ABSTRACT

Objective: Iron disorder and abnormal expression of hepcidin play important roles in many diseases, but it is still unclear in type 2 diabetes mellitus (T2DM). Current study aimed to assess iron, ferritin and hepcidin levels in plasma of with or without T2DM and evaluate increased body iron stores as risk factor for developing T2DM.

Methods: Plasma samples were collected from 88 participants, who were categorized into 2 groups based on the presence or absence of T2DM. Demographics and general health parameters were recorded. Chemiluminescence microparticle immunosassay and enzyme-linked immunosorbent assay were used to detect iron, ferritin and hepcidin concentrations. The geometric mean±SD of the plasma level of hepcidin, ferritin, iron and insulin among T2DM comparing with that of healthy controls were evaluated.

Results: Plasma ferritin and hepcidin levels in T2DM group were higher than in the control group (P<0.05). The geometric mean±SD of hepcidin were 41.1±23.3 μg/l and 227.2±156.1 ng/l respectively; higher than the 15.2±2.3 μg/l and 114.4±60.4 ng/l of controls respectively. There was a significant associated between high level of plasma hepcidin (OR=2.75) and ferritin (OR=2.24); with T2 DM.

Conclusion: In conclusion: the regulation of body iron, an essential but also toxic element is strictly controlled by a small peptide hormone hepcidin. The present data demonstrated that the higher hepcidin level in diabetic patients may be due to that higher ferritin, the elevated hepcidin might have adaptive value through down-regulated iron absorb and play an important role in pathogenesis of T2 DM.

Keywords: Association, Ferritin, Hepcidin, Type 2 diabetes mellitus, Yemen.

INTRODUCTION

Type 2 diabetes mellitus (T2DM) is characterized by chronic hyperglycemia caused by impaired insulin secretion and/or insulin resistance¹. The role of micronutrients in the etiology of T2DM is not well established. Several lines of evidence suggest that iron play may a role in the pathogenesis of T2DM. Iron is an indispensable nutrient for the human body; it is essential to maintain systemic iron homeostasis because iron disorder in the body can lead to various clinical diseases². Recent facts suggest that increased body iron stores play a role in the pathogenesis of T2DM. Yeap et al.,³ detected serum ferritin, iron, and transferrin saturation among 1834 men and 2351 women and reported that higher serum ferritin levels were independently associated with T2DM. In view of the fact that ferritin is generally used as a marker of body iron stores, this study suggested that increased body iron stores is a risk factor for T2DM⁴. Excessive systemic iron can trigger oxidative stress injury in hepatocytes and pancreatic β cells, forming the basis of diabetes, which may cause insulin resistance, reduction in insulin secretion, and eventually, development of T2DM⁵,⁶. In addition, it has been reported that insulin can directly up-regulate hepcidin expression in hepatocellular carcinoma (HepG2) cells by enhancing signal transducers and activators of transcription 3 (STAT3) protein synthesis and DNA binding activity⁷, indicating that insulin disorder in T2DM can lead to inadequate hepcidin concentrations. Evidence suggests to us that insulin resistance accompanied by insufficient hepcidin levels can progress to overt diabetes through more dysfunction of cells via iron overload⁸. Hepcidin, a key hormone synthesized in the
liver, can regulate iron homeostasis; it can prevent iron efflux from macrophages, enterocytes and hepatocytes into the plasma by inducing internalization and degradation of the iron exporter ferroportin in these cells, which indicates that the iron overload is further aggravated by inadequate hepcidin in T2DM. Hepcidin expression can be regulated by iron-mediated pathways through signaling of JAK/STAT and BMP/SMAD. Iron stores can be detected using several techniques including liver biopsy, iron stains on bone marrow trephine biopsy, and serological detection. Serum ferritin level is now widely used in clinical practice and is considered the most convenient and cost-effective method to detect iron load. Also serum hepcidin has been proved to be an indicator of iron load. Moreover, the serum hepcidin/ferritin ratio has been used to evaluate iron metabolism of the body as it represents both body iron load and adequacy of hepcidin production for a given iron load. We aimed to assess iron, ferritin and hepcidin levels in serum of patients with or without T2DM and evaluated increased body iron stores as risk factor for developing T2DM. Since ferritin is commonly used as a marker of body iron stores.

