Running Title: MAAs stimulate the secretion of HA via HAS2

Keywords: amino acid, c-Fos, c-Jun N-terminal kinase, cell signaling, fibroblast, hyaluronan, NF-kappa B (NF-KB), p38 MAPK, protein phosphorylation, gene regulation.

ABSTRACT

Hyaluronan (HA) is an extracellular matrix glycosaminoglycan that critically supports the physicochemical and mechanical properties of the skin. Here, we demonstrate that mycosporine-like amino acids (MAAs), which typically function as UV-absorbing compounds, can stimulate HA secretion from normal human fibroblasts. MAA-stimulated HA secretion was associated with significantly increased and decreased levels of mRNAs encoding HA synthase 2 (HAS2) and HA-binding protein involved in HA depolymerization (HYBID), respectively. Using immunoblotting, we found that MAAs at 10 μg/ml and at 25 μg/ml stimulate the phosphorylation of the mitogen-activated protein kinase (MAPK) p38, extracellular signal–regulated kinase (ERK)/c-Jun, mitogen- and stress-activated protein kinase 1 (MSK1) (at Thr-581, Ser-360, and Ser-376, respectively) and activation of cAMP-responsive element–binding protein (CREB) and activating transcription factor 2 (ATF2), but not phosphorylation of JUN N-terminal kinase (JNK) or NFkB (at Ser-276 or Ser-536, respectively), and increased c-Fos protein levels. Moreover, a p38-specific inhibitor, but not inhibitors of MAPK/ERK kinase (MEK), JNK, or NFkB, significantly abrogated the increased expression of HAS2 mRNA, accompanied by significantly decreased MAA-stimulated HA secretion. These results suggested that the p38–MSK1–CREB–c-Fos–transcription factor AP-1 (AP-1) or the p38–ATF2 signaling cascade is responsible for the MAA-induced stimulation of HAS2 gene expression. Of note, siRNA-mediated ATF2 silencing failed to abrogate MAA-stimulated HAS2 expression, and c-Fos silencing abolished the increased expression of HAS2 mRNA. Our findings suggest that MAAs stimulate HA secretion by up-regulating HAS2 mRNA levels through activation of an intracellular signaling cascade consisting of p38, MSK1, CREB, c-Fos, and AP-1.

Hyaluronan (HA) is an important component of the extracellular microenvironment that supports the typical physicochemical and mechanical properties of the skin. Thus, HA has important structural functions via mechanisms by which its high polymer length and polyanionic charge enable it to bind water, which in turn supports volume expansion, turgidity and skin elasticity (1). In photodamaged skin, there is a marked deficiency of HA in the dermis (2, 3), in addition to the fragmentation and loss of type I collagen fibrils due to the up-regulated
activity of matrix-metalloprotease (MMP)-1 (4, 5). Further, the three-dimensional configuration of elastic fibers is impaired due to the up-regulated expression of fibroblast-derived elastase neprilysin (6-13). The sum of those effects is associated with the decreased elasticity of the skin as well as the subsequently increased incidence of skin wrinkles and sagging. That association is consistent with our earlier studies, which demonstrated that a significant reduction of cutaneous elastic properties is a prerequisite factor for the initiation of skin wrinkle formation and that there is a close relationship of impaired skin elasticity with both the clinical scores and the depth of wrinkles as revealed by morphometric analysis (14, 15). Consistently, in clinical studies of human skin, the formation or the amelioration of facial wrinkles is distinctly accompanied by a marked loss or recovery of skin elastic properties, respectively (14-16). In support of the relationship between HA content in the dermis and cutaneous photoaging symptoms, Yoshida et al. (17, 18) recently demonstrated that there is a marked loss of HA in the papillary dermis of photoaged facial skin, the diminished level of which is associated with the degree of skin wrinkling and sagging in the same aged skin. Their studies strongly suggested that a deficiency of HA in photoaged skin contributes to the formation of skin wrinkles and sagging.

