Abstract
It is shown that, for each $d \geq 4$, there exists an integral convex polytope $P$ of dimension $d$ such that each of the coefficients of $n, n^2, \ldots, n^{d-2}$ of its Ehrhart polynomial $i(P, n)$ is negative. Moreover, it is also shown that for each $d \geq 3$ and $1 \leq k \leq d - 2$, there exists an integral convex polytope $P$ of dimension $d$ such that the coefficient of $n^k$ of the Ehrhart polynomial $i(P, n)$ of $P$ is negative and all its remaining coefficients are positive. Finally, we consider all the possible sign patterns of the coefficients of the Ehrhart polynomials of low dimensional integral convex polytopes.

Keywords Integral convex polytope · Ehrhart polynomial · Positivity problem for combinatorial polynomials

1 Introduction

A convex polytope is called \textit{integral} if any of its vertices has integer coordinates. Let $P \subset \mathbb{R}^N$ be an integral convex polytope of dimension $d$. We define the function
i(\mathcal{P}, n) by setting
\[ i(\mathcal{P}, n) = \#(n\mathcal{P} \cap \mathbb{Z}^N) \quad \text{for} \quad n = 1, 2, \ldots, \]

where \( n\mathcal{P} = \{ n\alpha : \alpha \in \mathcal{P} \} \) and \( \#X \) is the cardinality of a finite set \( X \). The study on \( i(\mathcal{P}, n) \) originated with Ehrhart [2] who proved that \( i(\mathcal{P}, n) \) is a polynomial in \( n \) of degree \( d \) with the constant term 1. Furthermore, the coefficients of \( n^d \) and \( n^{d-1} \) of \( i(\mathcal{P}, n) \) are always positive [1, Corollary 3.20 and Theorem 5.6]. We say that \( i(\mathcal{P}, n) \) is the Ehrhart polynomial of \( \mathcal{P} \).

In his talk of the Clifford Lectures at Tulane University, 25–27 March 2010, Richard Stanley gave an Ehrhart polynomial with a negative coefficient. More precisely, the polynomial \( \frac{13}{6}n^3 + n^2 - \frac{1}{6}n + 1 \) is the Ehrhart polynomial of the tetrahedron in \( \mathbb{R}^3 \) with vertices \((0, 0, 0), (1, 0, 0), (0, 1, 0) \) and \((1, 1, 13)\). See [1, Example 3.22]. His talk naturally inspired us to find integral convex polytopes of dimension \( \geq 4 \) whose Ehrhart polynomials possess negative coefficients. Consult [3, Part II] and [4, pp. 235–241] for fundamental materials on Ehrhart polynomials.

The primary purpose of the present paper is, for each \( d \geq 4 \), to show the existence of an integral convex polytope of dimension \( d \) such that each of the coefficients of \( n, n^2, \ldots, n^{d-2} \) of its Ehrhart polynomial \( i(\mathcal{P}, n) \) is negative.

**Theorem 1.1** Given an arbitrary integer \( d \geq 4 \), there exists an integral convex polytope \( \mathcal{P} \) of dimension \( d \) such that each of the coefficients of \( n, n^2, \ldots, n^{d-2} \) of the Ehrhart polynomial \( i(\mathcal{P}, n) \) of \( \mathcal{P} \) is negative.

This theorem says that all coefficients of Ehrhart polynomials can be negative except for the coefficients of \( n^d \) and \( n^{d-1} \) and the constant term which are always positive.

The second purpose of the present paper is the study of the sign patterns of the coefficients of the Ehrhart polynomials of integral convex polytopes. In the present paper, as a further investigation on the signs of the coefficients of Ehrhart polynomials, we prove the following theorem.

**Theorem 1.2** Given arbitrary integers \( d \) and \( k \) with \( 1 \leq k \leq d - 2 \), there exists an integral convex polytope \( \mathcal{P} \) of dimension \( d \) such that the coefficient of \( n^k \) of \( i(\mathcal{P}, n) \) is negative and all its remaining coefficients are positive.

