C-C chemokine receptor type 2 (CCR2) is expressed on monocytes and facilitates their recruitment to tumors. Though breast cancer cells also express CCR2, its functions in these cells are unclear. We found that Ccr2 deletion in cancer cells led to reduced tumor growth and approximately twofold longer survival in an orthotopic, isograft breast cancer mouse model. Deletion of Ccr2 in cancer cells resulted in multiple alterations associated with better immune control: increased infiltration and activation of cytotoxic T lymphocytes (CTLs) and CD103+ cross-presenting dendritic cells (DCs), as well as up-regulation of MHC class I and down-regulation of checkpoint regulator PD-L1 on the cancer cells. Pharmacological or genetic targeting of CCR2 increased cancer cell sensitivity to CTLs and enabled the cancer cells to induce DC maturation toward the CD103+ subtype. Consistently, Ccr2−/− cancer cells did not induce immune suppression in Batf3−/− mice lacking CD103+ DCs. Our results establish that CCR2 signaling in cancer cells can orchestrate suppression of the immune response.

Introduction

Tumors escape immune control via multiple mechanisms (Dunn et al., 2002, 2004). These mechanisms include cancer cell-intrinsic changes that alter how the cancer cell is recognized by the immune system and extrinsic changes that suppress immune cell activities. For example, cancer cells can intrinsically decrease the surface expression of MHC class I, making them effectively invisible to cytotoxic T lymphocytes (CTLs; Garrido et al., 2016). Moreover, cancer cells can up-regulate programmed cell death ligand 1 (PD-L1/B7-H1), which binds the PD-1 receptor on activated T cells, resulting in T cell anergy, ultimately protecting cancer cells against T cell–mediated killing (Chen et al., 2016a). Extrinsic mechanisms include the down-regulation of costimulatory molecules (e.g., CD86) on antigen-presenting cells; the secretion of cytokines that directly inhibit CTLs; and the recruitment of regulatory T cells and myeloid-derived suppressor cells (MDSCs; Igney and Krammer, 2002). In contrast, infiltration of CD103+ dendritic cells (DCs) in mice, phenotypically similar to CD141+ DCs in humans (Hildner et al., 2008), has emerged as a mechanism by which tumors may be kept under immune control. CD103+ DCs are highly efficient at acquiring and processing exogenous antigens, which they directly present on MHC class I molecules to CD8+ CTLs. Even a modest accumulation of CD103+ DCs in tumors has been associated with improved immune-mediated tumor control (Broz et al., 2014; Roberts et al., 2016).

Chemokine receptors mediate the recruitment of immune cells to sites of inflammation and to tumors. C-C chemokine receptor type 2 (CCR2) is expressed by several bone marrow–derived cell types (including inflammatory monocytes, myeloid precursor cells, and immature DCs), as well as B and T lymphocytes (Lim et al., 2016). CCR2-expressing cells are recruited to sites of inflammation primarily by C-C chemokine ligand 2 (CCL2; Deshmule et al., 2009), although other CCL family members also can activate CCR2. Chemotherapy treatment promotes CCR2-dependent infiltration of tumor-promoting myeloid cells to murine mammary tumors (Nakasone et al., 2012), and CCL2/CCR2–mediated recruitment of CCR2+ inflammatory monocytes to the lung has been shown to promote breast cancer extravasation and metastasis in mouse models (Qian et al., 2011). Furthermore, elevated levels of CCL2 in tumors and in serum are associated with advanced disease and poor prognosis in breast carcinoma patients (Lebrecht et al., 2004, 2001; Sorti and Ben-Baruch, 2008). These findings have sparked interest in targeting the CCR2 pathway to modulate the innate immune response for
therapeutic benefit in cancer. However, CCR2 is also expressed by breast cancer cells, and activation of CCR2 by CCL2 can induce cancer cell migration and survival through Smad3-, p42/44MAPK-, and Rho guanosine triphosphatase–mediated signaling (Fang et al., 2012). In vivo, the potential roles of CCR2 signaling in cancer cells have not been well investigated, largely because they were thought to be minor compared with the roles of CCR2 in myeloid cells.

In this study, we report that CCR2 signaling in cancer cells plays a surprisingly major role in regulating the immune response to murine breast tumors. We show that CCR2 in cancer cells supports immune escape by inhibiting CD103+ DC infiltration and maturation and by suppressing CTL activity. CCR2 expression on cancer cells represents a previously uncharacterized mechanism for immune suppression. Thus, our data support the notion that the CCL2/CCR2 axis is an important immune mechanism for immune suppression.

**Results**

**CCR2 in cancer cells promotes primary tumor growth in an orthotopic, isograft breast cancer mouse model**

To investigate the potential effects of CCR2 on breast tumor growth and metastasis, we crossed Ccr2+/− mice (Boring et al., 1997) with mouse mammary tumor virus–polyoma middle T (MMTV-PyMT) mice, a model of luminal B breast cancer (Guy et al., 1992; Lin et al., 2003). The Ccr2 genotype did not influence normal mammary gland development (Fig. S1 A) or tumor onset (Fig. 1 A); however, loss of even one allele of Ccr2 significantly reduced tumor growth rates (Fig. 1 B). Consistently, survival time was significantly longer for the MMTV-PyMT;Ccr2+/− and MMTV-PyMT;Ccr2−/− mice compared with that of the MMTV-PyMT;Ccr2+/− mice (Fig. 1 C). In addition, we noted that the tumors of MMTV-PyMT;Ccr2−/− and MMTV-PyMT;Ccr2+/− mice were more cystic, with reduced solid areas, than those of MMTV-PyMT;Ccr2+/− mice (Fig. S1, B and C).

The importance of CCR2 signaling for monocyte recruitment is well understood, but CCR2 is also expressed by human breast cancer cells (Fang et al., 2012). In accordance with this report, we detected Ccr2 mRNA and CCR2 protein in the cancer cells of the tumors developing in MMTV-PyMT;Ccr2+/− mice (Fig. 1, D and E), and using RNA fluorescence in situ hybridization (FISH), we demonstrated that Ccr2 mRNA is expressed by Krt18-positive breast cancer cells (Fig. S1 D). To determine the relative contributions of cancer cell versus host CCR2 to tumor growth, we isolated primary cancer cells (purity >90%; Fig. S1 E) from MMTV-PyMT;Ccr2+/− and MMTV-PyMT;Ccr2−/− mice and transplanted them orthotopically to mammary glands of either Ccr2+/+ or Ccr2−/− syngeneic host mice (Fig. 1 F). Loss of Ccr2 in the host did not alter tumor growth, consistent with our previous report (Nakasone et al., 2012). However, loss of Ccr2 in cancer cells significantly reduced tumor growth rates, leading to approximately twofold longer survival (Fig. 1, G and H). Ccr2 mRNA levels of Ccr2+/− cancer cells were lower than those of Ccr2+/+ cancer cells (Fig. S1 F), and tumors derived from Ccr2+/− cancer cells exhibited the same slow growth as tumors derived from Ccr2−/− cancer cells (Fig. S1 G). This result suggests that a threshold level of CCR2 expression in MMTV-PyMT cancer cells regulates tumor growth.

CCR2+ inflammatory monocytes can promote breast cancer metastasis (Müller et al., 2001; Qian et al., 2011). The overall metastatic burden in the lung—the primary site of metastasis in the MMTV-PyMT model—was, however, very variable in MMTV-PyMT;Ccr2+/− mice and was not significantly different from that of MMTV-PyMT;Ccr2−/− mice (Fig. S1 H). There were also no significant differences in the number of metastatic foci (representing seeding density) related to the Ccr2 genotype (Fig. S1 I). However, we found that the metastatic foci were larger in the lungs of MMTV-PyMT;Ccr2−/− mice than in the lungs of MMTV-PyMT;Ccr2+/− mice (Fig. S1 J), suggesting that CCR2 promotes the growth of secondary lesions.

**Ccr2 expression in cancer cells is associated with poor differentiation and reduced apoptosis sensitivity**

The tumors from transplanted Ccr2+/+ or Ccr2−/− cancer cells were markedly different at the histological level (Fig. 2 A), similar to the autochthonous tumors in the MMTV-PyMT;Ccr2+/− animals (Fig. S1, B and C). The tumors originating from Ccr2+/+ cancer cells consisted entirely of microlobules composed of sheets of large, neoplastic epithelial cells. The microlobules were surrounded by small amounts of fibrovascular stroma containing dense collagen, which is characteristic of poorly differentiated MMTV-PyMT tumors. The neoplastic cells had round-to-oval nuclei, prominent nucleoli, scant cytoplasm, and indistinct cell borders, typical of undifferentiated cells. In contrast, the tumors originating from Ccr2−/− cancer cells were more differentiated. In many areas, the cancer cells contained lipid vacuoles of various sizes. These tumors also had large cystic areas lined by a single or double layer of small, polarized epithelial cells, and the lumina were filled with proteinaceous secretions (Fig. 2 A). Conversely, the tumors originating from Ccr2−/− cancer cells had a reduced percentage of solid areas compared with those originating from Ccr2+/+ cancer cells (Fig. 2 B).