HA is a linear polymer composed of repeating disaccharides (D-glucuronic acid; 1,3-N-acetylg glucosamine; 1,4-N-acetylglucosamine) that is assembled from activated nucleotide sugars (UDP-glucuronic acid and UDP-N-acetylglucosamine) at the inner plasma membrane by HA synthases (HAS). Three different isoforms of HAS (HAS1, HAS2 and HAS3) are known to reside in the plasma membrane and to extrude the growing HA polymer into the extracellular space (19). Two different isoforms of hyaluronidase (HYAL) (HYAL1 and HYAL2) are known to cleave HA into discrete fragments (20), which in turn activate Toll-like receptors 2 and 4 and thereby modulate inflammatory responses (21, 22). A third isoform of HYAL (HYAL3) is expressed, although its properties are not well understood. Nevertheless, Yoshida et al. recently ruled out the possible roles of HYALs in the degradation of HA by human fibroblasts and indicated that KIAA1199, a novel HA binding protein recently designated as “HYBID” (HYaluronan Binding protein Involved in HA Depolymerization), plays a key role in the degradation of HA by fibroblasts in normal human skin (23). Thus, it has become clear that the balance of HAS and HYBID functions as a key factor in regulating HA content in the dermis.

We considered that if percutaneously permeable natural compounds with small molecular weights exist that have the potential to stimulate the secretion of HA by human fibroblasts, they would be good candidates for ameliorating or preventing the loss of skin elastic properties as prerequisite factors of wrinkles and sagging formation in photoaged skin. Under this expectation, in a screening for natural compounds that could stimulate the secretion of HA by human fibroblasts, we now report for the first time that mycosporine-like amino acids (MAAs) have a significant potential to stimulate the secretion of HA by normal human fibroblasts without any cytotoxic effect on cellular viability.

MAAs are generally defined as amino acids with cyclohexanone or cyclohexeniminine in their basic structure. MAAs are present as small secondary metabolites in different organisms such as aquatic yeasts (24), cyanobacteria (25), marine dinoflagellates (26) and some Antarctic diatoms (27), all of which live in environments with high exposure to sunlight, usually marine environments. The number of compounds within this class of natural products has been discovered, to date, to be around 30 (28, 29). Since the basic cyclohexanone or cyclohexeniminine structures act as chromophores responsible for UV absorbance, MAAs are well known as UV-absorbing compounds, their filter capacities being similar to synthetic UVA sunscreens such as Parsol® 1789 (emolar 40000) and Mexoryl® SX (emolar 45000) (30). MAAs have also recently been shown to act as antioxidants.
(31) by increasing the ratio of reduced (GSH) to oxidized glutathione (GSSG) in UV-exposed cells (32) and as anti-apoptotic agents by abrogating UV-induced increases in active caspase-3 protein (33). However, there have been no reports showing the stimulatory effect of MAAs on HA secretion by any kind of mammalian cell in culture.

In the present study, using human dermal fibroblasts (HDFs), we characterized the stimulatory effect of MAAs in terms of its biological mechanism as well as the signaling mechanisms involved in the stimulation. Here we show for the first time that MAAs have a significant potential to stimulate HA secretion by up-regulating HAS2 mRNA levels in HDFs, which results from activation of the intercellular signaling cascade consisting of the p38/MSK1/CREB/c-Fos/AP-1 axis.

Results and Discussion

Purification of MAAs and HPLC/LC-MASS analysis

MAAs were extracted and purified as detailed in the Supplementary Materials and Methods and were identified as porphyra-334 and shinorine (Fig. 1) by HPLC/LC-MASS analysis as described in Supplementary Results. The contents of porphyra-334 and shinorine in MAAs used in this study were calculated as 88.8% and 11.2%, respectively.

Effects of MAAs on the functional properties of HDFs

When HDFs were cultured for 72 h in the presence or absence of MAAs at 1, 10 or 25 μg/mL to HDFs in culture, the secretion levels of HA in the medium increased significantly in the presence of 10 or 25 μg/ml MAAs compared with untreated control HDFs (Fig. 2A).

To determine whether MAAs are cytotoxic to HDFs, we cultured HDFs for 72 h in the absence or presence of MAAs at 10 and 25 μg/mL and their viability was evaluated by cellular morphology and by the MTT assay. The results showed that there were no morphological changes in HDFs treated with 10 or 25 μg/mL MAAs (data not shown) and there was actually a significant increase in cell viability of HDFs treated with 10 and 25 μg/mL MAAs compared to untreated controls (Fig. 2B).