Finally, we also consider all the possible sign patterns of the coefficients of the Ehrhart polynomials of low dimensional integral convex polytopes (Proposition 4.2).

### 2 The Existence of Ehrhart Polynomials with Negative Coefficients

In this section, we prove Theorem 1.1. First, we collect some examples (Examples 2.1 and 2.2) which we will use in the proofs of Theorems 1.1, 1.2 and Proposition 4.2.

**Example 2.1** Let \( m \) be an arbitrary positive integer and let
\[ \ell_m = \{ \alpha \in \mathbb{R} : 0 \leq \alpha \leq m \}. \]
Note that this \( \ell_m \) is nothing but an integral convex polytope of dimension 1. Then the Ehrhart polynomial \( i(\ell_m, n) \) is equal to \( mn + 1 \).

**Example 2.2** It is known [1, Example 3.22] that given an arbitrary integer \( m \geq 1 \), there exists an integral convex polytope \( Q^{(3)}_m \) of dimension 3 with

\[
i(Q^{(3)}_m, n) = \frac{m}{6} n^3 + n^2 + \frac{-m + 12}{6} n + 1.
\]

Next, we recall the following well-known fact.

**Lemma 2.3** Let \( f_1(n) \) and \( f_2(n) \) be the Ehrhart polynomials of some integral convex polytopes of dimension \( d_1 \) and \( d_2 \), respectively. Then there exists an integral convex polytope of dimension \( d_1 + d_2 \) whose Ehrhart polynomial is equal to \( f_1(n) \cdot f_2(n) \).

**Proof** Take the direct product of two integral convex polytopes. \( \square \)

Our proof of Theorem 1.1 will be given after preparing Lemma 2.4.

**Lemma 2.4** Let \( d \) and \( j \) be integers with \( d \geq 5 \) and \( 3 \leq j \leq d - 2 \), and

\[
g(d, j) = (d - 3)^2 \binom{d - 3}{j - 1} - \binom{d - 3}{j - 3}.
\]

Then one has \( g(d, j) > 0 \).

**Proof** Since \( d \geq 5 \), one has \( g(d, 3) = (d - 3)^2 \frac{(d - 3)}{2} - 1 > 0 \) and \( g(d, d - 2) = (d - 3)^2 - \frac{(d - 3)}{2} > 0 \). Thus \( g(d, j) > 0 \) for \( j = 3 \) and \( j = d - 2 \). In particular, the assertion is true for \( d = 5 \) and \( d = 6 \).

We now work with induction on \( d \). Let \( d \geq 7 \) and \( 4 \leq j \leq d - 3 \). Then

\[
g(d, j) = ((d - 4)^2 + 2d - 7) \left( \binom{d - 4}{j - 1} + \binom{d - 4}{j - 2} \right) - \left( \binom{d - 4}{j - 3} + \binom{d - 4}{j - 4} \right)
\]

\[
= g(d - 1, j) + g(d - 1, j - 1) + (2d - 7) \binom{d - 3}{j - 1}.
\]

It follows from the assumption of induction that \( g(d - 1, j) + g(d - 1, j - 1) > 0 \). Hence \( g(d, j) > 0 \), as desired. \( \square \)

Now, we prove Theorem 1.1.