SUBJECTS AND LABORATORY METHODS

Subject selection
After receiving approval from the Ethical Committee, we recruited 46 T2DM patients, and 42 healthy individuals; the age of the participants ranged 25–65 years. All participants provided a written informed consent, and all steps of the clinical examination and sampling procedures were explained to each participant. Participants were diagnosed with T2DM by specialist physicians at the hospital according to the American Diabetes Association criteria. Data regarding demographic and clinical characteristics, including age, body mass index (BMI), fasting blood glucose (FBG), triglyceride (TG), cholesterol (CHOL), high-density lipoprotein (HDL), low-density lipoprotein (LDL), alanine transaminase (ALT), and aspartate transaminase (AST), were recorded in physical examination reports of all participants.

Collection and storage of blood samples
Blood samples were collected from the antecubital fossa by venipuncture using a 20-gauge needle with a 5-mL syringe. All collections were performed by well-trained nurses at the nursing station. Plasma was separated from blood by centrifuging at 3000 rpm for 5 min. Blood samples which occurred hemolysis would be discarded. Each plasma sample was given a tracking number and stored at -20°C until further analysis.

Laboratory Tests
Ferritin and hepcidin were tested in serum samples using chemiluminescence microparticle immunoassay (CMI A) and enzyme-linked immunosorbent assay (ELISA) (Roche, Germany), respectively. The tests were performed according to the manufacturer’s instructions described in the assay procedure. A two-step immunoassay was required. Ferritin present in the sample binds to antiferritin-coated microparticles. After washing, antiferritin acridinium conjugate was added. Subsequently, pre-trigger and trigger solutions were added to the reaction mixture; the resulting chemiluminescent reaction was measured as relative light units (RLUs).

Data analysis
The analysis of data was done by Epi Info version 6 statistical program (CDC, Atlanta, USA), where the chi-square (q2) and probability value (p) was calculated for the test of significance by comparing the geometric mean±SD of the plasma level of ferritin, hepcidin, iron and insulin among cases (type 2 DM) comparing with that of healthy controls. In addition, Odd’s ratio (OR), 95% confidence interval (95% CI) were added to estimate the associated OR for high level of hepcidin, ferritin and iron with T2DM comparing with that of healthy controls. A p value < 0.05 was considered significant.

Ethical approval
We obtained written consent from all cases. Assent was taken from participants before collecting the specimens. The study proposal was evaluated and approved by the Ethics Committee of Faculty of Medicine and Health Sciences, Sana’a University.

RESULTS
Table 1 summarizes the demographic characteristics of study participants: the mean participant age in the T2DM and control groups was 25.5±2.8, 24.09±2.82 years, respectively. The age of T2DM patients ranged from 30 to 65 years, while for healthy control ranged from 25 to 56 years. The mean participant BMI (kg/m2) in the T2DM and control groups was 50.05±9.54 and 33.63±9.75 kg/m2 respectively. Fasting blood glucose levels were significantly higher in patients with T2DM than in those without T2DM (P < 0.05). However, no significant intergroup differences were noted in terms of sex, CHOL, HDL and LDL (P > 0.05) (Table 1).