To determine the effects of MAAs on the functional properties of HDFs, i.e. DNA synthesis and production of collagen I and elastin, we cultured HDFs for 72 h in the absence or presence of 10 or 25 μg/mL MAAs. The results showed that MAAs did not stimulate DNA synthesis, or expression levels of collagen I and elastin mRNAs at 10 or 25 μg/mL (Fig. 2C, 2D, 2E).

The sum of those findings indicates that MAAs stimulate the secretion of HA by HDFs without any cytotoxic effect on cell viability and that stimulatory effect is not accompanied by increased levels of other cellular functions of fibroblasts such as the synthesis of collagen I, elastin and DNA.

Effects of MAAs on HAS and HYBID mRNA levels in HDFs

Since the secretion of HA by HDFs is regulated by HAS1, HAS2 and HAS3 and by the HA degradative protein HYBID (23), we then determined the effects of MAAs on the gene expression levels of HAS1, HAS2 and HAS3 and on the gene and protein expression levels of HYBID. When HDFs were treated with MAAs at 25 μg/mL, the gene expression levels of HAS2 (Fig. 3A) and HYBID (Fig. 3C) were significantly increased or decreased, respectively, at 3–12 h post-treatment, but there was no change in the HAS3 mRNA level (Fig. 3B); the level of HAS1 mRNA was undetectable (data not shown). Analysis of the effects of MAAs on mRNA levels of HAS2 revealed that MAAs significantly up-regulated the gene expression level of HAS2 in a dose-dependent fashion at concentrations of 25-50 μg/mL (Fig. 3D). Western blotting using an anti-HYBID antibody revealed that MAAs at 1, 10 and 25 μg/mL did not affect the level of HYBID protein at 6 or 24 h post-treatment (Fig. 3E).

HAS2 enzyme produces HA with a high-molecular-weight (1,000-10,000 kDa) (34) whereas HYBID is associated with the depolymerization of HA from a high-molecular weight to >35 kDa (23). Since the
ELISA assay used in this study detects only HA with >35 kDa (35) and since the expression of HYBID protein is not affected by the treatment with MAAs, the MAA-induced increase in the secretion of HA is predominantly attributable to the increased synthesis of HA, which results from the increased expression of HAS2.

To test that possibility, we determined the effects of transfecting a HAS2 siRNA on the MAAs-increased secretion of HA. The results indicated that the HAS2 siRNA significantly abolished the secretion of HA both in MAAs-treated and non-treated fibroblasts (Fig. 4). Since the up-regulated gene expression level of HAS2 is mainly responsible for the increased secretion of HA elicited by treatment with MAAs, we next characterized what intracellular signaling cascades are activated by MAAs that result in the up-regulated gene expression level of HAS2.

**Effects of MAAs on intracellular signaling cascades in HDFs**

It has been reported that HA secretion and synthesis is up-regulated in concert with the increased gene expression level of HAS2 by several chemicals or stimuli via different signaling pathways depending on the cell species and chemicals used. 20-O-β-D-glucopyranosyl-20(S)-protopanaxadiol enhances the expression of HAS2 in human keratinocytes via the activation of ERK and Akt signaling, which is mediated by Src but not the JNK, p38, EGFR or the Ca²⁺-related signaling pathways (36). The stimulation of HAS2 expression by transforming growth factor (TGF)-β1 in human skin fibroblasts is abrogated by blocking MAPK and/or Smad signaling and PI3K-Akt signaling (37). All-trans retinoic acid stimulates HA synthesis in normal human tracheobronchial epithelial cells by activating CREB1 in a non-classical, retinoic acid receptor-independent fashion via the protein kinase C or the ERK/RSK/CREB cascade (38). UTP specifically up-regulates HAS2 expression among the three HAS genes through the UTP receptor P2Y2, which is accompanied by the increased phosphorylation of p38, ERK, CREB and STAT3 and by the induced nuclear translocation of pCaMKII, whose inhibitors (for PKC/p38/ERK/CaMKII/STAT3/CREB) partially block the stimulation of HAS2 expression (39). The UDP-glucose-induced up-regulation of HAS2 mRNA levels in human immortalized epidermal keratinocytes is mediated via the JAK2/ERK/STAT3 signaling pathway (40). A neutral sphingomyelinase inhibitor or its deficiency in mouse fibroblast cell lines stimulates HAS2 gene expression via the Akt/mTOR pathway (41). Low dose UVB exposure of rat keratinocytes enhances HA secretion accompanied by the increased expression level of HAS2 mRNA, which is mediated by p38 signaling (42). In contrast, methyl-beta-cyclodextrin suppresses HA synthesis by down-regulating HAS2 through the inhibition of Akt (43). On the other hand, transcription factors that primarily target the HAS2 gene are known to include RAR (44), STAT3, SP1 (45, 46), NF-kB (47) and CREB (48) in a variety of cells.

