem 3.3 is similar to that of local polynomial regression estimation, which is not shared by other kernel estimators of hazard rates (Hess et al.14) The LP estimators are automatically boundary adaptive in the sense of Fan & Gijbels.15 Note that the above property holds even for \( p = 0 \), which contrasts with the cases of local polynomial regression.

Remark 3.3
For a finite sample, one may encounter right boundary effects when estimating near \( T \). A good method for dealing with the problem is to use the following estimator similar to the estimator in (13):

\[
\tilde{\lambda}_k(x_0) = \text{S}_{\lambda}(x_0),
\]

where \( x = T - q b_h \) for \( q \in [0,1] \), and \( S_{\lambda} \) defined as \( S \) but with \( s_j \) replaced by \( s_{j,d} = \int_{x_0}^{x-d} K(u)du \).

Data-driven local bandwidth choice

The proposed estimators depend on the bandwidth \( b_h \). It is important to develop a local bandwidth choice for estimating hazard functions and their derivatives, especially when one would like to have a data-driven approach to bandwidth choice in practice. For hazard rate estimation, Patil16 considered least squares cross-validation bandwidth selection, and Gonzalez-Manteiga et al.17 studied smoothed bootstrap selection of the global bandwidth. Müller & Wang,18 Hess et al.14 and Jiang & Doksum19 studied the local bandwidth choice for estimating hazard rates under right censoring. Here we extend the data-driven local bandwidth choice of Jiang & Doksum19 to the left truncation and right censoring model.

From the proof of Theorem 3.2, we see that the exact bias of the estimator \( \hat{\lambda}_k(x_0) \) is

\[
B_k(b_h, x_0) = e_k^T (S^{-1} B_k(x_0) - \text{B}(x_0)),
\]

where \( B_k(x_0) = (B_{LW}(x_0), B_{op}(x_0))^T \) and \( \beta_k(x_0) = |K(t)dt| \tilde{\lambda}(x_0 + b_h t)dt \). The asymptotic variance of \( \hat{\lambda}_k(x_0) \) is

\[
V_k(b_h, x_0) = \frac{1}{n b_h^2} e_k^T (S^{-1} V_k(x_0)) e_k,
\]

where \( V_k = (v_{ij}) \) and \( v_{ij} = |K(t)dt| \tilde{\lambda}(x_0 + b_h t)dt \). Then we propose to estimate the AMSE of \( \hat{\lambda}_k(x_0) \) via
On local polynomial estimation of hazard rates and their derivatives under left truncation and right censored models

Algorithm for estimating \( \lambda(x) \):

**Step 1:** Pilot estimators of \( \lambda(x) \) : Choose a kernel, such as the Epanechnikov kernel, and an initial global bandwidth \( h_0 \). The choice of the initial bandwidth depends on the specific case. Assume the data are available on \([0, T]\), then a possible value for \( h_0 \) is \( T/(8n_0^2) \) as recommended by Muller & Wang,\(^1\) where \( n_0 \) is the number of uncensored observations. The pilot estimators \( \hat{\lambda}(x) \) of \( \lambda(x) \) are obtained by using \( h(x) = h_0 \) and our estimators (8), (13) and (14).

**Step 2:** Minimizing of \( AMSE_i(h_i, x) \) : Choose an equispaced grid of \( m \) points \( \tilde{x}_j, j = 1,\cdots,m \), between 0 and \( T \). For each of the grid points \( \tilde{x}_j \) compute \( AMSE_i(h_i, x) \) in (17) with \( k = 0 \) and obtain its minimizes \( \hat{b}(\tilde{x}_j) \) on the interval \([h_0/4, 4h_0]\), say. The minimization of \( AMSE(h_i, \tilde{x}_j) \) may be computed via Discretisation.

**Step 3:** Smoothing bandwidths: Choose another equispaced grid of \( m^2 \) points \( x_r, r = 1,\cdots,m^2 \), over the interval \([0, T]\) on which the final hazard estimator is desired. Running local linear smoother by employing global bandwidth \( h_0 = h_0 \) or \( 2h_0 \):

\[
b(x) = \frac{\sum_{j=1}^{m} \tilde{b}(\tilde{x}_j)}{\sum_{j=1}^{m} \tilde{w}_j},
\]

where \( \tilde{w}_j = K\left(\frac{\tilde{x}_j - x}{h_0}\right) \left[\sum_{j=1}^{m} K\left(\frac{\tilde{x}_j - x}{h_0}\right)\right]^{-1} \)

and

\[
M_{n,j} = \sum_{j=1}^{m} K\left(\tilde{x}_j - x\right) \frac{\tilde{b}(\tilde{x}_j)}{\sum_{j=1}^{m} \tilde{w}_j}, \quad \text{for } j = 1, 2.
\]

**Step 4:** Final hazard function estimators: Using (8), (13) and (14), obtain the estimators \( \hat{\lambda}(x) \) by employing the bandwidth \( b(x) \), for \( r = 1,\cdots,m^2 \).