Table 1: The comparison of parameters between type 2 DM and control groups.

| Biochemical parameters | Type 2 DM, n= 46 | Healthy control, n= 42 | P. value |
|------------------------|-----------------|------------------------|----------|
| BMI kg/m2              | Geometric mean±SD | Geometric mean±SD     |          |
| Age 25.45±2.8          | 30 – 65 years    | 24.91±2.82             | 30 – 56  | 0.908     |
| FBS mg/dl              | 219.8±73.8      | 128 – 400              | 95.2±7   | 82 – 108  | 0.001     |
| HDL mmol/l             | 1.06±0.32       | 0.5 – 2.5              | 1.06±0.2 | 0.7 – 1.7 | 0.908     |
| LDL mmol/l             | 3.1±0.81        | 1.7 – 5.2              | 2.91±0.8 | 1.3 – 4.6 | 0.394     |
| Triglycerides mmol/l   | 2.3±1.7         | 0.7 – 11.9             | 1.5±0.5  | 0.6 – 2.6 | 0.002     |
| T. cholesterol mmol/l  | 5.4±1.1         | 3.8 – 8.4              | 4.97±0.99 | 2.6 – 6.9 | 0.054     |
Table 2: The plasma level of hepcidin, ferritin, iron and insulin among cases (type 2 DM) and healthy controls.

| Biochemical parameters | Type 2 DM, n=46 | Healthy control, n=42 | P. value |
|------------------------|-----------------|-----------------------|----------|
|                        | Geometric mean±SD | Min–Max | Geometric mean±SD | Min–Max |         |
| Hepcidin μg/l | 41.1±23.3 | 17.2–76.9 | 15.2±2.3 | 10.2–19 | <0.001 |
| Ferritin ng/l | 227.2±156.1 | 30.3–638.3 | 114.4±60.4 | 20.2–258 | <0.001 |
| Iron μg/dl | 89.2±34.4 | 17.3–158 | 82.1±23.8 | 24.3–132 | 0.15 |
| Insulin μU/ml | 8.5±6 | 2–32.1 | 8.6±3.1 | 3.4–17.1 | 0.80 |

Table 2 shows the geometric mean±SD of the plasma level of hepcidin, ferritin, iron and insulin among T2DM comparing with that of healthy controls. The geometric mean±SD of hepcidin μg/l for DM patients were 41.1±23.3 μg/l higher than the 15.2±2.3 μg/l of healthy controls. In addition the hepcidin level for T2DM patients was ranged from 17.2 μg/l to 76.6 μg/l while for healthy controls was ranged from 10.2 μg/l to 19 μg/l only much lower than that of the T2 DM patients. The geometric mean±SD of ferritin ng/l for T2DM were 227.2±156.1 ng/l higher than the 114.4±60.4 ng/l of healthy controls. In addition the ferritin level for T2DM was ranged from 30.3 ng/l to 638.3 ng/l while for healthy controls was ranged from 20.2 ng/l to 258 ng/l lower than that of the T2DM. The geometric mean±SD of iron μg/dl for T2DM patients were 89.2±34.4 μg/l slightly higher than the 82.1±23.8 μg/dl of healthy controls. In addition the iron level for T2DM was ranged from 17.3 μg/dl to 158 μg/dl and for healthy controls was ranged from 24.3 μg/dl to 132 μg/dl slightly lower than that of the T2DM. The geometric mean±SD of insulin μU/ml for T2DM were 8.5±6 μU/ml is roughly similar to the 8.6±3.1 μU/ml of healthy controls. In addition the insulin level for T2DM was ranged from 2 μU/ml to 32.1 μU/ml and for healthy controls was ranged from 3.4 μU/ml to 17.1 μU/ml slightly lower than that of the T2DM. Table 3 shows the associated odds ratio of high levels of iron, hepcidin, ferritin, and insulin in T2 DM comparing with healthy controls. There was a significant associated Odds ratio between high level of plasma iron and type 2 DM in which the associated OR is equal to 1.98 times, with 95% CI=1.6–24, χ²=3.9 and p=0.05. Also, there was a significant associated Odds ratio between high level of plasma hepcidin and type 2 DM in which the associated OR=2.75 with 95% CI=2–3.8, χ²=26.7 and p<0.001. Additionally, there was a significant associated Odds ratio between high level of plasma ferritin and T2DM in which the associated OR=2.24, 95%CI=1.74–2.9, χ²=12.7 and p<0.001. As well, there was a non-significant associated Odds ratio between high level of plasma insulin and type 2 DM (OR=3.9, p=0.2).