To understand why tumors from Ccr2−/− cancer cells grew more slowly than tumors from Ccr2+/+ cancer cells, we next examined the rates of proliferation and apoptosis in the tumors collected during the phase when Ccr2−/− tumors were growth restricted, 5–6 wk after transplantation. There was no difference in proliferation as determined by nuclear Ki67 staining (Fig. 2 C), and primary Ccr2+/+ and Ccr2−/− cancer cells also grew similarly in vitro (Fig. 2 D). However, we found a higher percentage of cancer cells undergoing apoptosis in tumors from Ccr2−/− cancer cells than from Ccr2+/+ cancer cells (Fig. 2 E). Furthermore, Ccr2−/− cancer cells were more sensitive to serum-free conditions (Fig. 2 F), consistent with a previous study showing that CCR2 signaling can protect cancer cells from apoptosis induced by serum starvation (Fang et al., 2012).

**Ccr2−/− cancer cells have increased expression of interferon (IFN) response genes and of genes involved in MHC class I antigen presentation**

To determine which pathways in the Ccr2−/− cancer cells led to reduced tumor growth and increased cell death, we isolated cancer cells from Ccr2+/+ and Ccr2−/− transplanted tumors formed
Figure 1. Cancer cell Ccr2 promotes primary tumor growth, reducing overall survival. (A) Tumor onset (tumor-free survival) is similar for MMTV-PyMT; Ccr2+/+, MMTV-PyMT;Ccr2+/−, and MMTV-PyMT;Ccr2−/− mice, as determined by weekly palpation and caliper measurement (log-rank [Mantel-Cox] test; n = 28 MMTV-PyMT;Ccr2+/+, 20 MMTV-PyMT;Ccr2+/−, and 18 MMTV-PyMT;Ccr2−/− mice). (B) Primary tumor growth is reduced in MMTV-PyMT;Ccr2+/− and MMTV-PyMT;Ccr2−/− mice compared with MMTV-PyMT;Ccr2+/+ mice, as determined by weekly caliper measurements (Welch’s ANOVA followed by Dunnett’s T3 multiple comparisons test was performed to compare tumor volume at the 8-wk time point [last time point before many MMTV-PyMT;Ccr2+/+ mice were euthanized due to large tumor burden]; n = 21 MMTV-PyMT;Ccr2+/+, 25 MMTV-PyMT;Ccr2+/−, and 18 MMTV-PyMT;Ccr2−/− mice). (C) Time until IACUC-approved endpoint was increased for MMTV-PyMT;Ccr2+/− and MMTV-PyMT;Ccr2−/− mice compared with MMTV-PyMT;Ccr2+/+ mice (log-rank [Mantel-Cox] test, Bonferroni corrected; n = 30 MMTV-PyMT;Ccr2+/+, 35 MMTV-PyMT;Ccr2+/−, and 29 MMTV-PyMT;Ccr2−/− mice). (D) Cancer cells express CCR2 (arrows) as determined by RNA ISH for Ccr2 performed on paraffin-embedded tumor sections from MMTV-PyMT;Ccr2+/+ mice. Image is representative of >10 mice. Scale bar = 20 µm. (E) CCR2 is expressed on epithelial cells, as determined by flow cytometry performed on Ccr2+/+ or Ccr2−/− tumors transplanted to C57BL/6 hosts. Anti-CCR2 primary antibody was gated on EpCAM+ cells and compared with background levels. Left panel shows one representative experiment, and right panel depicts median fluorescence intensity for all experiments (Student’s t test; n = 5). (F) Schematic of transplantation experiments. (G) Primary tumor growth of Ccr2−/− cancer cells is reduced compared with that of Ccr2+/+ cancer cells regardless of the Ccr2 genotype of the host, as determined by weekly caliper measurements (one-way ANOVA was performed for the tumor volume analysis at day 33 [last time point with all Ccr2+/+ hosts transplanted with Ccr2−/− cancer cells alive] and at day 40 [last time point with all Ccr2−/− hosts transplanted with Ccr2+/+ cancer cells alive], followed by Sidak’s multiple comparisons test; n = 5).
in wild-type hosts for equal amounts of time and performed transcriptome profiling by RNA sequencing (RNA-seq). Overall, 520 genes were differentially expressed (adjusted P value <0.05), ∼40% of which were up-regulated in Ccr2−/− cancer cells compared with Ccr2+/+ cancer cells. Among the differentially expressed genes, we detected up-regulation of MHC class I (H2-K1) and Tap1, two genes required for antigen presentation, and IFI27, an IFN response gene, in the Ccr2−/− cancer cells (Fig. 3 A). Vimentin, which is found in poorly differentiated epithelial cells and in mesenchymal cells, was down-regulated in Ccr2−/− cancer cells. This is consistent with a previous study describing a mesenchymal and invasive phenotype in CCR2-expressing cancer cells (Hu et al., 2019). Additionally, gene set enrichment analysis showed robust expression enrichment of the IFN-γ response hallmark gene set, which included genes involved in antigen processing and presentation, in Ccr2−/− cancer cells compared with Ccr2+/+ cancer cells (Fig. 3 B). We also observed a pronounced luminal gene expression signature in the Ccr2−/− cancer cells (Fig. 3 B), in agreement with the noted histological differences (Fig. 2, A and B). Consistently, gene ontology (GO) term analysis revealed altered expression of pathways involved in (1) regulation

Figure 2. Loss of Ccr2 increases apoptosis in vivo with no effect on proliferation. (A) Four representative photomicrographs of H&E-stained tumors derived from Ccr2+/+ and Ccr2−/− cancer cells. Arrows denote cystic areas. Also note lipid vacuoles in tumors from Ccr2−/− cancer cells. Scale bar = 100 µm. (B) Histology score of solid area in tumors from Ccr2+/+ and Ccr2−/− transplants (n = 10 in Ccr2+/+, and n = 8 in Ccr2−/−). (C) Proliferation is unchanged between Ccr2+/+ and Ccr2−/− tumor transplants during the growth-restricted phase, as determined by Ki67-positive nuclear stain. Left panels are representative photomicrographs (scale bar = 100 µm), and right panel shows quantification (n = 10 and 9 for Ccr2+/+ and Ccr2−/− transplants, respectively). (D) Proliferation is unchanged in Ccr2−/− and Ccr2+/+ cancer cells in vitro during the growth-restricted phase, as determined by absorbance after 24 h using CellTiter 96 AQueous One Solution Cell Proliferation (MTS) Assay (n = 4). (E) Ccr2−/− cancer cells have an increased apoptotic index compared with Ccr2+/− cancer cells during the growth-restricted phase, as determined by double immune staining for PyMT and cleaved caspase-3. Left panels are representative photomicrographs, with arrows indicating apoptotic cancer cells (scale bar = 100 µm); right panel shows quantification (n = 5). Each dot represents an average of five random fields of views from one tumor. (F) Ccr2−/− cancer cells are less viable than Ccr2+/− cancer cells in serum-free conditions, as determined by absorbance in MTS assay after serum starvation for 24 h (n = 3). Means ± SEM are indicated. P values were determined by Student’s t test. *, P < 0.05; ***, P < 0.001; ****, P < 0.0001. N.S., nonsignificant.
of the adaptive immune system and in (2) response to immune-mediated cell killing (Fig. 3 C).

**Cancer cell CCR2 promotes immune suppression**

The increased expression of genes associated with IFN response and antigen presentation, together with the prolonged growth delay and increased apoptosis in tumors from Ccr2<sup>−/−</sup> cancer cells, is consistent with an ongoing adaptive immune response in the tumors. We therefore determined whether there were any differences in the infiltrating immune cell populations by flow cytometry (for gating strategy, see Fig. S2). There were significantly more CD8<sup>+</sup> CTLs and fewer CD4<sup>+</sup> helper T cells in tumors from Ccr2<sup>−/−</sup> cancer cells than in tumors from Ccr2<sup>+/+</sup> cancer cells (Fig. 4 A), with no overall change in CD3<sup>+</sup> T cell infiltration (Fig. S3 A). Increased infiltration of CD8<sup>+</sup> cells into tumors derived from Ccr2<sup>−/−</sup> cancer cells was also evident by immunofluorescence (Fig. 4, B and C). PD-1 is an inhibitory checkpoint surface molecule expressed by activated CD8<sup>+</sup> T cells (Chen et al., 2016a), and its expression was increased on CD8<sup>+</sup> T cells from tumors from Ccr2<sup>−/−</sup> cancer cells (Fig. 4 D). CTLs kill, in part, through the release of granzyme B, a process that requires lysosomal-associated membrane protein 1 (LAMP-1; also known as Cluster of Differentiation 107a [CD107a]). In tumors from Ccr2<sup>−/−</sup> cancer cells, LAMP-1 was increased on the cell surface of CD8<sup>+</sup> T cells (Fig. 4 E), while granzyme B levels were reduced in CD8<sup>+</sup> T cells (Fig. 4 F), indicating increased levels of prior CD8<sup>+</sup> degranulation and therefore cytotoxic activity. Regulatory T lymphocytes (CD4<sup>+</sup>FoxP3<sup>+</sup> regulatory T cells), which are typically immunosuppressive, were more abundant in tumors from Ccr2<sup>−/−</sup> cancer cells (Fig. S3 B).