**Proof of Theorem 1.1** Given an arbitrary integer \( d \geq 4 \), from Examples 2.1 and 2.2, and by applying Lemma 2.3 repeatedly, there exists an integral convex polytope \( P^{(d)}_m \) of dimension \( d \) such that

\[
i(P^{(d)}_m, n) = i(\ell_{d-3}, n)^{d-3} \cdot i(Q^{(3)}_m, n)
\]

\[
= ((d - 3)n + 1)^{d-3} \left( \frac{m}{6} n^3 + n^2 + \frac{-m + 12}{6} n + 1 \right).
\]
Let $i(P_m^{(d)}, n) = \sum_{i=0}^{d} c_i^{(d,m)} n^i$ with each $c_i^{(d,m)} \in \mathbb{Q}$. Then

$$c_1^{(d,m)} = \frac{-m + 12}{6} + A_1, \quad c_2^{(d,m)} = 1 + \frac{-m + 12}{6} A_1 + A_2$$

and

$$c_j^{(d,m)} = \frac{m}{6} A_{j-3} + A_{j-2} + \frac{-m + 12}{6} A_{j-1} + A_j, \quad 3 \leq j \leq d - 2,$$

where

$$A_i = (d - 3)^i \binom{d - 3}{i}, \quad 0 \leq i \leq d - 2.$$

Now, since each $A_j$ is independent of $m$, it follows that each of $c_1^{(d,m)}$ and $c_2^{(d,m)}$ is negative for $m$ sufficiently large. Let $3 \leq j \leq d - 2$. One has

$$c_j^{(d,m)} = -A_{j-1} - A_{j-3} m + (A_{j-2} + 2 A_{j-1} + A_j)$$

$$= -(d - 3)^{j-3} g(d, j) m + (A_{j-2} + 2 A_{j-1} + A_j),$$

where $g(d, j)$ is the same function as in Lemma 2.4. Since $g(d, j) > 0$, it follows that $c_j^{(d,m)}$ can be negative for $m$ sufficiently large. Hence, for $m$ sufficiently large, the integral convex polytope $P_m^{(d)}$ of dimension $d$ enjoys the required property. \hfill \Box

We conclude this section with

**Remark 2.5** The polynomial

$$i(Q_m^{(3)}, n) = \frac{m}{6} n^3 + n^2 + \frac{-m + 12}{6} n + 1$$

$$= \frac{1}{6} (n + 1) (mn^2 + (6 - m)n + 6)$$

has a real positive zero for $m$ sufficient large. Hence $i(P_m^{(d)}, n)$ has a real positive zero for $m$ sufficient large.

Thus in particular, for $m$ sufficient large and for an arbitrary integral convex polytope $Q$, the Ehrhart polynomial $i(P_m^{(d)} \times Q, n)$ of $P_m^{(d)} \times Q$ also possesses a negative coefficient.

We are grateful to Richard Stanley for his suggestion on real positive roots of Ehrhart polynomials.
3 Ehrhart Polynomials Having Only One Negative Coefficient

In this section we prove Theorem 1.2. Let $e_i^d$ be the $i$th unit coordinate vector of $\mathbb{R}^d$ for $1 \leq i \leq d$ and let $0^d$ be the origin of $\mathbb{R}^d$. First, we give the following example.

**Example 3.1** (a) Let

$$
\mathcal{P}^{(4)} = \text{conv} \left( \{0^4, e_1^4, e_2^4, e_3^4, e_4^4 + 26e_3^4 + 27e_4^4\} \right) \subset \mathbb{R}^4.
$$

Then we have

$$i(\mathcal{P}^{(4)}, n) = \frac{9}{8}n^4 + \frac{31}{12}n^3 + \frac{3}{8}n^2 - \frac{1}{12}n + 1.
$$

(b) Let

$$
\mathcal{P}^{(5)} = \text{conv} \left( \{0^5, e_1^5, e_2^5, e_3^5, e_4^5, e_5^5 + 50e_4^5 + 51e_5^5\} \right) \subset \mathbb{R}^5.
$$

Then we have

$$i(\mathcal{P}^{(5)}, n) = \frac{13}{30}n^5 + \frac{55}{24}n^4 + \frac{37}{12}n^3 + \frac{5}{24}n^2 - \frac{1}{60}n + 1.
$$

We also prepare the following two lemmas (Lemmas 3.2 and 3.3).