DISCUSSION
Diabetes Mellitus is a predominant public health concern, affecting millions of people worldwide. The disease causes substantial morbidity and mortality and long term complications. In the last 15 years, it is recognized that, increased body iron stores are associated with the development of Glucose intolerance, gestational diabetes and Type-2 diabetes. The aim of current study was to confirm the association of increased plasma iron, hepcidin, and ferritin level with the development of glucose intolerance and Type-2 diabetes comparing with plasma iron, hepcidin, and ferritin level of healthy controls. In current study there was a significant association between high level of serum iron concentration (>150 μg/dl) with DM by means of associated odds ratio equal to 1.98, comparing with healthy controls (p=0.05). This result is similar to that reported by Wrede et al.,17 and Cavallo et al.,18 in which increased serum iron negatively correlate with insulin sensitivity and the presence of insulin resistance syndrome. This negative correlation can be explained by the significant tissue accumulations of iron can lead to pathology in the liver, heart, endocrine organs, and musculoskeletal system.14 Excess iron deposition in the pancreas is known to cause a secondary form of diabetes, which has lead to speculation that higher concentrations of iron may increase the risk of developing diabetes. Earlier studies provided mixed evidence in support of the iron–diabetes hypothesis, and consequently the hypothesis was largely dismissed.19 The existence of an iron regulatory hormone was postulated primarily to account for the observed interactions between the anatomically distinct sites of iron absorption, recycling and utilization.

Hepcidin is now acknowledged to be the main iron regulatory hormone. It is a 25-amino acid peptide exclusively synthesized by the liver, initially identified as part of a search for novel antimicrobial peptides.20,21 There was no indication that it had an additional role in iron metabolism until 2001, when mouse studies were published showing that hepatic hepcidin mRNA synthesis was induced by iron loading.22,23 In current study there was a highly significant association between high level of serum hepcidin concentration (>75 μg/dl) with T2DM by means of associated odds ratio equal to 2.75 (95% CI=2–3.78) times comparing with healthy controls, with χ² equal to 26.7, and p value less than 0.001 (Table 3). This result is similar to that reported by Darshan and Anderson in which increased serum hepcidin is correlated with DM type 2 and insulin resistance DM cases. The association Hepcidin with DM and iron concentration can be explained by that the rate of iron efflux into the plasma depends primarily on the plasma level of hepcidin; when iron levels are high the synthesis of hepcidin increases and the release of iron from enterocytes and macrophages are diminished.
Conversely when iron stores drop, the synthesis of hepcidin is down-regulated and these cells release more iron. What's more, in current study there was a significant association between high level of serum ferritin concentration (>600 ng/dl) with T2DM by means of associated odd's ratio equal to 2.24(p< 0.001) comparing with healthy controls. This result is similar to that reported by Redmon et al. and Fleming in which increased serum ferritin is correlated with DM type 2 and insulin resistance DM cases.