Tumors from Ccr2<sup>−/−</sup> cancer cells had multiple changes in the adaptive immune cell infiltrate, all consistent with an active immune response. Therefore, we tested whether an adaptive immune response contributed to the differences in growth rates between the Ccr2<sup>+/+</sup> and Ccr2<sup>−/−</sup> tumors by transplanting cancer cells in parallel into T cell–deficient athymic (nude) or fully immunocompetent mice (Fig. 5 A). In the immunocompetent hosts, tumors from Ccr2<sup>−/−</sup> cancer cells showed increased growth rates, consistent with a role for adaptive immunity in determining the growth rates of Ccr2<sup>−/−</sup> tumors.
grew significantly more slowly than tumors from Ccr2+/+ cancer cells (Fig. 5 B), as previously observed (Fig. 1 G). In contrast, in the T cell–deficient hosts, the Ccr2−/− tumors grew at a similar rate as the Ccr2+/+ tumors (Fig. 5 C). Consistently, tumors derived from Ccr2−/− cancer cells grew as fast as tumors derived from Ccr2+/+ cancer cells when CD8+ T cells were depleted from wild-type mice (Fig. S3 C). Furthermore, in the T cell–deficient, athymic hosts, tumors from Ccr2−/− cancer cells no longer had more apoptotic cells than tumors from Ccr2+/+ cancer cells (Fig. 5 D). Interestingly, the differentiated histological phenotype of the tumors from the Ccr2−/− cancer cells was maintained in the athymic mice (Fig. 5, E and F). Thus, the histological differences were not the result of an altered adaptive immune response. Together, these data demonstrate that CCR2 expressed by cancer cells enables the tumors to escape the adaptive immune response.

We next speculated that the reduced growth of tumors from Ccr2−/− cancer cells could be a result of increased sensitivity to CTL-induced cell death, given that the Ccr2−/− cancer cells showed increased sensitivity to serum-free conditions and that the tumors grew normally when CD8+ T cells were depleted. To test this possibility, we used the MMTV-PyMT-mCherry-OVA (chOVA) model (Engelhardt et al., 2012), which is driven by the PyMT oncogene and coexpresses OVA as a model tumor antigen and mCherry for tracking. We generated MMTV-PyMT-chOVA; Ccr2+/+ and MMTV-PyMT-chOVA; Ccr2−/− mice and found that similar to the MMTV-PyMT; Ccr2−/− tumors, the MMTV-PyMT-chOVA; Ccr2−/− tumors grew more slowly than MMTV-PyMT-chOVA; Ccr2+/+ tumors (Fig. 6 A). When primary cancer cells were isolated and challenged with activated CTLs isolated from OT-1 mice (where T cells are engineered to recognize an OVA peptide presented by MHC class I molecules), tumors from Ccr2−/− cancer cells were more sensitive to CTL-mediated cell death, as shown by the increased levels of PD-1 and LAMP-1 (CD107a) in CD8+ T cells (Fig. S4 A–D). In contrast, CD8+ T cells in Ccr2+/+ tumors showed increased intracellular granzyme B levels after 2 h of incubation with Brefeldin A (Fig. S4 E and F). Together, these data suggest that CCR2 signaling in cancer cells causes immune evasion.

Figure 4. Tumors derived from Ccr2−/− cancer cells have increased infiltration of activated CTLs. (A) Tumors from Ccr2−/− cancer cells have fewer CD4+ T cells and more CD8+ T cells during the growth-restricted phase, as determined by flow cytometry gated on CD45+CD3+ cells. Left panels are representative examples of dot plots, and right panels show quantification of CD4+ and CD8+ cells (n = 5). (B) Representative immunofluorescence staining showing that more CD8+ T cells (red) infiltrate into tumors derived from Ccr2−/− cancer cells than tumors from Ccr2+/+ cancer cells during the growth-restricted phase (scale bar = 100 µm). (C) Quantification of CD8+ T cells in the tumors (n = 5 tumors; each dot represents the average of five random fields of views of one tumor). (D) PD-1 levels were increased in CD8+ T cells in tumors from Ccr2−/− cancer cells during the growth-restricted phase, as determined by flow cytometry gating on CD45+CD3+CD8+ cells (n = 5). (E) LAMP-1 (CD107a) levels were increased in CD8+ T cells in Ccr2−/− tumors during the growth-restricted phase, as determined by flow cytometry gating on CD45+CD3+CD8+ cells (n = 4 and 5 for Ccr2−/− and Ccr2+/+ transplants, respectively). (F) Intracellular granzyme B levels were decreased in CD8+ T cells in Ccr2−/− tumors during the growth-restricted phase, as determined by flow cytometry gating on CD45+CD3+CD8+ cells, after 2 h of incubation with Brefeldin A (n = 5). Means ± SEM are indicated. P values were determined by Student’s t test. *, P < 0.05 (A and D–F); ***, P < 0.0001 (C).
I), we found that MMTV-PyMT-chOVA;Ccr2−/− cancer cells grow faster than tumors from Ccr2+/+ cancer cells in mice with intact immune systems. Tumor burden was determined by weekly caliper measurements. Mice were sacrificed at IACUC-approved endpoint (n = 20 per condition). 

We measured the clonal expansion of T cells, an indicator of active proliferation of antigen-specific T cells, by sequencing the complementarity determining regions of T cells expanded in vivo from the tumor. 

To test if Ccr2 expression in cancer cells also regulated sensitivity to CTLs in vivo, we measured the clonal expansion of T cells, an indicator of active proliferation of antigen-specific T cells, by sequencing the complementarity determining regions of T cells expanded in vivo from the tumor. 

Figure 5. Cancer cell Ccr2 tumor growth requires functional adaptive immunity. (A) Schematic of experimental design. (B) Tumors from Ccr2+/+ cancer cells grow faster than tumors from Ccr2−/− cancer cells in mice with intact immune systems. Tumor burden was determined by weekly caliper measurements. Mice were sacrificed at IACUC-approved endpoint (n = 20 per condition). (D) Apoptosis was unchanged between Ccr2+/+ and Ccr2−/− transplants to athymic hosts, as determined by TUNEL stain. Left panels are representative photomicrographs (scale bar = 100 µm), with arrows pointing to apoptotic cells; right panel shows quantification (n = 8 and 6 for Ccr2+/+ and Ccr2−/− transplants, respectively). (E) Representative H&E staining of transplanted tumors from Ccr2+/+ and Ccr2−/− cancer cells to nude hosts. Arrows indicate highly necrotic areas (scale bar = 100 µm). (F) Histology score of solid area of transplanted tumors from Ccr2+/+ and Ccr2−/− cancer cells to athymic hosts (n = 10 in Ccr2+/+ and n = 9 in Ccr2−/−). Means ± SEM are indicated. P values were determined by t test with Welch’s correction (B) or by Student’s t test (C) for tumor volume analysis at the end time point and by Student’s t test (D and F). *, P < 0.05; **, P < 0.01. N.S., nonsignificant.

We found that the CCR2 inhibitor also increased specific cytolysis of the OVA-expressing E0771 murine breast cancer cell line to the OVA-specific CTLs (Fig. S3 D). In contrast, the CCR2 inhibitor had no effect on the specific cytotoxicity of the CTLs to the MMTV-PyMT-chOVA;Ccr2−/− cancer cells (Fig. 6 C).

To test if Ccr2 expression in cancer cells also regulated sensitivity to CTLs in vivo, we measured the clonal expansion of T cells, an indicator of active proliferation of antigen-specific T cells, by sequencing the complementarity determining regions of T cells expanded in vivo from the tumor.

Fein et al. CCR2 signaling in cancer cells causes immune evasion
region 3 (CDR3) region of the T cell receptor (TCR) β chain. We found that clonality, a value corresponding to the extent of clonal expansion of T cells (Fig. 6 D), was significantly higher in tumors from Ccr2−/− cancer cells than in tumors from Ccr2+/+ cancer cells (Fig. 6 E), while there was no difference in clonality in the spleens of these groups of mice (Fig. 6 F). These results suggested that tumor-recognizing CTLs were actively expanding due to antigen recognition in tumors from Ccr2−/− cancer cells, but that this expansion did not alter the systemic T cell response. Both Ccr2+/+ and Ccr2−/− cancer cells express the PyMT tumor antigen, and Ccr2+/+ cancer cells formed tumors at the same rate regardless of whether Ccr2+/+ or Ccr2−/− cancer cells were transplanted to the contralateral mammary gland (Fig. S3 E). Together, these results suggest that the expression of CCR2 by cancer cells enables the tumors to establish a locally immune-suppressive microenvironment.

Cancer cell CCR2 alters MHC class I and PD-L1 expression

CCR2 signaling can activate STAT transcription factors in cancer cells (Chen et al., 2015; Izumi et al., 2013), and altered
STAT1 or STAT3 signaling in cancer cells can in turn lead to a less immune-suppressive microenvironment (Ahn et al., 2017; Jones et al., 2016). Therefore, we tested whether STAT activation was different between tumors from $Ccr2^{+/+}$ and $Ccr2^{-/-}$ cancer cells. We found no consistent differences between the activation of STAT1, STAT3, or p65/RELA when whole tumor lysate was assayed by Western blot (Fig. 7 A). By immunohistochemistry, we found that the tumors contained patches of cancer cells with high expression of phospho-STAT1, with more of these patches in the tumors from $Ccr2^{-/-}$ than in those from $Ccr2^{+/+}$ cancer cells but similar levels of STAT3 phosphorylation ($n=5$). Means ± SEM are indicated. P values were determined by Student’s t test. *, $P < 0.05$. N.S., nonsignificant.