Thus, we first examined the potential effects of MAAs on p38 signaling. Western blot analysis of p38 phosphorylation revealed that MAAs at 25 µg/mL significantly activate p38 in HDFs at 15 and 30 min post-stimulation (Fig. 5A), which suggests that MAAs-activated signaling occurs in a similar fashion to UVB-activated signaling (42). In UVB-exposed human or rat keratinocytes (44, 49, 50) or human melanocytes (51), the activation of the front line of stress-activated signaling factors occurs at p38, JNK and ERK by which their downstream signaling factors such as MSK1 for p38 and ERK (52, 53), MAPK-APK2 for p38 (54), CK2/i-kB/NFkB for p38 (55) and ATF2 for p38 (56) as well as c-Jun and c-Fos for ERK (57, 58) are subjected to subsequent and sequential signaling activation. During these downstream cascades, further signaling factors such as CREB for MSK1 (59), NFkB (Ser276) for MSK1 (60, 61) and c-Fos for CREB (62) are continuously and sequentially activated. Several functional proteins that are highly expressed in UVB-exposed human keratinocytes or human melanocytes, such as
cyclooxygenase (COX)2 (50), interleukin (IL)-8 (50), transglutaminase1 (49) (in human keratinocytes), endothelin B receptor (51, 63) and stem cell factor receptor c-KIT (in human melanocytes) (63, 64) utilize their characteristic and specific signaling cascades to elicit their increased gene expression.

Therefore, based on the known UVB-activated intracellular signaling pathway (49, 51), we characterized the activating or non-activating effects of MAAs on the front line of stress-activated signaling, JNK and ERK other than p38. Western blot analysis of the phosphorylation of ERK (Fig. 5B) and JNK (Fig. 5C) revealed that MAAs at 10 and/or 25 μg/mL have a significant potential to activate ERK but not JNK at 15 or 30 min post-treatment in HDFs. We next characterized the activating or non-activating effects of MAAs on downstream signaling factors, MSK1 (Thr581/Ser360) for p38 and ERK, and ATF2 for p38. Western blot analysis of the phosphorylation patterns demonstrated that MAAs at 10 and/or 25 μg/mL have a significant potential to activate ATF2 (Fig. 5D) and MSK1 (Thr581/Ser360/Ser376, the latter of which is an autophosphorylation site after MSK1 phosphorylation at Thr581/Ser360) (Fig. 5E, 5F, 5G) at 15 or 30 min post-treatment. As for the activating or non-activating effects of MAAs on downstream signaling factors, c-Jun for ERK, NFkB(Ser276) for MSK1, NFkB(Ser536) for ERK/IKK and IκB (Ser32/36) for CK2 or IKK, Western blot analysis of the phosphorylation patterns demonstrated that MAAs at 10 and 25 μg/mL do not have any potential to activate c-Jun (Fig. 5H) or NFkB(Ser276/Ser536) (Fig. 5I, 5J) at 15 and 30 min post-treatment in HDFs. Similarly, the phosphorylation of IκB(Ser32/36) was not stimulated by MAAs at 10 or 25 μg/mL in contrast to their stimulated phosphorylation by IL-1α (Fig. 5K) in which IκB protein used as a loading control became undetectable probably due to a rapid degradation of phosphorylated IκB.

Finally, we examined the activating or non-activating effects of MAAs on downstream signaling factors, CREB for MSK1 and c-Fos for CREB. Western blot analysis of the phosphorylation patterns and protein levels demonstrated that MAAs at 10 and/or 25 μg/mL have a significant potential to stimulate CREB phosphorylation (Fig. 5L) and to increase c-Fos protein levels at 15 and 30 min and 2 h post-treatment, respectively, in HDFs (Fig. 5M).

