Abstract. 6-Benzyladene (6-BA) is a safe and efficient cytokinin. The adult tea plants of the cv. Longjing 43 were used in this study. The foliar portion of tea bushes were sprayed with different concentrations (50, 100, 200, or 400 mg·L⁻¹) of 6-BA after heavy pruning, when three to four leaves grew out in late May. The effects of 6-BA application on the growth of the new shoots and lateral branches were quantified. After 5 months, treatments with 50, 100, 200, or 400 mg·L⁻¹ 6-BA suppressed plant height by 11.0%, 18.0%, 21.0%, or 22.0%, respectively; 6-BA at 100, 200, or 400 mg·L⁻¹ decreased the number of lateral branches by 20.0%, 23.0%, or 18.0%, respectively. Meanwhile, treatments with 50, 200, or 400 mg·L⁻¹ 6-BA increased the length of lateral branches by 38.0%, 79.0%, or 81.0% respectively; 200 mg·L⁻¹ 6-BA increased the diameter of lateral branches by 8.0%. In addition, after 2 months, 50 or 200 mg·L⁻¹ 6-BA did not significantly affect the growth of functional leaves, 50, 100, or 200 mg·L⁻¹ 6-BA did not significantly affect photosynthetic rate (Pn) as compared with the control. Furthermore, 200 or 400 mg·L⁻¹ 6-BA significantly increased spring tea yield by 28.9% or 38.0%, 79.0%, or 81.0% respectively as compared with the control. In conclusion, 6-BA at the four concentrations promoted dwarfing and the formation of productive lateral branches and increased the spring yield, and 200 mg·L⁻¹ 6-BA exerted the best comprehensive effect.
Meiling South Road, Xihu District, Hangzhou, Zhejiang province, China (lat. 30°140′N and long. 120°100′E, 16 m above sea level).

Different concentrations of 6-BA working solution (50, 100, 200, and 400 mg L⁻¹; J&K Scientific Ltd., China) were prepared by adding solute in distilled H₂O followed by adding 1.0% hydrochloride, and the mixture was stirred until dissolution. Nonionic surfactant was added before spraying. Control (0 mg L⁻¹) tea bushes were simultaneously sprayed with distilled H₂O containing the same ratio of hydrochloride and nonionic surfactant. Each treatment comprises three replications, and each replication spans an area of 10 m² consisting of 20 tea bushes. For the present study, tea plants that were heavily pruned in late April were chosen. When the apical buds and three to four leaves below the bud grew out in late May, the foliar portion of tea bushes was sprayed with different concentrations of 6-BA solution.

**Index measurement and methods.** The plant height, the number of lateral buds (or branches), and the length of new shoots, internodes, and lateral buds (or branches) were measured 1, 2, and 5 months after 6-BA application. The new shoots refer to the new branches sprouting from the main shoots after heavy pruning in summer. The length of all the internodes on one new shoot was measured and the average length was used as a replication. The diameter of all the lateral branches on one new shoot was measured using a vernier caliper and the average diameter was used as a replication. For each treatment, 15–30 new shoots, lateral branches on one new shoot was used as a replication. The diameter of all the lateral branches on one new shoot was measured using a vernier caliper and the average diameter was used as a replication. For each treatment, 15–30 new shoots, lateral buds (or branches), or tea bushes were tested.

At 1 and 2 months after 6-BA application, Pn was measured on the third fully expanded leaves in 12 tea bushes under each treatment by using an open-flow infrared gas analyzer adapted with light and temperature control systems (Li-COR 6400; Lincoln, NE). The measurement was performed within the time period from 8:00 AM to 11:00 AM maintaining the air temperature, relative humidity, CO₂ concentration, and photosynthetic photon flux density at 25 °C, 80.0%, 400 μmol mol⁻¹ and 800 μmol m⁻² s⁻¹, respectively.

The leaf area of the third fully expanded leaves was measured using a portable leaf area meter (LI-3000C; LI-COR, Lincoln, NE), and five to six replications (with one leaf in each shoot as a replication) were measured for each treatment. A square frame with 0.1 m² area was made using a hard iron wire. The number of leaf buds in the range of the square frame was counted and the density of bud (bud/m²) was calculated. Meanwhile, the 100 buds and leaf buds in the range of the square frame were weighted and the yield (g/m²) was calculated.