We next sought to understand how CCR2 signaling in cancer cells resulted in more efficient immune suppression. RNA-seq analysis of the cancer cells showed increased expression of genes involved in antigen presentation in the $Ccr2^{-/-}$ tumors (Fig. 3 A). Consistently, we found high levels of MHC class I expressed by cancer cells in MMTV-PyMT-chOVA;$Ccr2^{-/-}$ mice compared with the variable, low to intermediate levels expressed by cancer cells in MMTV-PyMT-chOVA;$Ccr2^{+/+}$ mice (Fig. 8 A). Similarly, when cancer cells were transplanted to immunocompetent host mice, expression of MHC class I was higher by $Ccr2^{-/-}$ cancer cells than by $Ccr2^{+/+}$ cancer cells, as shown by immunofluorescence (Fig. 8 B). However, in T cell–deficient, athymic host mice, MHC class I levels were similar on $Ccr2^{+/+}$ and $Ccr2^{-/-}$ cancer cells (Fig. 8 C). These data suggest that MHC class I expression is not directly regulated by CCR2 signaling in the...
Figure 8. MHC class I expression is reduced and PD-L1 expression increased in Ccr2−/+ cancer cells in immunocompetent mice. (A) MHC class I expression is increased in MMTV-PyMT-chOVA;Ccr2−/− tumors compared with MMTV-PyMT-chOVA;Ccr2+/+ tumors during the growth-restricted phase, as determined by immunofluorescence staining (upper panels: representative images; scale bar = 50 µm) and by flow cytometry (bottom panel), gated on EpCAM+,mCherry+ cells (n = 8 and 4 for PyMT-chOVA;Ccr2−/− and PyMT-chOVA;Ccr2+/+ tumors, respectively). (B) MHC class I is increased on Ccr2−/− compared with Ccr2+/+ cancer cells after transplantation into C57BL/6 hosts during the growth-restricted phase, as determined by immunofluorescence staining (upper panels; scale bar = 50 µm). Quantification of mean pixel count (bottom panel, n = 5). (C) MHC class I is unchanged on Ccr2+/+ and Ccr2−/− cancer cell transplants to athymic hosts, as determined by immunofluorescence staining (upper panels; scale bar = 50 µm). Quantification of mean pixel count (bottom panel, n = 4 and 5 for Ccr2+/+ and Ccr2−/− transplants, respectively). (D) PD-L1 is decreased on Ccr2−/− cancer cells, as determined by flow cytometry gated on EpCAM+ cells (n = 5). (E) PD-L1 mRNA levels are decreased in cultured Ccr2−/− cancer cells, but the cells respond equally well to IFN-γ treatment as Ccr2+/+ cancer cells, as determined by qPCR. Ccr2+/+ and Ccr2−/− cancer cells growing in culture were treated with either 0, 0.2, 2.0, or 20 ng/ml of recombinant IFN-γ for 48 h (n = 3). (F) Treatment with four intraperitoneal doses of anti–PD-L1 antibody (200 µg/injection) had no significant effect on growth of Ccr2+/+ or Ccr2−/− tumors in vivo compared with control rat IgG antibody (arrows indicate treatments; n = 20 tumors for all conditions). Means ± SEM are indicated. P values were determined by Student’s t test (A–E) or Student’s t test on day 58 for Ccr2−/− transplants (black lines in F) and at day 75 for Ccr2−/− transplants (red lines in F). *, P < 0.05; **, P < 0.01; ***, P < 0.001. N.S., nonsignificant.
cancer cells, but rather is regulated by the different immune responses between these tumors.

PD-L1 is a potent suppressor of T cell activation and proliferation and is expressed on many types of cancer cells (Freeman et al., 2000). Expression of PD-L1 was significantly higher on Ccr2<sup>−/−</sup> cancer cells than on Ccr2<sup>+</sup> cancer cells (Fig. 8 D). Since both MHC class I and PD-L1 are IFN-γ response genes, we compared Ifn-γ mRNA levels during the early tumor phase (3 wk after transplantation) and found significantly higher levels of Ifn-γ, as well as Cxcl9, in whole tumor lysate from tumors derived from Ccr2<sup>−/−</sup> compared with Ccr2<sup>+/−</sup> cancer cells by real-time quantitative PCR (RT-qPCR; Fig. S4 A). RNA FISH revealed that the majority of the Ifn-γ mRNA was expressed by infiltrating CD8<sup>+</sup> T cells and that Ifn-γ levels were more variable during the growth-restricted phase of tumors than during the early tumor establishment phase (Fig. S4, B–D). In vitro, recombinant IFN-γ treatment resulted in similar up-regulation of Pd-lt mRNA levels in Ccr2<sup>−/−</sup> and Ccr2<sup>+/−</sup> cancer cells (Fig. 8 E).

Thus, our data suggest that Ccr2<sup>+/−</sup> cancer cells would be able to respond to increased IFN-γ levels in the tumor microenvironment by up-regulating PD-L1. Since we see reduced PD-L1 expression on the Ccr2<sup>−/−</sup> cancer cells in vivo in the context of elevated Ifn-γ, other factors must repress PD-L1 expression in vivo. Lastly, we tested whether PD-L1 blockade would alleviate immune suppression of the MMTV-PyMT tumors in vivo. However, anti-PD-L1 therapy had no significant effect on the growth of either the Ccr2<sup>−/−</sup> or the low PD-L1–expressing Ccr2<sup>+/−</sup> tumors (Fig. 8 F). Thus, although reduced PD-L1 likely contributed to an increased sensitivity to CTLs in tumors from Ccr2<sup>−/−</sup> cancer cells, targeting PD-L1 expression was insufficient to reduce growth of the Ccr2<sup>−/−</sup> tumors.

Cancer cell CCR2 prevents the infiltration of cross-presenting CD103<sup>+</sup> DCs

We next examined the infiltration levels of immune populations that might be involved in immune suppression in the Ccr2<sup>−/−</sup> tumors. There was no difference in CD11b<sup>+</sup>MHC class II<sup>+</sup>F4/80<sup>+</sup> macrophages between tumors from Ccr2<sup>−/−</sup> and Ccr2<sup>+/−</sup> cancer cells (Fig. S4 E). There were, however, significantly fewer CD11b<sup>+</sup>MHC class II<sup>+</sup> myeloid cells in tumors from Ccr2<sup>−/−</sup> cancer cells (Fig. S4 F). This population includes subsets of MDSCs, immature myeloid cells with immune-suppressive activity. Specifically, we found fewer granulocytes and granulocytic MDSCs (CD11b<sup>+</sup>CD11c<sup>+</sup>Ly6G<sup>+</sup>Ly6C<sup>high</sup> cells) and more inflammatory monocytes and myeloid MDSCs (CD11b<sup>+</sup>CD11c<sup>+</sup>Ly6G<sup>−</sup>Ly6Chigh cells) in tumors from Ccr2<sup>−/−</sup> cancer cells than those from Ccr2<sup>+/−</sup> cancer cells (Fig. S4, G and H).

Since DCs are critical for T cell activation, we performed immunofluorescence for CD11c<sup>+</sup>, a marker of DCs, and observed more infiltrating CD11c<sup>+</sup> cells in the tumors derived from Ccr2<sup>−/−</sup> cancer cells than in those derived from Ccr2<sup>+/−</sup> cancer cells (Fig. 9 A). Furthermore, we found more than double the level of CD103<sup>+</sup> DCs—a DC subtype that is very proficient in cross-presenting antigens to CD8<sup>+</sup> T cells—in tumors from Ccr2<sup>−/−</sup> cancer cells than in those from Ccr2<sup>+/−</sup> cancer cells (Fig. 9 B). The number of CD103<sup>+</sup> DCs was also increased in the draining lymph nodes (dLN)s for these tumors (Fig. 9 C). A concern when using a transplant system to evaluate immune response is the potential for an immune reaction toward antigens on the transplanted cells. However, there were also more CD103<sup>+</sup> DCs in the spontaneously developing tumors in MMTV-PyMT;Ccr2<sup>+/−</sup> mice than in MMTV-PyMT;Ccr2<sup>−/−</sup> mice (Fig. S4 I). Using RT-qPCR from whole tumor lysate and a panel of markers previously shown to be enriched in CD103<sup>+</sup> DCs (Broz et al., 2014), we detected more mRNA for Cd11c and from activation markers, including Cd80, Cd86, and Il12b (Fig. 9 D). Consistently, DCs in tumors from Ccr2<sup>−/−</sup> cancer cells displayed higher levels of CD86, a surface marker up-regulated on activated DCs as determined by flow cytometry (Fig. 9 E). The difference in CD103<sup>+</sup> DC numbers was already apparent in the dLN s 2 d after injection of irradiated cancer cells into the mammary fat pad (Fig. 9 F), suggesting a direct signal from the cancer cells. However, infiltration of CD103<sup>+</sup> DCs was not increased in tumors from Ccr2<sup>−/−</sup> cancer cells in T cell–deficient, athymic mice (Fig. 9 G). This finding suggests that a feedback loop between T cells and DCs is critical for CD103<sup>+</sup> DC recruitment to the tumors.