Thus, our intracellular signaling analysis for the phosphorylation and protein levels of various signaling factors revealed that MAAs at 10 and/or 25 μg/mL initiate the activation at the front line of stress-activated signaling cascade, including ERK and p38, which contribute sequentially to the activation of MSK1(Thr581/Ser360/Ser376) via their downstream lineages. The activation of MSK1 results predominantly in the activation of CREB but not of NF-kB(Ser276) in the MAAs-activated signaling cascades. These findings indicate that the downstream lineage of MSK1 exists as a convergent point distinct from UVB-activated ones. Thus, it is interesting to note that whereas activated MSK1 elicits the increased phosphorylation of both CREB and NF-kB(Ser276) in the UVB-activated signaling cascades (49), the stimulated phosphorylation of NFkB at Ser276 does not occur downstream of activated MSK1 in the MAAs-activated signaling cascades. The phosphorylation of NF-kB at Ser536 and IκBα at Ser32/36, which simultaneously occurs downstream of IKK/Akt (49, 65), is known to be essentially involved in the disassociation of the complex consisting of IκBα and NF-kB, resulting in its subsequent degradation and translocation from the cytosol to the nucleus, respectively (65). Since the phosphorylation of NF-kB at Ser536 and IκB at Ser32/36 was not stimulated in MAAs-treated HDFs and since MSK1 is known as a nuclear kinase, functioning only within nuclei (60), it is conceivable that the failure to activate the downstream lineage of MSK1 for NF-kB(Ser276) in the MAAs-activated signaling pathway is due to the lack of IκBα phosphorylation and the subsequent translocation of NFkB from the cytosol to the nucleus. On the other hand, since induction of the c-Fos promoter is known to be mediated...
by CREB binding to CRE and c-Fos activator protein in UVB-exposed mammalian cells (62), it is likely that the increased protein level of c-Fos in MAAs-treated HDFs is directly linked to the activation of CREB, which results directly from the activation of MSK1. The sum of the above findings indicates that treatment of HDFs with MAAs at 25 μg/mL significantly stimulates the signaling cascades of p38/MSK1/CREB/c-Fos and p38/ATF2, whereas it does not activate the ERK/c-Jun, IKK/IκB/NF-κB or MSK1/NF-κB signaling cascades.

**Effects of p38, JNK and MEK inhibitors on MAAs-increased gene expression of HAS2 and the stimulated secretion of HA in HDFs**

Further studies to identify the activated signaling cascades specific for the increased gene expression level of HAS2 revealed that a p38 inhibitor (SB239063) significantly abrogated the MAAs-elicted increase in HAS2 mRNA level in concert with an abrogating effect on the enhanced secretion of HA (Fig. 6A, 6B). In contrast, inhibitors of JNK (Inhibitor II) and NFκB (JSH23) did not abolish the MAAs-elicted increase in HAS2 mRNA level (Fig. 6C), which is consistent with the lack of any substantial activation of the JNK or NFκB linkages observed in the MAAs-activated signaling pathway. On the other hand, a MEK inhibitor (U0126) did not abrogate the MAAs-elicted increase in HAS2 mRNA level (Fig. 6D), which strongly suggests there is no involvement of the ERK/c-Jun axis in the MAAs-activated signaling cascade specifically attributable to the MAAs-stimulated expression level of HAS mRNA, which is consistent with non-stimulated phosphorylation of c-Jun. Thus, the above detailed analysis of signaling pathways that lead to the stimulated expression level of HAS2 mRNA suggests the possible refinement that the MAAs-stimulated expression level of HAS2 mRNA is mediated via either the p38/MSK1/CREB/c-Fos/AP-1 axis or the p38/ATF2 axis.

**Effects of transfecting an ATF2 siRNA or a c-Fos siRNA on the MAAs-increased gene expression of HAS2 in HDFs**

Although there has been no evidence indicating the involvement of AP-1 or ATF2 as transcription factors regulating HAS2 gene expression, we attempted to use mRNA silencing to identify the terminal point of the intracellular signaling pathway leading to the transcriptional process that increases levels of HAS2 mRNA. In elucidating which transcription factor, AP-1 or ATF2, might be essentially involved in the MAAs-stimulated expression level of HAS2 mRNA, although transfection of ATF2 siRNA significantly reduced the level of ATF2 protein and abrogated the MAAs-increased phosphorylation level of ATF2 (Fig. 7A), the ATF2 siRNA failed to abrogate the stimulated expression level of HAS2 mRNA by MAAs (Fig. 7C). On the other hand, while the transfection of a c-Fos siRNA significantly reduced the level of c-Fos protein and abrogated the MAAs-increased level of c-Fos protein (Fig. 7B), the c-Fos siRNA significantly abolished the increased expression level of HAS2 mRNA by MAAs (Fig. 7C).