**Statistical analysis.** Data were analyzed using Statistica (SAS Institute, Inc., Cary, NC, http://www.statsoft.com). In each figure and Table 1, the differences of each index among different concentrations of 6-BA application at each time point were analyzed using one-way analysis of variance (ANOVA); if the ANOVA analysis was significant (P < 0.05), Duncan’s multiple range test was used to detect significant differences between means.

**Results**

**Effect of 6-BA on the plant height and the number of lateral buds (or branches) of tea plants.** After 1 month, the height of tea plants treated with 50, 100, 200, or 400 mg L⁻¹ 6-BA decreased by 4.7%, 11.3%, 11.8%, or 16.0%, respectively. After 2 months, it decreased by 6.2%, 13.7%, 15.4%, or 18.7%, respectively. After 5 months, it decreased by 11.0%, 17.8%, 20.6%, or 22.2%, respectively (Fig. 1A). At 1, 2, and 5 months after 6-BA application, the height of tea plants sprayed with the four concentrations of 6-BA was significantly lower than that of the control plants, and the degree of inhibition increased with increasing 6-BA concentration.

Treatment with 50, 100, 200, or 400 mg L⁻¹ 6-BA for 1 month increased the number of lateral buds by 97.0%, 142.0%, 162.0%, or 172.0%, respectively, compared with the control. This result indicates that the degree of increase in the number of lateral buds under 6-BA treatment is highly concentration specific. After 2 months, the number of lateral buds increased with increasing 6-BA concentrations, but no significant difference was observed among the four treatments. After 5 months, treatment with 100, 200, or 400 mg L⁻¹ 6-BA decreased the number of lateral branches by 20.0%, 23.0%, or 18.0%, respectively, and 6-BA at 50 mg L⁻¹ did not significantly affect the number of lateral branches as compared with the control (Fig. 1B).

**Effect of 6-BA on the growth of new shoots and lateral branches of tea plants.** As shown in Fig. 1, the effect of 6-BA on the growth of new shoots and lateral branches of tea plants was concentration dependent. The number of lateral branches as compared with the control (Fig. 1B).

**Table 1. Effects of 6-Benzyladenine (6-BA) on the growth and yield of spring tea.** Tea bushes were sprayed with 50, 100, 200, or 400 mg L⁻¹ 6-BA solution. Control (0 mg L⁻¹ 6-BA) tea bushes were simultaneously sprayed with distilled H₂O. The density of bud, weight of 100 buds, and yield were measured in early April of the following spring. Data shown were means ± SE (n = 6). Letters indicate significant differences in each index among different concentration of 6-BA application (P < 0.05, Duncan’s multiple range test).

| 6-BA concn (mg·L⁻¹) | Density of bud (bud/m²) | Wt of 100 buds (g) | Yield (g/m²) |
|---------------------|------------------------|-------------------|--------------|
| 0                   | 2.380 ± 240.2 a        | 5.80 ± 0.136 b    | 143.9 ± 16.86 a |
| 50                  | 2.523 ± 164.4 ac       | 6.30 ± 0.46 ab    | 166.8 ± 13.57 ab |
| 100                 | 2.703 ± 155.3 bc       | 6.78 ± 0.171 ac   | 181.7 ± 10.26 ab |
| 200                 | 2.957 ± 127.1 b        | 7.42 ± 0.523 c    | 185.5 ± 6.90 b  |
| 400                 | 2.723 ± 208.4 bc       | 6.53 ± 0.608 a    | 163 ± 8.94 ab   |

Fig. 1. Effect of different concentrations of 6-Benzyladenine (6-BA) on the height (A) and the number of lateral buds or branches (B) of tea plants. Tea bushes were sprayed with 50, 100, 200 or 400 mg L⁻¹ 6-BA solution. Control (0 mg L⁻¹ 6-BA) tea bushes were simultaneously sprayed with distilled H₂O. The indexes in each figure were measured at 1, 2, and 5 months after 6-BA application. Error bars indicate SE. Letters indicate significant differences in each index among different treatment at each time point (P < 0.05, Duncan’s multiple range test).
in Fig. 2A, the different concentrations of 6-BA significantly inhibited new shoot growth after 1 and 2 months. Moreover, the degree of inhibition of 100 and 200 mg·L⁻¹ 6-BA was significantly greater than that of 50 mg·L⁻¹ 6-BA, no significant differences were noted between 100 and 200 mg·L⁻¹ 6-BA, and 400 mg·L⁻¹ 6-BA had the strongest effect. After 5 months, 50, 100, 200, or 400 mg·L⁻¹ 6-BA application reduced new shoot length by 13.0%, 15.0%, 25.0%, or 28.0%, respectively, as compared with the control. This result implies that the inhibition degree of 6-BA on new shoot growth increased with increasing 6-BA concentration after 5 months. Moreover, 400 mg·L⁻¹ 6-BA inhibited new shoot growth excessively and there were excessive and finer lateral branches after 400 mg·L⁻¹ 6-BA treatment for 5 months.