We next asked whether a factor secreted by Ccr2<sup>−/−</sup> cancer cells was responsible for DC maturation toward the CD103<sup>+</sup> DC subtype. Indeed, when bone marrow–derived cells (BMDCs) were cultured with conditioned medium from Ccr2<sup>−/−</sup> or Ccr2<sup>+/−</sup> cancer cells, the total number of DCs was not different, but a significantly higher percentage of CD11c<sup>+</sup> cells was positive for CD103<sup>+</sup> using conditioned medium from the Ccr2<sup>−/−</sup> cells (Fig. 10 A). Furthermore, the percentage of CD103<sup>+</sup>CD11c<sup>+</sup> cells also increased when using conditioned medium from Ccr2<sup>−/−</sup> cancer cells that had been treated with the CCR2 inhibitor (Fig. 10 B), whereas adding the CCR2 inhibitor directly to the bone marrow–derived cultures did not by itself increase the percentage of CD103<sup>+</sup> cells. Both Flt3 ligand and GM-CSF can stimulate DC maturation toward the CD103<sup>+</sup> subtype (Broz et al., 2014). Consistently, we found more mRNA for both Flt3l and Csf2 (coding for GM-CSF) in the tumors derived from Ccr2<sup>−/−</sup> cancer cells than from Ccr2<sup>+/−</sup> cancer cells by RT-qPCR (Fig. 10 C). Protein arrays showed that the levels of two CCR2 ligands, CCL2 and CCL12, and most other cytokines were similar between MMTV-PyMT;Ccr2<sup>−/−</sup> and MMTV-PyMT;Ccr2<sup>+/−</sup> tumors (Fig. S5 A), while IL-16 and granulocyte colony-stimulating factor (G-CSF) were significantly lower in the MMTV-PyMT;Ccr2<sup>−/−</sup> tumors at the protein level. When secretions from overnight cultures of the cancer cells under serum-free conditions were analyzed, no significant differences were detected (Fig. S5 B). Thus, from these different assays measuring protein and mRNA, Flt3l, G-CSF, and GM-CSF emerged as candidate factors for future functional studies to determine how CD103<sup>+</sup> DC maturation is altered downstream of CCR2 signaling in cancer cells.

Lastly, to test the importance of the CD103<sup>+</sup> DCs in regulating an immune-controlling microenvironment, we transplanted Ccr2<sup>−/−</sup> and Ccr2<sup>+/−</sup> cancer cells into Batf3<sup>−/−</sup> mice, which lack the basic leucine zipper transcription factor ATF-like 3 (BATF3) critical for CD103<sup>+</sup> DC maturation. In these mice, the growth of Ccr2<sup>−/−</sup> cancer cell–derived tumors was restored to that of the Ccr2<sup>−/−</sup> cancer cell–derived tumors (Fig. 10 D), and as expected, the percentage of infiltrating CD103<sup>+</sup> DCs was significantly reduced (Fig. 10 E). Furthermore, CD8<sup>+</sup> T cell infiltration, as well as

Fein et al.

CCR2 signaling in cancer cells causes immune evasion
expression of CD107a and PD-1 by the T cells, was reduced in tumors derived from Ccr2−/− cancer cells transplanted into Batf3−/− mice (Fig. 10, F–H). These findings support the notion that CD103+ DC and CD8+ T cells act together to regulate tumor immunity.

Discussion

The tumor-promoting effects of CCR2 are well documented. However, they have mostly been attributed to CCR2-expressing immune and other host cells (Lim et al., 2016; Nakasone et al., 2012; Qian et al., 2009, 2011; Wolf et al., 2012). Yet, CCR2 is also expressed by breast cancer cells and possibly up-regulated compared with normal breast epithelial tissue in a subset of breast cancers, and such expression has been correlated with shortened survival (Labovsky et al., 2017). The expression of CCR2 by cancer cells has been proposed to promote tumor growth through increased motility and invasion, cell proliferation, and cell survival (Fang et al., 2012; Hu et al., 2019; Lu et al., 2006). Here, we showed that in the MMTV-PyMT mouse model, CCR2 signaling in cancer cells helps breast tumors establish a locally immune-suppressive microenvironment. Compared with tumors from Ccr2+/+ cancer cells, the tumors from Ccr2−/− cancer cells have higher infiltration of CD103+ DCs and activated CD8+ T cells, as well as lower infiltration of granulocytic MDSCs. Furthermore, the Ccr2−/− cancer cells have higher surface levels of MHC class I and lower levels of PD-L1. It is likely the combination of all of these changes that results in more effective...
immune surveillance of the Ccr2−/− cancer cells and reduced growth of tumors from these cells. To our knowledge, the ability of cancer cell CCR2 signaling to orchestrate tumor immune suppression has not previously been recognized.

Among the most notable changes in the tumor immune microenvironment caused by targeting cancer cell Ccr2 were the increased levels of both CD103+ DCs and CD8+ T cells in tumors, and the infiltration of these two cell populations was apparently connected. In athymic mice lacking mature CD8+ cells, the CD103+ DC infiltration was no longer elevated in tumors derived from Ccr2−/− cancer cells compared with those from Ccr2+/+ cancer cells. Conversely, in Batf3−/− mice, which lack the transcription factor BATF3 required for CD103+ DC development, CD8+ T cell infiltration was equally low for tumors from Ccr2−/− and Ccr2+/+ cancer cells. These observations are consistent with several other recent reports intimately linking the function of CD103+ DCs and CD8+ T cells in tumors. First, CD103+ DCs have been shown to secrete chemokines mediating T cell infiltration, including CXCL9 and -10 (de Mingo Pulido et al., 2018; Spranger et al., 2017). Second, secretion of IL-12 from CD103+ DCs has been shown to stimulate CD8+ T cell function (Ruffell et al., 2014). Our data support these previous studies, showing not only a link between CD103+ DC and CD8+ T cell infiltration but also increased Cxcl9 and Il-12b mRNA in tumors derived from Ccr2−/− cancer cells. Altogether, these data support previous work showing that the regulation of CD103+ DC infiltration is a critical step in tumor immune surveillance (Broz et al., 2014; Meyer et al., 2018; Roberts et al., 2016).
Our data suggest that CCR2 signaling regulates the secretion of a factor from the cancer cells that affects the polarization of DCs to the CD103+ subtype. Several factors have been proposed to induce the polarization of CD103+ DCs, including Flt3L and GM-CSF (Mayer et al., 2014), and consistently, mRNA levels for both of these factors were higher in tumors from Ccr2−/− cancer cells than in those from Ccr2+/+ cancer cells. However, it is unclear if Flt3L and GM-CSF could be solely responsible for the difference in CD103+ DC infiltration between tumors from Ccr2−/− or from Ccr2+/+ cancer cells. A recent study reported that G-CSF secreted from MMTV-PyMT cancer cells can inhibit the differentiation of CD103+ DCs by down-regulating IFN regulatory factor-8 in DC progenitors (Meyer et al., 2018). Interestingly, G-CSF was reduced in MMTV-PyMT;Ccr2−/− tumors compared with MMTV-PyMT;Ccr2+/+ tumors, although secretion of G-CSF from isolated cancer cells was not reduced, suggesting that altered secretion is not a direct effect of CCR2 signaling in cancer cells.

Ccr2−/− cancer cells had distinct expression of several genes, including many that were consistent with an IFN response. Among these, increased surface expression of MHC class I might explain why Ccr2−/− cancer cells are more sensitive to T cell-mediated killing than Ccr2+/+ cancer cells. However, since Ccr2−/− cancer cells did not down-regulate MHC class I in T cell-deficient, athymic mice, we speculate that MHC class I expression is not directly regulated by CCR2 signaling in the cancer cells. Rather, the altered expression of IFN response genes, including MHC class I, may be an indirect result of an immune response in the tumors. Altogether, we propose that the cancer cells act on CD103+ DCs, leading to a feedback loop between CD103+ DCs and CD8+ T cells—two immune cell types with highly interconnected functions.