**Lemma 3.2** Given an arbitrary integer $d \geq 3$, there exists an integral convex polytope $\mathcal{P}$ of dimension $d$ such that the coefficient of $n$ of $i(\mathcal{P}, n)$ is negative and all its remaining coefficients are positive.

**Proof** From Examples 2.2 and 3.1, we have

$$
i(Q^{(3)}_{13}, n) = \frac{13}{6}n^3 + n^2 - \frac{1}{6}n + 1;
$$

$$i(\mathcal{P}^{(4)}, n) = \frac{9}{8}n^4 + \frac{31}{12}n^3 + \frac{3}{8}n^2 - \frac{1}{12}n + 1;
$$

$$i(\mathcal{P}^{(5)}, n) = \frac{13}{30}n^5 + \frac{55}{24}n^4 + \frac{37}{12}n^3 + \frac{5}{24}n^2 - \frac{1}{60}n + 1.
$$

These examples show the required assertion in the cases $d = 3, 4$ and 5.

Let $f(n) = i(Q^{(3)}_{13}, n)$, $g(n) = i(\mathcal{P}^{(4)}, n)$, $h(n) = i(\mathcal{P}^{(5)}, n)$ and

$$p(n) = i(Q^{(3)}_{12}, n) = 2n^3 + n^2 + 1.
$$

By applying Lemma 2.4 repeatedly, one sees that for each integer $s \geq 1$, the polynomial $f(n) \cdot p(n)^s$ is the Ehrhart polynomial of an integral convex polytope of dimension $3(s + 1)$. Similarly, $g(n) \cdot p(n)^s$ and $h(n) \cdot p(n)^s$ are also the Ehrhart polynomials of some integral convex polytopes of dimension $3s + 4$ and dimension $3s + 5$, respectively.
Thus, it is enough to prove that the coefficient of \( n \) of each of the polynomials \( f(n) \cdot p(n)^s \), \( g(n) \cdot p(n)^s \) and \( h(n) \cdot p(n)^s \) is negative and all the remaining coefficients are positive.

We will prove by induction on \( s \) that for each \( s \geq 0 \), the coefficient of \( n \) of \( f(n) \cdot p(n)^s \) is equal to \(-\frac{1}{6}\), the coefficient of \( n^2 \) is equal to \( s + 1 \) and all the remaining coefficients are positive. Suppose that \( s \geq 1 \) and the polynomial \( f(n) \cdot p(n)^{s-1} \) looks like

\[
f(n) \cdot p(n)^{s-1} = a_3 n^{3s} + \cdots + a_3 n^3 + sn^2 - \frac{1}{6}n + 1,
\]

where each \( a_j > 0 \). Then the direct computation shows that the coefficients of \( n, n^2, n^3 \) and \( n^4 \) of \( f(n) \cdot p(n)^s = (f(n) \cdot p(n)^{s-1}) \cdot p(n) \) are as follows:

- (the coefficient of \( n \) of \( f(n) \cdot p(n)^s \)) = \(-\frac{1}{6}\);  
- (the coefficient of \( n^2 \) of \( f(n) \cdot p(n)^s \)) = \( s + 1 \);  
- (the coefficient of \( n^3 \) of \( f(n) \cdot p(n)^s \)) = \( a_3 - \frac{1}{6} + 2 > 0 \);  
- (the coefficient of \( n^4 \) of \( f(n) \cdot p(n)^s \)) = \( a_4 + s - \frac{1}{3} > 0 \).

Moreover, since each \( a_j \) is positive, all the coefficients of \( n^r \) with \( r \geq 5 \) are also positive. Hence, the coefficient of \( n \) of \( f(n) \cdot p(n)^s \) is equal to \(-\frac{1}{6}\), the coefficient of \( n^2 \) is equal to \( s + 1 \) and all the remaining coefficients are positive. Thus, by induction on \( s \), we conclude that the Ehrhart polynomial \( f(n) \cdot p(n)^s \) satisfies the required condition for each \( s \geq 0 \). In particular, the coefficient of \( n \) of \( f(n) \cdot p(n)^s \) is negative and all its remaining coefficients are positive.