The above algorithm can be repeated by using the estimators \( \hat{\lambda}(x) \) in Step 4 as pilot estimators in Step 1 and running Step 2 - Step 4 again. The pilot estimators of \( \hat{\lambda}(x) \) in Step 1 can also be obtained via maximum likelihood if one has a plausible parametric model in mind.\(^1\)

### Appendix proofs of theorems

**Proofs of theorems 3.1 and 3.2**

(i) Using (1) and (9), we obtain that

\[
S_{n,t}(x_0) = \int h_0 K\left(\frac{u - x_0}{b_0}\right) d\Lambda_u(u) + \int h_0 K\left(\frac{u - x_0}{b_0}\right) d\Lambda(u) + \int h_0 K\left(\frac{u - x_0}{b_0}\right) d\Lambda(u) - \int h_0 K\left(\frac{u - x_0}{b_0}\right) d\Lambda_u(u).
\]

(ii) Using (17) and (18), we get

\[
AMSE_i(b_i, x_0) = \hat{b}_i^2(b_i, x_0) + \hat{V}_i(b_i, x_0),
\]

where \( \hat{b}_i(b_i, x_0) \) and \( \hat{V}_i(b_i, x_0) \) are defined similarly to \( B_i(b_i, x_0) \) and \( V_i(b_i, x_0) \) but with \( \lambda(x) \) replaced by a pilot estimator and \( C(x) \) replaced by its empirical estimator \( C_i(x) \). We define

\[
\hat{b}_i(x_0) = \arg\min_{\hat{b}} AMSE_i(b, x_0).
\]

Then, for estimating \( \lambda(x) \) when \( p = 1 \), the following algorithm similar to Jiang and Dokuom\(^1\) can be used for estimating \( \lambda(x) \).

Citation: Jiang J., Chen L. Yuan Y. On local polynomial estimation of hazard rates and their derivatives under left truncation and right censoring models. Biom Biostat Int J. 2018;7(3):199-203. DOI: 10.15406/bbij.2018.07.00209
is the stochastic component of $S_n(x_0)$ and contributes to the variance of our estimator, and $e_n(x_0)$ is the negligible error of the approximation which satisfies

$$
\sup_{0<\epsilon<p} |e_n(x_0)| = O\left(\frac{\log n}{n}\right), \text{ a.s.}
$$

for $0 \leq \epsilon \leq p$ . Note that $E(\sigma_n(x_0)) = 0$ and

$$
\text{Cov}(\sigma_n(x_0), \sigma_m(x_0)) = \frac{1}{nb_n^2} \left\{ \frac{1}{b_n^2} E(\min(x_0 + b_nu, x_0 + b_nv)) \right\} dK_n(u) dK_m(v)
$$

for $0 \leq u \leq v$, which satisfies

$$
= \frac{1}{nb_n^2} \left\{ \frac{1}{b_n^2} \int_{(x_0 - b_n, x_0 + b_n)} \min(u, v) \right\} dK_n(u) dK_m(v)
$$

Let

$$
\sigma_n(x_0) = (\sigma_{n \theta}, \cdots, \sigma_{n \gamma})^T \quad \text{and} \quad e_n(x_0) = (e_{n \theta}, \cdots, e_{n \gamma})^T.
$$

Then by (22) and (24)

$$
\sqrt{nb_n} S^{-1} e_n(x_0) = \frac{1}{nb_n} \sqrt{S^{-1} e_n(x_0)} \sim N(0, \sigma_n(x_0)^{-1}).
$$

By the central limit theorem, we get

$$
\sqrt{nb_n} \sigma(x_0) \rightarrow N(0, \sigma(x_0)^{-1}).
$$

Combination of (19), (20) and (28) completes the proof of Theorem 3.2.

(ii) Note that $\sigma_{n}(x_0)$, for $\epsilon = 0, \cdots, p$, are i.i.d.'s sums. By the SLN, we know $\sigma_{n}(x_0) \rightarrow E(\sigma_{n}(x_0)) = 0$. Then $\sigma_{n}(x_0) \rightarrow 0$. This combined with (22) and (23) yields $\gamma_n(x_0) \rightarrow 0$. Therefore, by (19) and (20),

$$
B_n(\hat{a}(x_0)) - a(x_0) \rightarrow 0.
$$