**Conclusion**

As summarized schematically in Figure 8, the sum of these findings strongly suggests that MAAs up-regulate the gene expression level of HAS2 via an activation of the intracellular signaling cascade consisting of the p38/MSK1/CREB/c-Fos/AP-1 axis that stimulates the production and secretion of HA by HDFs.

**Experimental procedures**

**Materials**

Antibodies to ERK, phosho-ERK, p38, phosho-p38, JNK, phosho-JNK, p-IκB, phosho-IκB, NFκBp65, phoshoSer276/Ser536NFκBp65, CREB, phoshoSer133CREB, c-Fos, ATF2, phoshoThr71ATF2, MSK1 and phosho-Thr581/Ser376/Ser360MSK1 were purchased from Cell Signaling Technology (Danvers, MA, USA). Antibodies to β-actin and HYBID (Anti-KIAA1199) were obtained from Sigma-Aldrich Corp., St. Louis, MO, USA). antibody
produced in rabbit

The NFκB activation inhibitor II (JSH-23) and the MEK inhibitor (U0126) were from Calbiochem (San Diego, CA, USA), the p38 inhibitor (SB239063) was from Santa Cruz Biotechnology, Inc. (Heidelberg, Germany) and the JNK inhibitor (JNK inhibitor II) was from Merck KGaA (Darmstadt, Germany).

**Cell cultures**
HDFs derived from human foreskins (Thermo Fisher Scientific, Waltham, MA, USA) were cultivated in Dulbecco’s modified Eagle’s medium (DMEM) with 10% fetal bovine serum (FBS) at 37℃ in a 95% air, 5% CO₂ atmosphere.

**Cell viability assay**
Cell viability assays were performed using a Cell Proliferation kit I (MTT assay) (Roche Diagnostics Corp, Indianapolis, IN, USA) according to the manufacturer’s instructions. HDFs were cultured for 72 h in the presence of MAAs and their viability was evaluated using the MTT assay.

**DNA synthesis**
DNA synthesis was measured using a CytoSelect™ BrdU Cell Proliferation ELISA kit (Cell Biolabs, Inc., San Diego, CA, USA).

**Measurement of HA**
HDFs were seeded in DMEM with FBS and were cultured for 12 h. After exchange with fresh DMEM without FBS, HA secreted into the culture medium was measured at the indicated times of culture using an HA assay kit (R&D Systems, Inc., Minneapolis, MN, USA), which can detect HA with molecular weight ≥35 kDa according to the instructions of the manufacturer. Levels of HA are expressed as ng/mL.

**Real time qRT-PCR**
After exchange with fresh DMEM without FBS, levels of mRNAs encoding HAS1, HAS2, HAS3, HYBID, collagen I and elastin in HDFs were measured at the indicated times of culture using real-time qRT-PCR. Total RNA was isolated from HDFs using a ReliaPrep™ RNA Miniprep System (Promega Corp, Madison, WI, USA), followed by reverse transcription to cDNA using ReverTra Ace® qPCR RT Master Mix (Toyobo Co. Ltd., Osaka, Japan). Real time PCR reactions were analyzed using SYBR Fast qPCR Mix (Takara Bio, Otsu, Shiga, Japan) and a Light Cycler 96 (Roche). The respective primers are shown in Table 1. The mRNA expression level was corrected by the expression level of GAPDH or Ribosomal Protein Lateral Stalk Subunit P0 (RPLP0).

**siRNA Transfection**
HDFs were plated at 6.0×10⁴ in wells of 12-well plates and were cultured for 1 day in DMEM with 5% FBS. On day 1, HDFs were transfected with a control siRNA (MISSION® siRNA Universal Negative Control, Sigma Aldrich, St. Louis, MO, USA), an ATF2 siRNA or a c-Fos siRNA (Mission siRNA, Sigma–Aldrich) and an HAS2 siRNA using Lipofectamine RNAiMAX Transfection Reagent (Invitrogen, Carlsbad, CA, USA) following the manufacturer’s protocol.