By the same discussions as above, we can conclude that the Ehrhart polynomials \( g(n) \cdot p(n)^s \) and \( h(n) \cdot p(n)^s \) also enjoy the required properties for each \( s \geq 1 \), as desired. \( \square \)

**Lemma 3.3** Given an integer \( d \geq 3 \), suppose that there is an integral convex polytope \( \mathcal{P} \) of dimension \( d \) such that the coefficient of \( n^r \) of \( i(\mathcal{P}, n) \) is negative and all its remaining coefficients are positive for some \( 1 \leq r \leq d - 2 \). Then there exists an integral convex polytope \( \mathcal{P}' \) of dimension \( d + 1 \) such that the coefficient of \( n^{r+1} \) of \( i(\mathcal{P}', n) \) is negative and all its remaining coefficients are positive.

**Proof** Let

\[
i(\mathcal{P}, n) = a_d n^d + \cdots + a_{r+1} n^{r+1} - a_r n^r + a_{r-1} n^{r-1} + \cdots + a_1 n + 1,
\]

where each \( a_j > 0 \). By applying Lemma 2.4, we see that there exists an integral convex polytope of dimension \( d + 1 \) such that \( i(\mathcal{P}', n) = (mn + 1)i(\mathcal{P}, n) \). (See also
Example 2.1.) Then
\[ i(P', n) = ma_d n^{d+1} + (ma_{d-1} + a_d) n^d + \cdots + (ma_{r+1} + a_{r+2}) n^{r+2} \]
\[ + (-ma_r + a_{r+1}) n^{r+1} + (ma_{r-1} - a_r) n^r \]
\[ + (ma_{r-2} + a_{r-1}) n^{r-1} + \cdots + (m + a_1) n + 1. \]

Hence, for a sufficiently large integer \( m \), the coefficient of \( n^{r+1} \) of the Ehrhart polynomial \( i(P', n) \) is negative and all its remaining coefficients are positive. \( \square \)

Now, we are in the position to give a proof of Theorem 1.2.

**Proof of Theorem 1.2** For a given integer \( d \geq 3 \), Lemma 3.2 directly proves the case where \( k = 1 \). Assume \( k > 1 \) and \( d > 3 \).

From \( k \leq d - 2 \), we have \( d - k + 1 \geq 3 \). Let \( \mathcal{R}^{(d-k+1)} \) be an integral convex polytope of dimension \( d - k + 1 \) such that the coefficient of \( n \) of \( i(\mathcal{R}^{(d-k+1)}, n) \) is negative and all its remaining coefficients are positive. Note that the existence of such polytope is guaranteed by Lemma 3.2. Applying Lemma 3.3 for \( \mathcal{R}^{(d-k+1)} \) \((k - 1)\) times proves the existence of an integral convex polytope \( P' \) of dimension \( d = (d - k + 1) + (k - 1) \) satisfying that the coefficient of \( n^k \) of \( i(P', n) \) is negative and all its remaining coefficients are positive, as desired. \( \square \)

### 4 A Question on Possible Sign Patterns of Coefficients

In this section, we consider the following question.

**Question 4.1** Given a positive integer \( d \geq 3 \) and integers \( i_1, \ldots, i_q \) with \( 1 \leq i_1 < \cdots < i_q \leq d - 2 \), does there exist an integral convex polytope of dimension \( d \) whose Ehrhart polynomial satisfies

- all the coefficients of \( n^{i_1}, \ldots, n^{i_q} \) are negative and
- all the remaining coefficients are positive?

We give a partial answer for Question 4.1. More precisely, we solve this in the case \( d \leq 6 \).