After 1 month, 400 mg·L⁻¹ 6-BA significantly reduced the internode length of new shoots by 5.1% as compared with the control, whereas no significant differences were noted among the other four treatments. The internode lengths of the tea plants treated with 100, 200, or 400 mg·L⁻¹ 6-BA were significantly shorter than those of the control plants after 2 months. After 5 months, 50, 200, or 400 mg·L⁻¹ 6-BA significantly reduced the internode length by 17.0%, 20.0%, or 21.0%, respectively (Fig. 2B). After 1 and 2 months, the lateral bud (or branch) lengths of the tea plants treated with 100, 200, or 400 mg·L⁻¹ 6-BA significantly increased compared with that of the control plants. At 5 months after 6-BA application, the lateral branches of the tea plants treated with 50, 200, or 400 mg·L⁻¹ 6-BA were 38.0%, 79.0%, or 81.0% longer than that of the control plants, respectively (Fig. 2C). At the same period, 200 mg·L⁻¹ 6-BA significantly increased the lateral branch diameter by 7.5% as compared with the control, whereas no significant differences were noted among the other four treatments (Fig. 2D).

Effect of 6-BA on the growth of tea leaves. The leaf areas of the third fully expanded leaves were measured using a portable leaf area meter. As shown in Fig. 3A, the leaf areas treated with 50, 100, 200, or 400 mg·L⁻¹ 6-BA reduced by 37.0%, 40.0%, 52.0%, or 54.0% after 1 month, respectively, compared with those of the control plants. Hence, the inhibition degree of 6-BA strengthened with increasing concentration. After 2 months, 100 or 400 mg·L⁻¹ 6-BA significantly inhibited leaf growth when compared with the control, whereas no significant differences in leaf areas were noted among the other three treatments.

Effect of 6-BA on Pn in tea plants. To understand the photosynthetic response of tea plants to 6-BA, the Pn of the third fully expanded leaves was determined after 6-BA treatment. As shown in Fig. 3B, 50, 100, 200, or 400 mg·L⁻¹ 6-BA application for a month suppressed Pn in tea plants by 13.0%, 16.0%, 16.0%, or 16.0%, respectively, as compared with the control. However, except for 400 mg·L⁻¹ 6-BA, the other three concentrations of 6-BA treatment did not significantly affect Pn as compared with the control after 2 months.

The aforementioned results suggest that the changes induced by 6-BA application on the leaf areas and Pn of the third fully expanded leaves show similar trends. Thus, the decreased Pn after 6-BA treatment may
be partly because of the inhibited leaf growth after 1 month of 6-BA application. Considering that the unpruned tea plants have stopped growing and no new shoots appeared in November, we did not measure the leaf area and Pn after 5 months of 6-BA application. Thus, except for the inhibition of 400 mg L⁻¹ 6-BA on Pn, the other three concentrations of 6-BA did not significantly affect Pn of functional leaves after 2 months as compared with the control.

Effect of 6-BA on spring tea yield. To assess the effect of 6-BA treatment on growth and biomass production in tea plants, we measured the leaf mass, density of tea bud, weight of 100 buds, and spring tea yield in early April of the following spring. The results showed that there were no significant differences in the leaf mass among different treatments (data not shown). The density of tea buds increased with 100, 200 or 400 mg L⁻¹ 6-BA, among which 200 mg L⁻¹ 6-BA had the strongest effect. Likewise, weight of 100 buds showed an increased value under 100, 200 or 400 mg L⁻¹ 6-BA treatment, where 200 mg L⁻¹ 6-BA had the greatest effect. Similar to the trends in density of bud, 200 or 400 mg L⁻¹ 6-BA treatment significantly increased the yield by 28.9% or 13.3%, respectively, as compared with the control (Table 1).