Our study has several translational implications. First, our findings provide a possible explanation as to why patients with high CCR2 expression in breast cancer cells have a shortened survival time compared with patients with low/negative CCR2 expression (Labovsky et al., 2017). Second, results from an open-label nonrandomized phase I trial using a CCR2 inhibitor against locally invasive pancreatic cancer suggest that the inhibitor enhanced chemotherapy response, reduced macrophage infiltration, and induced an anti-tumor adaptive immune response (Nywening et al., 2016). Our data suggest that the potential clinical benefits of CCR2 inhibitors might be caused by the combined inhibition of CCR2 signaling in both stromal and cancer cells. Interestingly, the loss of even one Ccr2 allele was sufficient to reduce tumor growth in our study, suggesting that partial inhibition of CCR2 could result in clinical benefit. It is unclear why Ccr2−/− cancer cells phenocopy the Ccr2−/− cancer cells, but this phenomenon could be due to reduced dimerization of CCR2 in Ccr2−/− cancer cells, consistent with a prior report (Rodriguez-Frade et al., 1999), or because surpassing a threshold level of CCR2 signaling is required to induce immune suppression. Finally, recombinant G-CSF and GM-CSF are routinely given with certain types of chemotherapy to support the bone marrow and reduce the risk of lethal febrile neutropenia (Mehta et al., 2015). Our data support prior studies suggesting that these cytokines play complex roles in regulating the immune response against tumors: they appear to have opposing effects on CD103+ DC differentiation, with GM-CSF stimulating CD103+ DC differentiation (Greter et al., 2012; Mayer et al., 2014) and G-CSF inhibiting it (Meyer et al., 2018). Although GM-CSF secretion in the tumor microenvironment potentially enhances immune responses against tumors by stimulating CD103+ DC differentiation, this cytokine can also mobilize immune-suppressive MDSCs, leading to suppression of an anti-tumor immune response (Bayne et al., 2012; Fylaye-Gupta et al., 2012). Therefore, exploring other approaches than administration of recombinant GM-CSF and G-CSF to specifically boost CD103+ DC maturation could be an important future translational direction, and determining the exact mechanism that causes inhibition of cancer cell CCR2 signaling to promote CD103+ maturation may provide insights into how this process occurs.

We found that tumor onset was similar between MMTV-PyMT;Ccr2−/− and MMTV-PyMT;Ccr2+/+ mice, while tumor growth was slower in MMTV-PyMT;Ccr2−/− mice. These data are very similar to a prior report studying tumor growth in MTMV-Neu mice, where mice null for Ccl2, the ligand for CCR2, also had similar tumor onset yet reduced tumor growth rates, as did mice treated with a CCR2 inhibitor (Chen et al., 2016b). However, unexpectedly, MMTV-Neu mice lacking Ccr2 had accelerated, not reduced, tumor growth in this study, and the authors speculated that this could be due to abnormal differentiation of the monocytes in these mice or unintentional effects of the genetic targeting of Ccr2. There are several possible explanations for the difference between our result using MMTV-PyMT;Ccr2−/− mice and that of the MMTV-Neu:Ccr2−/− mice in the previous publication. First, tumors of MMTV-PyMT mice have more stromal components than tumors of MMTV-Neu mice. Second, the genetic background of the mice used in our experiments was C57BL/6, while it was BALB/c in the case of the MMTV-Neu model. Finally, our tumor transplantation experiments strongly suggest that the tumor growth phenotype in our model is caused by CCR2 expression by cancer cells, but it is not clear whether cancer cells in the MMTV-Neu model express CCR2 or whether the phenotype is due to effects from stromal cells.

Despite the data suggesting that CCR2 inhibition has beneficial effects in cancer treatment, some studies have raised serious concerns about targeting the CCR2 ligand. Cessation of anti-CLL2 therapy resulted in increased pulmonary metastasis and decreased survival in a murine model of breast cancer due to rapid mobilization of CCR2-expressing monocytes into the circulation immediately upon cessation of therapy (Bonapace et al., 2014). Therefore, CCR2 inhibition likely will have to be used in combination with other therapies to maximize the eradication of existing cancer cells and to avoid complications of discontinuing the inhibition. In summary, the divergent results across mouse models, genetic backgrounds, and variable experimental approaches to targeting CCL2 or CCR2 suggest that the effects of targeting this axis can depend on tumor subtype, genetic background, and cell types.

Our findings support the notion that the CCL2/CCR2 axis is an immune modulatory pathway in cancer, but with the added layer of complexity that cancer cells can hijack this chemokine
receptor pathway to orchestrate immune suppression. In this study, we focused on characterizing the cellular mechanisms responsible for the novel link between cancer cell CCR2 signaling and tumor immune suppression. Preclinical experiments suggest that CCR2 targeting strategies can have detrimental effects, including the promotion of metastasis (Bonapace et al., 2014; Li et al., 2013). Although we observed no effect of anti-PD-L1 antibodies in combination with CCR2 deletion in cancer cells, anti-PD-L1 antibodies in combination with CCR2 inhibition (which also targets CCR2 on myeloid cells) reduced MDSC infiltration and increased survival in a mouse model of glioma (Flores-Toro et al., 2020). Therefore, future work that identifies the precise mechanisms by which CCR2 signaling in cancer cells induces immune suppression in breast cancer may set the stage for developing novel immune modulatory therapies. There are ongoing clinical trials using pharmacological inhibitors of CCR2 in cancer patients, and our data suggest that the potential effects of inhibiting CCR2 signaling in cancer cells should be taken into account when interpreting the results from these trials.

Materials and methods

Mice

Cr2<sup>−/−</sup>, Batf3<sup>−/−</sup>, and OT-1 mice (all on a C57BL/6 background) were obtained from Jackson Laboratory, and athymic (Nu/Nu) mice were obtained from Charles River Laboratory. MMTV-PyMT mice (on C57BL/6 [referred to as BL/6] background) were bred at Cold Spring Harbor Laboratory (CSHL), and MMTV-PyMT-chOVA mice (Engelhardt et al., 2012) were a kind gift from Dr. Mathew Krummel (University of California, San Francisco, San Francisco, CA). MMTV-PyMT and PyMT-chOVA mice were intercrossed with Cr2<sup>−/−</sup> mice. MMTV-PyMT,Cr2<sup>−/−</sup> and MMTV-PyMT,Cr2<sup>−/−</sup>, and similarly MMTV-PyMT-chOVA,Cr2<sup>−/−</sup> and MMTV-PyMT-chOVA,Cr2<sup>−/−</sup>, mice, were from the same mouse colony (mice were littermates, or their parents were littermates). All the BL/6 host mice were purchased from Jackson Laboratory. All animal experiments were approved by the Institutional Animal Care and Use Committee (IACUC) at CSHL and were conducted in accordance with the National Institutes of Health Guide for the Care and Use of Laboratory Animals.

Measurement of in vivo tumor growth and lung metastasis

Tumor onset was determined by weekly palpation. Once a tumor was detected, its size was measured weekly by caliper, and tumor volume was calculated as (length × width<sup>2</sup>) / 2. For primary tumor growth, mice were either sacrificed at endpoint, when tumors reached 20 mm or ulcerated (whichever came first), or at indicated time points (early phase: 3 wk after transplantation; growth-restricted phase: 5–6 wk after transplantation). For the lung metastasis assay, mice were sacrificed at either of two IACUC-approved endpoints (when tumors reached 25 mm or ulcerated). To determine metastatic burden, we adapted a previously published method (Nielsen et al., 2001). Briefly, lungs were placed in 4% paraformaldehyde (PFA) in PBS in a vacuum desiccator for 1 h. The lungs remained in 4% PFA at 4°C for 48 h, followed by incubation in 20% sucrose in PBS at 4°C for 48 h. Lungs were embedded in Tissue-Tek optimal cutting temperature compound embedding solution (Sakura). The blocks were then placed in a custom-made cutting chamber with razor blade inserts every 2 mm, and the block was cut into 2-mm sections. These sectioned lung pieces were then reembedded in fresh optimal cutting temperature compound to allow for cross-sectional cuts from the entire lung tissue. These cross sections of the lungs were stained with H&E and scanned by an Aperio ScanScope CS System (Leica Biosystems). The metastatic burden was calculated as the percentage of metastasis/lung area and the number of foci/lung area, determined using Aperio eSlide Capture Devices software (Leica Biosystems). Histology was evaluated by pathologist J.E. Wilkinson and scored as percentage of solid areas of tumors.

Primary cancer cell isolation, culture, and transplantation

Aged-matched virgin females (C57BL/6, Cr2<sup>−/−</sup>, Batf3<sup>−/−</sup>, or Nu/Nu) 6–12 wk of age were used as hosts for transplantation. Cancer cells were isolated from two or three tumors, each one 8–10 mm in diameter, from MMTV-PyMT,Cr2<sup>−/−</sup> or MMTV-PyMT,Cr2<sup>−/−</sup> mice. Tumors were mechanically dissociated and digested for 1 h with 1× collagenase/hyaluronidase (10X Solution; Stem Cell Technology) containing DNase I (2 U/ml; Roche) in Roswell Park Memorial Institute (RPMI)-1640 medium supplemented with 5% FBS (VWR Life Science Seradigm). Single cells and debris were removed from the resulting carcinoma organoid preparation by pulse centrifugation in HBSS supplemented with 5% FBS. Purified carcinoma organoids were dissociated into single-cell suspension in 0.05% trypsin with 0.1% EDTA supplemented with 2 U/ml of DNase I for 2–3 min. Single tumor cells were plated through a 100-μm cell strainer (BD Biosciences) and either plated in RPMI-1640 supplemented with 10% FBS for in vitro experiments or washed with PBS and immediately injected into the inguinal mammary glands of host mice (2.5 × 10<sup>5</sup> in 20 μl of 1:1 PBS/Matrigel; Corning).