**Proposition 4.2** Given an integer \( 3 \leq d \leq 6 \) and integers \( i_1, \ldots, i_q \) with \( 1 \leq i_1 < \cdots < i_q \leq d - 2 \), there exists an integral convex polytope of dimension \( d \) whose Ehrhart polynomial satisfies that all the coefficients of \( n^{i_1}, \ldots, n^{i_q} \) are negative and all the remaining coefficients are positive.

**Proof** Theorem 1.2 guarantees the case \( q = 1 \) for every \( d \geq 3 \). Moreover, Theorem 1.1 guarantees the case \( q = d - 2 \) for every \( d \geq 3 \).

Thus, the remaining cases are as follows:

(a) \( d = 5, q = 2 \) and \((i_1, i_2) = (1, 2), (1, 3), (2, 3)\);
(b) \( d = 6, q = 2 \) and \((i_1, i_2) = (1, 2), (1, 3), (1, 4), (2, 3), (2, 4), (3, 4)\);
(c) \( d = 6, q = 3 \) and \((i_1, i_2, i_3) = (1, 2, 3), (1, 2, 4), (1, 3, 4), (2, 3, 4)\).
Each of these cases is guaranteed by Example 4.3 below, as required. □

**Example 4.3** (a) Let

\[ P_{1,2}^{(5)} = \text{conv} \left( \left\{ 0^5, e_1^5, e_2^5, e_3^5, e_4^5, e_5^5 + e_2^5 + 99e_4^5 + 100e_5^5 \right\} \right) \subset \mathbb{R}^5, \]

\[ P_{1,3}^{(5)} = \text{conv} \left( \left\{ 0^5, e_1^5, e_2^5, e_3^5, e_4^5, 3e_1^5 + 4e_2^5 + 5e_3^5 + 8e_4^5 + 371e_5^5 \right\} \right) \subset \mathbb{R}^5, \]

\[ P_{2,3}^{(3)} = \ell_{10} \times \ell_{10} \times Q_{100}^{(3)} \subset \mathbb{R}^5, \]

where \( \ell_{10} \) and \( Q_{100}^{(3)} \) are the polytopes appearing in Examples 2.1 and 2.2, respectively.

Then

\[ i(P_{1,2}^{(5)}, n) = \frac{5}{6} n^5 + \frac{17}{4} n^4 + \frac{29}{6} n^3 - \frac{9}{4} n^2 - \frac{8}{3} n + 1, \]

\[ i(P_{1,3}^{(5)}, n) = \frac{371}{120} n^5 + \frac{1}{8} n^4 - \frac{1}{24} n^3 + \frac{15}{8} n^2 - \frac{1}{20} n + 1, \]

\[ i(P_{2,3}^{(5)}, n) = \frac{5000}{3} n^5 + \frac{1300}{3} n^4 - 1430n^3 - \frac{577}{3} n^2 + \frac{16}{3} n + 1. \]

(b) Let

\[ P_{1,2}^{(6)} = \text{conv} \left( \left\{ 0^6, e_1^6, e_2^6, e_3^6, e_4^6, e_5^6 + e_2^6 + 999e_4^6 + 1000e_6^6 \right\} \right) \subset \mathbb{R}^6, \]

\[ P_{1,3}^{(6)} = \text{conv} \left( \left\{ e_1^3 + e_3^3 + e_4^3 + e_5^3 + 3e_1^3 + 3e_3^3 + 4e_4^3 + 4e_5^3 + e_2^3 + 3e_3^3 \right\} \right) \times Q_{26}^{(3)} \subset \mathbb{R}^6, \]

\[ P_{1,4}^{(6)} = Q_{12}^{(3)} \times Q_{16}^{(3)} \subset \mathbb{R}^6, \]

\[ P_{2,3}^{(6)} = \ell_2 \times \ell_2 \times \ell_2 \times Q_{30}^{(3)} \subset \mathbb{R}^6, \]

\[ P_{2,4}^{(6)} = \ell_{40} \times P_{1,3}^{(5)} \subset \mathbb{R}^6, \]

\[ P_{3,4}^{(6)} = \text{conv} \left( \left\{ 0^6, e_1^6, e_2^6, e_3^6, e_4^6, e_5^6 + e_2^6 + e_3^6 + 999(e_4^6 + e_5^6) + 1000e_6^6 \right\} \right) \subset \mathbb{R}^6, \]

where \( P_{1,3}^{(5)} \) is the polytope appearing in (a) above.