Discussion

Shoot branching is an important agronomic trait that determines the plant morphology aboveground, thereby affecting crop yield and quality (Chen et al., 2016; Muhr et al., 2016). The occurrence, development, and regulatory factors of shoot branching have been widely studied in the recent decades, however, these studies mainly focused on herbaceous plants, such as rice (Oryza sativa), maize (Zea mays), Arabidopsis (Arabidopsis thaliana), pea (Pisum sativum), petunia (Petunia axillaris), and tomato (Solanum lycopersicum) (Dun et al., 2012; Li et al., 2003), and rarely on woody plants.

Plant growth regulators are usually used to promote shoot branching in fruit production (Kender and Carpenter, 1972). For example, exogenous application of morphactin can break the lateral bud dormancy of citrus seedlings, promote dwarfing and produce bushy young apple trees (Roversi, 1971). Gibberellins stimulate axillary bud activity and inhibit the extension growth of the apical meristems of tea plant (Kagira, 1975; Liang et al., 1997; Maudu et al., 2011). Cytokinins are a class of plant hormones that play key roles in regulating plant cell division and development (Kakimoto, 2003; Sakakibara et al., 2006; Werner et al., 2001, 2003). They are reportedly involved in the outgrowth and dormancy of lateral buds (Hitoshi et al., 2006; Sachs and Thimann, 1967) and exogenous cytokinin application could promote the occurrence and growth of axillary buds (Anger et al., 1973; Chaffield et al., 2000; Liu et al., 2009). 6-Benzyladenine is a cytokinin-like substance that is widely applied in agriculture production at present. Exogenous 6-BA application could promote the growth of lateral buds and lateral branches (Elfving and Visser, 2006; Oono et al., 2005).

The apical dominance of tea plant is obvious and its growth must be controlled artificially to promote the formation of new shoots. In the present study, different concentrations of 6-BA were sprayed to heavily pruned, mature tea plants when three to four leaves grew out in late May. The results showed that four concentrations of 6-BA significantly inhibited new shoot growth (i.e., promoted dwarfing) and increased the number of lateral buds after 1 month but decreased the number of lateral branches after 5 months. 6-Benzyladenine treatment also increased the length of lateral buds (or branches) and the diameter of lateral branches after 5 months. In the later stage, 6-BA treatment may promote the transferring of more nutrition into sprouting lateral buds as compared with the control, thus promoting the growth of lateral branches and inhibiting late lateral budbreaking. So it is concluded that 6-BA treatment can promote early lateral bud release and productive lateral branch formation, and inhibit invalid lateral branch formation. Among the four concentrations, 200 mg L⁻¹ 6-BA exhibited the best comprehensive effect. Consistent with this study, previous studies reported that 6-BA application promotes axillary bud outgrowth and lateral branch growth in different plants. For example, 6-BA application to axillary buds inhibits shoot growth and induces branching of peas (Sprent, 1967). 6-Benzyladenine treatment stimulates the breaking of rice tiller buds (Liu et al., 2009).

In addition, the present study showed that 6-BA application did not significantly affect the growth and Pn of functional leaves. Furthermore, different concentrations of 6-BA treatment significantly increased spring tea yield and among which 200 mg L⁻¹ 6-BA exerted the best comprehensive effect. Therefore, it can be concluded that exogenous 6-BA application may enhance the photosynthetic performance of colony leaves by increasing the number of productive lateral branches and functional leaves. Thus, this treatment helps increase spring tea yield of tea plants.

In summary, the results of this study showed that foliage spraying of a suitable concentration of 6-BA after heavy summer pruning could inhibit overgrowth of the tea plant, promote formation of productive lateral branches, and increase spring tea yield of Longjing 43 adult tea plants. It is concluded that for shrub-type adult tea garden in which only spring tea was picked up, tea plants usually need pruning twice every year, thus 6-BA application could avoid autumn pruning and promote the continuous growth of tea plants, thereby saving assimilation product, reducing labor cost, and avoiding pruning-induced diseases.
It is suggested to spray the adult tea plants of the cv. Longjing 43 with 200 mg·L⁻¹ 6-BA after heavy pruning in summer, when the axillary buds grow out three to four leaves, which could reduce labor cost and improve labor efficiency. For shrub-type adult tea garden in which only spring tea was picked up, the results of this study can serve as a theoretical basis for providing a novel strategy for tea cultivation management, thus avoiding pruning in autumn once a year. The developed technique can also be applied to the different tea varieties with similar branching characteristics when grown in regions with similar site conditions. However, the promotion effects of 6-BA on dwarfing and lateral shoot formation in other tea plant varieties grown under different site conditions need further study.