To evaluate the effect of cancer cell Ccr2 on the anti-tumor immune response locally versus systemically, contralateral transplantation was conducted with cancer cells with different Ccr2 genotypes transplanted into each inguinal mammary gland (2.5 × 10<sup>5</sup> in 20 μl of 1:1 PBS/Matrigel). Cancer cells were isolated as described above, and both C57BL/6 and Ccr2<sup>−/−</sup> mice were used as hosts.

To transplant irradiated cancer cells, freshly isolated primary MMTV-PyMT,Cr2<sup>−/−</sup> or MMTV-PyMT,Cr2<sup>−/−</sup> cancer cells were plated in a 10-cm Petri dish (2 × 10<sup>6</sup> per dish) in RPMI with 10% FBS and received 80 Gy of irradiation in the Gammacell 40 Exactor (Best Theratronics). After irradiation, cancer cells were washed with PBS and injected into the inguinal mammary glands of host mice (2.5 × 10<sup>5</sup> in 20 μl of PBS). To generate cancer cell–conditioned medium, primary cancer cells from either MMTV-PyMT,Cr2<sup>−/−</sup> or MMTV-PyMT,Cr2<sup>−/−</sup> tumors were plated in a 10-cm dish (2 × 10<sup>6</sup> per dish) in DMEM/F12 medium plus 10% FBS and 1% penicillin/streptomycin, with or without CCR2 antagonist (RS504393; 10 μM; Sigma-Aldrich) for 2 d. The conditioned medium was collected and centrifuged at 300 × g for 10 min, and the supernatant was used in experiments.
In vivo antibody treatment

Tumor cells from MMTV-PyMT;Ccr2−/− or MMTV-PyMT;Ccr2+/− mice were transplanted as described above. For anti-PD-L1 treatment, on days 15, 18, 21, and 24 after transplantation (after tumors had formed), mice received 200 μg of anti-PD-L1 antibody by intraperitoneal injection (Clone 10F.9G2; Bio X Cell) or control rat IgG2b antibody (Bio X Cell; Winograd et al., 2015). For CDB8+ T cell depletion, mice were injected intraperitoneally with 200 μg of anti-CD8a antibody (Clone 2.43; BE0061; Bio X Cell) or control rat IgG2b antibody (Clone LIT-2; BE0090; Bio X Cell) every 3 days starting from day 0 and until day 30. Tumor size was measured biweekly, and mice were sacrificed at the IACUC-approved endpoint.

Flow cytometry

Tumors were harvested and mechanically dissociated for 30 min with collagenase D (2 mg/ml; Sigma-Aldrich) and DNase I (4 U/ml) in RPMI. For flow cytometry of cells from lymph nodes, the lymph nodes were forced through a 100-μm cell strainer, and flow-through cells were collected for experiments. Cells were resuspended in 1 × HBSS supplemented with 0.5% BSA and centrifuged at 300 × g. The cell suspension was filtered through a 70-μm cell strainer, and red blood cells were lysed using red blood cell lysing buffer (Sigma-Aldrich) for 1 min at room temperature.

For flow cytometry staining, cells (1 × 10^6) were incubated with mouse Fc Block (clone 2.4G2; BD Biosciences) for 10 min on ice, and then stained with the appropriate antibodies to surface markers at 4°C for 30 min in the dark or permeabilized and stained with intracellular antibodies overnight (see below for antibodies). Cell viability stains Zombie Red (BioLegend) was used to differentiate between dead and live cells. The stained cells were resuspended in 1 × HBSS supplemented with 0.5% BSA and centrifuged at 300 × g. The cell suspension was filtered through a 70-μm cell strainer, and red blood cells were lysed using red blood cell lysing buffer (Sigma-Aldrich) for 1 min at room temperature.

RNA purification and RT-qPCR analysis

Total RNA from cancer cells (cultured 48 h in RPMI supplemented with 10% FBS) or primary tumors was extracted using an RNAeasy kit (Qiagen), following the manufacturer’s instructions. RNA was quantified using a Nanodrop 2000 spectrophotometer (Thermo Fisher Scientific). Reverse transcription was performed using an ImProm-II Reverse Transcription System (Promega) for the cancer cells or the RevertAid First Strand cDNA Synthesis system (K1622; Thermo Fisher Scientific) for the primary tumors, with the following cycling conditions: 5 min at 70°C, 10 min at 4°C, 5 min at 25°C, 60 min at 42°C, and 15 s at 70°C using 1 μg total RNA extract for 20 μl of final volume. RT-qPCR analysis was performed using a TaqMan gene expression assay (Thermo Fisher Scientific) with the following specific primers: Ccr2: Mm00438270_m1; Flt3: Mm00442801_m1; Flt3l: Mm00441242_m1; Csf1: Mm00434946_m1; Cxcl9: Mm00434946_m1; Cxcl10: Mm00445235_m1; Cxcl12: Mm00438259_m1; Prf1: Mm00812512_m1; Clec9a: Mm00554956_m1; Clec9b: Mm00434946_m1; Clec9d: Mm00445235_m1; Cx3r1: Mm00438259_m1; Cxcl9: Mm01996749_s1; Cxcl10: Mm00449698_m1; Cxcl12: Mm00441891_m1; Cxcl8: Mm00711660_m1; Cxcl12: Mm00444543_m1; Cxcl9: Mm01302427_m1; I1-12b: Mm00128899_m1; Tim3: Mm00435450_m1; Csf2: Mm01290062_m1; Fasl: Mm00442820_m1; Fasl: Mm00439016_m1; Ccl2: Mm00441242_m1; Csf3: Mm004338334_m1; Csf1: Mm00432686_m1; and Tbp: Mm01277042_m1.

For cancer cells, RT-qPCR was performed on three independently isolated cancer cell populations and in triplicate for each sample. To determine the effects of IFN-γ on Flt3 expression, cancer cells were cultured with the indicated concentration of IFN-γ (#485-MI-100; R&D Systems) for 48 h before isolation of RNA. For tumor samples, RT-qPCR was performed on at least five primary tumors from different mice and in triplicate for each sample. Relative quantitation was performed using the 2^(-ΔΔCt) method using β-Actin or Tbp expression for normalization and MMTV-PyMT;Ccr2−/− cancer cells or tumor samples as a reference sample.

Cytokine array

Tumors (8-10 mm in diameter) were isolated from MMTV-PyMT;Ccr2−/− and MMTV-PyMT;Ccr2+/− mice and immediately snap-frozen in liquid nitrogen. They were then homogenized in PBS with the addition of protease inhibitors (Promega). Proteome Profiler Mouse Cytokine Array Kit, Panel A (R&D Systems) was used according to the manufacturer’s instructions. Films were scanned, and spots were analyzed using ImageJ software.

MTS (3-[4,5-Dimethylthiazol-2-yl]-5-[3-carboxymethoxyphenyl]-2-[4-sulfophenyl]-2H-tetrazolium) assay

Proliferation of cancer cells isolated from MMTV-PyMT;Ccr2−/− and MMTV-PyMT;Ccr2+/− mice was measured using the CellTiter 96 AQueous One Solution Cell Proliferation Assay (MTS; Promega) according to the manufacturer’s instructions. In this assay, the MTS tetrazolium compound (Owen’s reagent) was bioreduced by metabolically active cells into a colored formazan product. The quantity of formazan product was measured in a 96-well plate by absorbance at 490 nm.

RNA in situ hybridization (ISH)

RNA ISH was performed on PFA-fixed paraffin-embedded tissue sections using an RNAscope Chromogenic 2.0 Detection Kit (Advanced Cell Diagnostics [ACD], Inc.). A Ccr2 probe was custom designed by ACD, Inc. (#436261-C2) and used according to
the manufacturer’s instructions. We confirmed that no signal was found with the probe using Ccr2−/− tissues. RNA FISH for Ccr2, Krt8, Cd8a, and Ifn-g was performed on fresh frozen tissue sections using an RNAscope Fluorescent Multiplex Assay Kit (ACD, Inc.) with the following probes (by ACD, Inc.): Ccr2: 436261-C2; Krt18: 424531-C1; Cd8a: 401681-C1; and Ifn-g: 311391-C3. They were used according to the manufacturer’s instructions. For Ccr2 RNA FISH, we confirmed that no signal was found with the probe using Ccr2+/− tissues.

H&E staining

PFA-fixed paraffin-embedded tissue sections were deparaffinized and rehydrated following standard protocols, stained with Gill’s Hematoxylin (REF6765008; Thermo Fisher Scientific) for 3 min, washed in tap water; rinsed with Nu-Clear II (REF6769009; Thermo Fisher Scientific), and then rinsed again first with tap water and then with Bluing Reagent (REF 6769001; Thermo Fisher Scientific). Slides were then stained with eosin (HT110180; Sigma-Aldrich), dehydrated following standard protocols, air-dried, and mounted with Cytoseal 60 (#931016; Thermo Fisher Scientific).

Immunofluorescence staining

To stain for cytokeratin 5 and cytokeratin 8, paraffin sections were deparaffinized and rehydrated, and antigen retrieval was performed by boiling slides in Tris EDTA buffer (10 mM Tris base and 1 mM EDTA, pH 9.0) for 6 min in a pressure cooker. The slides were blocked with 1× blocking buffer (PBS containing 2.5% BSA and 5% goat serum) and Fc receptor blocker. Sections were incubated with rabbit anti-CD3 polyclonal antibody (1:500 dilution; Abcam), rat anti-Cd8a (Clone 5.3; Invitrogen/Biosciences) – Alexa Fluor 488 conjugated antibody (ab193894; 1:200 dilution; Abcam) and anti-Cytoseal 60 (#831016; Thermo Fisher Scientific).