Then

\[ i(P_{1,2}^{(6)}, n) = \frac{25}{18} n^6 + \frac{751}{60} n^5 + \frac{2515}{72} n^4 + \frac{131}{6} n^3 - \frac{2435}{72} n^2 - \frac{617}{20} n + 1, \]

\[ i(P_{1,3}^{(6)}, n) = \frac{130}{9} n^6 + \frac{137}{6} n^5 + \frac{55}{9} n^4 - \frac{2}{3} n^3 + \frac{4}{9} n^2 - \frac{1}{6} n + 1, \]

\[ i(P_{1,4}^{(6)}, n) = \frac{16}{3} n^6 + \frac{14}{3} n^5 - \frac{1}{3} n^4 + 4n^3 + 2n^2 - \frac{2}{3} n + 1, \]

\[ i(P_{2,3}^{(6)}, n) = 40n^6 + 68n^5 + 18n^4 - 17n^3 - 5n^2 + 3n + 1, \]

\[ i(P_{2,4}^{(6)}, n) = \frac{371}{3} n^6 + \frac{971}{120} n^5 - \frac{37}{24} n^4 + \frac{1799}{24} n^3 - \frac{1}{8} n^2 + \frac{799}{20} n + 1, \]

\[ i(P_{3,4}^{(6)}, n) = \frac{25}{18} n^6 + \frac{503}{60} n^5 - \frac{241}{24} n^4 - \frac{475}{24} n^3 + \frac{281}{36} n^2 + \frac{191}{10} n + 1. \]
(c) Let

\[ P_{1,2,3}^{(6)} = \ell_1 \times \ell_1 \times \ell_1 \times Q_{40}^{(3)} \subset \mathbb{R}^6, \]
\[ P_{1,2,4}^{(6)} = Q_{10}^{(3)} \times Q_{100}^{(3)} \subset \mathbb{R}^6, \]
\[ P_{1,3,4}^{(6)} = \ell_1 \times \text{conv} \left( \{0^5, e_1^5, e_2^5, e_3^5, e_4^5, e_1^5 + 2e_2^5 + 10e_4^5 + 1000e_5^5\} \right) \subset \mathbb{R}^6, \]
\[ P_{2,3,4}^{(6)} = \ell_3 \times \ell_3 \times \ell_3 \times Q_{40}^{(3)} \subset \mathbb{R}^6. \]

Then

\[ i(P_{1,2,3}^{(6)}, n) = \frac{20}{3}n^6 + 21n^5 + \frac{55}{3}n^4 - \frac{10}{3}n^3 - 10n^2 - \frac{5}{3}n + 1, \]
\[ i(P_{1,2,4}^{(6)}, n) = \frac{250}{9}n^6 + \frac{55}{3}n^5 - \frac{161}{9}n^4 + 4n^3 - \frac{26}{9}n^2 - \frac{43}{3}n + 1, \]
\[ i(P_{1,3,4}^{(6)}, n) = \frac{25}{3}n^6 + \frac{26}{3}n^5 - \frac{11}{3}n^4 - \frac{7}{3}n^3 + \frac{1}{3}n^2 - \frac{1}{3}n + 1, \]
\[ i(P_{2,3,4}^{(6)}, n) = 180n^6 + 207n^5 - 39n^4 - \frac{250}{3}n^3 - 14n^2 + \frac{13}{3}n + 1. \]