**Western Blotting**
After exchange with fresh DMEM without FBS, HDFs were cultured for the indicated times and were then solubilized in lysis buffer (50 mM Tris, pH 7.6, 150 mM NaCl and 1% Triton X-100) plus protease inhibitors (Complete mini-tablets; Boehringer Mannheim, Mannheim, Germany) and were then centrifuged at 13,000 rpm for 15 min. The supernatants were harvested and lysed in 2× loading buffer (125 mM Tris, pH 6.8, 4.6% sodium dodecyl sulfate (SDS), 20% glycerol and 0.04% pyronin Y). The mixture was then boiled for 5 min. Samples were solubilized in SDS sample buffer plus 50 mM dithiothreitol and boiled for 5 min. Total proteins from cultures of HDFs were subjected to Western blotting with antibodies to various phosphorylated or non-phosphorylated signaling factors and to β-actin as a loading control. Samples were separated on SDS-PAGE gels, transferred onto nitrocellulose membranes, blocked with 5% nonfat dry milk.
in Tris-buffered saline (TBST) and probed with the above antibodies at room temperature for 1 h. Membranes were washed 3 times for 15 min each with TBST, probed with peroxidase-conjugated secondary antibodies (GE Healthcare Bioscience, Piscataway, NJ, USA), then washed three times for 30 min each in TBST and developed by ECL (GE Healthcare Bioscience). Detection was performed using an imaging system (WSE-6100 LuminoGraph I; ATTO Corp., Tokyo, Japan).

Statistics
All data are expressed as means ± SD as indicated in the Figure Legends. Student’s t-test was applied for pairwise comparisons. For multiple comparisons, data were tested by one-way ANOVA and were subsequently analyzed using the Tukey multiple comparison test. P values < 0.05 are considered statistically significant.

Data Availability Statement: All data are contained within the manuscript

Acknowledgements: We sincerely acknowledge Dr. Vince Hearing for his critical reading.

Conflict of Interest: The authors have declared that no conflict of interest exists.

Author Contributions: AY and GI designed this research study. ST and MN conducted cellular and analytical experiments, respectively. AY supplied reagents used. ST, MN and GI analyzed data and wrote this manuscript.

| **RPLPO**   | Forward 5'-TTCGACAATGCGACATCT-3'  
Reverse 5'-CTACAGACACACTGGCAACA-3' |
MAAs stimulate the secretion of HA via HAS2

Figures and Figure Legends

**Figure 1.** Chemical structures of porphyra-334 and shinorine.

**Figure 2.** A: Effects of MAAs on the secretion level of HA by HDFs in culture. MAAs at 0, 1, 10 or 25 μg/mL were added to cultures of HDFs for 72 h as noted and the conditioned medium was measured for HA levels by ELISA assay. Data represent means ± SD. n=4, **: p<0.01 vs control (0 μg/mL). B: Effects of MAAs on the viability of HDFs in culture. HDFs were cultured for 72 h in the presence of MAAs at the indicated concentrations and their viability was evaluated using the MTT assay. **: p<0.01 vs control (0 μg/ml). Data represent means ± SD. n=4. C/D/E: Effects of MAAs on DNA synthesis (C) and collagen 1 (D) and elastin (E) mRNA levels in HDFs. DNA synthesis was measured 48 h after incubation with MAAs at the indicated concentrations using a cell proliferation ELISA kit. Collagen and elastin mRNA levels were measured by qRT-PCR 3 h after incubation with MAAs at the indicated concentrations. Data represent means ± SD. n=4
MAAs stimulate the secretion of HA via HAS2

Figure 3. Effects of MAAs on levels of HAS2 mRNA (A/D), HAS3 mRNA (B), HYBID mRNA (C) and protein (E) in HDFs. HDFs were cultured in the presence or absence of MAAs at 25 μg/mL (A/B/C) or at 0–50 μg/mL (D/E) for the indicated times (A/B/C) or 3 hr (D) and were then subjected to qRT-PCR analysis for HAS2, HAS3 and HYBID mRNA levels or to western blotting for HYBID protein levels. Representative immunoblots from three independent experiments are shown (E). Data represent means ± SD, A: n=3, B: n=6, C: n=5, D: n=4, E: n=3, *: p<0.05, **: p<0.01 vs the non-treated control (0 μg/mL).
MAAs stimulate the secretion of HA via HAS2

Figure 4. Effects of transfecting a HAS2 siRNA on the MAA-increased secretion of HA in HDFs. 
A: Effects on HAS2 mRNA levels, B: Effects on HA secretion levels. After transfection of HAS2 siRNA, HDFs were cultured in the presence or absence of MAAs at 25 μg/mL for 72 h and then were subjected to qRT-PCR analysis for mRNA levels of HAS2. The conditioned medium was measured at 72 h post-treatment for HA levels by ELISA assay. Data represent means ± SD. n=4, *: p<0.05, **: p<0.01 vs control (0 μg/mL) or negative siRNA.