Serum ferritin (SF) has been reported to negatively correlate with insulin sensitivity and the presence of insulin resistance syndrome. Furthermore insulin resistance, compensated by Hyperinsulinaemia, sets in early even before the onset of frank diabetes mellitus and correlate well with indicators of iron overload and SF. Additionally other evidence clear the effect of ferritin on iron overload and the encouraging development of DM type 2 is that frequent blood donation lead to decrease iron stores, which in turn reduces post-prandial Hyperinsulinaemia in healthy volunteers and improves insulin sensitivity. Insulin resistance, correlate well with total units of blood transfused, splenomegaly and SF in chronically transfused patients of thalassemia major. Also, phlebotomy is followed by drop in serum glucose, serum Cholesterol, serum triglycerides and improvement in both beta cell secretion and peripheral insulin action in type-2 diabetes mellitus. As well epidemiological studies suggest that high body iron stores are associated with insulin resistance and type 2 diabetes with high level of serum ferritin. Also current study’s result is suggested that 26.1% (Table 3) of T2DM patients (might developed IRS (Insulin Resistance Syndrome) this suggestion supported by Wrede et al., which reported a significant correlation between SF and the presence of IRS criteria in a large representative population. Fernandez-Real et al. found that in general population increased body iron stores are possibly associated with occurrence of glucose intolerance, type-2 diabetes and gestational diabetes. Facchini found significant reduction in serum insulin concentration after performing a 550 ml phlebotomy in healthy volunteers. Bloodletting of 1500 ml has been demonstrated to improve insulin sensitivity and to decrease C-peptide secretion in type-2 diabetes subjects who had decreased SF concentration. Similarly Dmochowski et al. and Jehn et al. reported in a study on thalassemic patients that SF concentration correlated negatively with insulin sensitivity and the conclusion of the study showed a major and significant insulin resistance which may be compensated for by an elevated circulating insulin level. Dymock et al. and Swaminathan et al. reported significant reduction in total daily insulin dosage following phlebotomy and improvement in diabetic status of patients following venesection.

### Table 3: The associated odds ratio of high iron, hepcidin, ferritin, insulin, in type 2 DM comparing with healthy controls.

| Biochemical parameters | High level DM | High level control | OR   | CI   | χ² | P   |
|------------------------|--------------|--------------------|------|------|----|-----|
| Iron µg/dl              | 3            | 6.5                | 0    | 1.98 | 1.6-24 | 3.9 | 0.05 |
| Hepcidin µg/l           | 22           | 48                 | 0    | 2.75 | 2.3-3.8 | 26.7 | <0.001 |
| Ferritin ng/l           | 12           | 26.1               | 0    | 2.24 | 1.74-2.9 | 12.7 | <0.001 |
| Insulin µU/ml           | 4            | 8.7                | 1    | 2.4  | 3.9   | 0.4-95.8 | 1.63 | 0.2 |

OR-Odds ratio= Relative risk, CI- Confidence intervals. χ²-Ci-square= 3.9 or more significant, p= Probability value= 0.05 or less significant.
elevated hepcidin in Type 2 DM patients may be due to those elevated ferritin levels, and this confirmed with study of Fang Jiang, et al. 48. The confirmation of an increased risk of diabetes with moderately elevated ferritin levels could have clinical and public health consequences, since persons at high risk could be targeted for more intensive screening and preventive interventions. From these points, the elevated hepcidin concentrations may have adaptive value through down-regulated iron absorb in patients with Type 2 DM. Hepcidin concentration may be useful to predict which patients could benefit from it although the potential use of hepcidin targeted therapeutics are yet available.

CONCLUSION
The geometric mean±SD of the plasma level of hepcidin, ferritin, iron and insulin among cases (type 2 DM) were higher than that of healthy controls. The regulation of body iron, an essential but also toxic element is strictly controlled by a small peptide hormone hepcidin. The present data demonstrated that the higher hepcidin level in diabetic patients may be due to that higher ferritin, the elevated hepcidin might have adaptive value through down-regulated iron absorb and play an important role in pathogenesis of type 2 DM.

RECOMMENDATION
A wider knowledge of hepcidin regulation will provide us with novel tools for differential diagnosis, therapeutic regimes and monitoring of disorders of iron metabolism. However, a lot remains to be uncovered on the biology and function of hepcidin. Its signaling pathways are as yet to be delineated. Further studies are needed to define precisely the hepcidin role in iron metabolism homeostasis and its utility in the diagnosis and treatment of iron disorders. Also that more studies need to be performed regarding the role of ferritin in pre-diabetic stage as well as in type 2 diabetics. Finally prospective studies are needed to confirm whether elevated serum ferritin predicts insulin resistance and its associated conditions, or is merely a secondary marker of metabolic abnormalities.