Figure 5. Effects of MAAs on intracellular signaling cascades of p38 (A), ERK (B), JNK (C), ATF2 (D), MSK1 (Thr581/Ser360/Ser376) (E/F/G), c-Jun (H), NFκB (Ser276/Ser536) (I/J), IκB (K), CREB (L) and c-Fos (M) in HDFs. HDFs were incubated with MAAs or with IL-1α at the indicated concentrations and were harvested at 15 and 30 min or 2 hr post-treatment and then immunoblotted with antibodies to β-actin and to phosphorylated or non-phosphorylated signaling factors. K: β-actin was used as a loading control because of undetectable level of non-phosphorylated IκB protein in IL-1α-treated cells. Representative immunoblots from three independent experiments are shown. Data represent means ± SD., n=3, *: p<0.05, **: p<0.01 vs control (0 μg/mL)

Figure 6. Effects of p38, JNK, NFkB and MEK inhibitors on the MAAs-increased gene expression of HAS2 and MAA-stimulated secretion of HA in HDFs. HDFs were incubated with MAAs at 25 μg/mL in the presence or absence of signaling inhibitors for 3, 6 or 72 h and cell lysates or the conditioned medium were subjected to RT-PCR analysis or ELISA, respectively. A: p38 inhibitor/qRT-PCR, 6 h, data represent means ± SD, n=4, *: p<0.05, **: p<0.01, vs MAAs (0 or 25 μg/mL) B: p38 inhibitor/ELISA, 72 h, data represent means ± SD, n=4, **: p<0.01 vs MAAs (0 or 25 μg/mL) C: NFkB and JNK inhibitors/qRT-PCR, 6 h, data represent means ± SD, n=5, *: p<0.05, **: p<0.01 D: MEK inhibitor/qRT-PCR, 3 h, data represent means ± SD, n=4, *: p<0.05, **: p<0.01 vs MAAs 0 μg/mL or MEK inhibitor 0 μM.
**Figure 7.** Effects of transfecting an ATF2 siRNA or a c-Fos siRNA. **A:** Effect of transfecting an ATF2 siRNA on the expression of ATF2 protein and its phosphorylation. HDFs were incubated with or without MAAs at 25 μg/mL. Lysates were harvested at 15 min post-treatment and were
immunoblotted with antibodies to β-actin and to phosphorylated or non-phosphorylated ATF2. Representative immunoblots from three independent experiments are shown. Data represent means ± SD, n=3, **: p<0.01. B: Effect of transfection of a c-Fos siRNA on the MAAs-stimulated expression of c-Fos protein. HDFs were incubated with or without MAAs at 25 μg/mL. Lysates were harvested at 2 h post-treatment and were immunoblotted with antibodies to β-actin and c-Fos. Representative immunoblots from three independent experiments are shown. Data represent means ± SD, n=3, *: p<0.05, **: p<0.01. C: Effects of transfection of an ATF2 siRNA or a c-Fos siRNA on MAAs-increased gene expression of HAS2 in HDFs. After transfection of an ATF2 siRNA or a c-Fos siRNA, HDFs were cultured in the presence or absence of MAAs at 25 μg/mL for 3 h and then were subjected to RT-PCR analysis for mRNA levels of HAS2. Data represent means ± SD, n=3, *: p<0.05, **: p<0.01.

Figure 8. MAAs-activated signaling cascades leading to the increased secretion of HA.
Mycosporine-like amino acids stimulate hyaluronan secretion by up-regulating hyaluronan synthase 2 via activation of the p38/MSK1/CREB/cFos/AP-1 axis
Shuko Terazawa, Masahiko Nakano, Akio Yamamoto and Genji Imokawa