For all other stainings, frozen tissue sections were incubated with 1× blocking buffer (5% goat serum and 2.5% BSA in PBS) and Fc receptor blocker. Sections were incubated with rabbit anti-CD3 polyclonal antibody (Clone ER-HR2S, 1:100 dilution; Abcam), rat anti-MHC class I monoclonal antibody (Clone CR-ER52, 1:100 dilution; Abcam), rat anti-CD3 polyclonal antibody (5C5; 1:100 dilution; Abcam), rat anti-PyMT antibody (Ab15085, 1:200 dilution; Abcam), rabbit anti-cleaved caspase-3 (Asp175; D3E9; #9579; 1:200 dilution; Cell Signaling Technology), or rabbit anti-phospho-STAT3 (1:500 dilution; Cell Signaling Technology). After incubating with secondary biotinylated goat anti-rabbit IgG antibody (1:500 dilution; BA-1000; Vector Laboratories) for 1 h at room temperature, slides were incubated with avidin-conjugated horseradish peroxidase (PK-6100; Vector Laboratories) for 30 min, and the signals were detected by a 3,3′-diaminobenzidine substrate kit (SK-4100; Vector Laboratories).

Lastly, sections were counterstained with hematoxylin. TUNEL staining was performed on deparaffinized sections to detect late-stage apoptotic cells using the ApopTag peroxidase in situ apoptosis detection kit (Millipore) according to the manufacturer’s instructions. Images were scanned by an Aperio ScanScope CS System (Leica Biosystems), and positive nuclei were counted using Aperio eSlide Capture Devices software (Leica Biosystems).

Immunoseq

Tumors from Ccr2+/+ and Ccr2−/− transplants were isolated and immediately placed in liquid nitrogen for shipment. Amplification and sequencing were performed on the immunoseq platform (Adaptive Biotechnologies) using a multiplex PCR-based assay that exclusively targets rearranged TCR genes. Sequencing data were analyzed using immunoSEQ Analyzer software. Shannon’s Entropy (H), a measure of the richness and uniformity of the frequency of clones. To account for variation in sequencing depth, entropy was normalized by its maximum value (Hmax):

\[ H = -\sum_{i=1}^{N} p_i \log_2 p_i, \]

where N equals the number of unique clones and pi the frequency of clones. To account for variation in sequencing depth, entropy was normalized by its maximum value (Hmax):

\[ H_n = H / H_{\text{max}}. \]

Clonality is defined as C = 1 − Hn (Sherwood et al., 2013). Sequencing files are available from the immunoSEQ website through accession DOI 10.21417/MF2020JEM.

Transcriptional profiling and bioinformatics analysis

CCR2+/+ or Ccr2−/− cancer cells were isolated from tumors and sorted as EpCAM−/CD45−/CD31+ live cells (using 7-AAD Viability Staining Solution; Thermo Fisher Scientific) 4 wk after orthotopic transplantation into the mammary glands of wild-type C57BL/6 mice. Total cancer cell RNA was extracted using a
Cytotoxic CD8+ T cells were isolated from spleens of OT-I mice using magnetic labeling and separation (Miltenyi Biotec). Briefly, the spleen was forced through a 100-µm cell strainer, and flow-through cells were collected. After red blood cells were lysed, the splenocytes were washed and incubated with CD8α+ T Cell Biotin-antibody Cocktail, mouse (Miltenyi Biotec) at 4°C for 5 min, followed by incubating with anti-biotin microbeads (Miltenyi Biotec) at 4°C for 10 min. The cell suspension was applied to an LS column (Miltenyi Biotec) in a magnetic field, and the flow-through (negatively selected) CD8+ T cells were collected. The isolated CD8+ T cells were cultured on plates coated with anti-mouse-CD3 (BioLegend) in RPMI-1640 containing 10% FBS, 50 µM of β-mercaptoethanol, 20 ng/ml mouse interleukin-2, 2 ng/ml mouse interleukin-7, and 1% penicillin/streptomycin for 6–9 d. Primary cancer cells were isolated as described above from MMTV-PyMT-chOVA;Ccr2−/− or MMTV-PyMT-chOVA;Ccr2+/− mice and cultured overnight with or without CCR2 antagonist (10 µM; RS504393) and OVA peptides (1 µg/ml) in DMEM/F12 medium with 10% FBS. The E0771 cancer cell line was infected with lentivirus expressing luciferase and OVA SIINFEKL peptide fused to the C-terminus of enhanced GFP. Transduced cells were sorted by flow cytometry for enhanced GFP-positive cells. For chromium (51Cr) release assay, cancer cells (1,000 per well) were incubated with 50 µl of 51Cr solution (activity 1 mCi/ml; PerkinElmer) plus 50 µl of RPMI medium with 10% FBS for 2 h at 37°C. After the cells were rinsed three times with RPMI plus 10% FBS, 50 µl of cancer cells (1,000) were plated into each well of a 96-well V-bottom plate, followed by the addition of 50 µl of CD8+ T cells at a ratio of 10:1. After 4 h of incubation at 37°C, 50 µl of supernatant from each well was transferred to miniature vials, and radioactivity was determined by a Beckman scintillation counter (PerkinElmer). The percentage of specific lysis was calculated using the standard formula [(experimental – spontaneous release)/(total – spontaneous release) × 100] and expressed as the mean of triplicate samples.

Western blot
Snap-frozen tumor samples were homogenized in radio immunoprecipitation assay buffer with eComplete Protease Inhibitor Cocktail Tablets (Roche) and phosphatase inhibitor cocktail (Thermo Fisher Scientific), and lysis was performed on ice for 30 min. Cell lysates were centrifuged for 15 min at 12,000 ×g at 4°C. After centrifugation, the supernatant was mixed with 4× loading buffer plus 2.5% of β-mercaptoethanol and loaded on 8% SDS/PAGE gels. Proteins with similar molecular weight were detected using blots from separate gels loaded with an equal amount of samples. Protein bands were transferred to polyvinylidene difluoride membranes (Bio-Rad) at 90 V for 2 h in a Bio-Rad Mini Trans-Blot system. The membrane was incubated sequentially with different primary antibodies: anti-p65, anti-p-p65, anti-p-STAT1, anti-p-STAT3, and anti-STAT3 (all from Cell Signaling Technology) and anti-STAT1 and anti-β-Actin (Santa Cruz Biotechnology). Secondary antibodies were from LI-COR. Protein detection was performed using the Odyssey imaging system (LI-COR).

Whole-mount carmine staining of mammary glands
Mammary glands were isolated and spread out on glass slides. Then, the mammary glands were fixed in Carnoy’s fixative (60% ethanol, 30% chloroform, and 10% glacial acetic acid) for 2–4 h at room temperature, followed by 15-min washes first in 70% and then in 50% ethanol, with a final rinse in double-distilled water. The glands were then stained with carmine red stain (2.5 g of aluminum potassium sulfate, 1 g of carmine, and 1 ml of water to a final volume of 500 ml, and boiled for 25 min) for 16 h or until the fat pad was a uniform pink color. After staining, the mammary glands were de-stained in 1% solution of IN HCl in 70% ethanol.
De-stained glands were rinsed twice for 15 min in 70% ethanol followed by 15-min washes first in 90% and then in 100% ethanol. The mammary glands were then placed in xylene for 2 h for clearing and were mounted.

Statistical analysis
All statistical analyses were performed using GraphPad Prism Version 6 or newer software. Data were analyzed using Kaplan-Meier survival analysis, Student’s t tests, ANOVA, $\chi^2$ test, and log-rank (Mantel-Cox) test, as indicated in the figure legends, with an $\alpha$ of 0.05. For tumor volume analysis, one-way ANOVA followed by Sidak’s multiple comparisons test; Welch’s ANOVA followed by Dunnett’s T3 multiple comparisons test; or Student’s t tests were performed as indicated in the legends. The number of sampled units, n, is indicated in the figure legends.

Online supplemental material
Fig. S1 (related to Fig. 1) shows CCR2 expression in spontaneous MMTV-PyMT tumors and lungs. Fig. S2 shows the flow cytometry gating strategy for immune cells. Fig. S3 (related to Figs. 4 and 5) shows T cell infiltration and depletion in tumors derived from Ccr2$^{+/+}$ or Ccr2$^{-/-}$ cancer cells. Fig. S4 (related to Figs. 8 and 9) shows the activation of T cells and the infiltration of myeloid cell in tumors derived from Ccr2$^{+/+}$ or Ccr2$^{-/-}$ cancer cells. Fig. S5 (related to Fig. 10) shows cytokine analysis in tumor lysate and conditioned medium.

Acknowledgments
We thank Laura Maiorino for drawing the included illustrations. This work was supported by funds from the CSHL Cancer Center (P30-CA045508) and the Department of Defense (W81XWH-14-1-0078) to M. Egeblad; from the Charles and Marie Robertson Foundation to X.-Y. He; from the Lustgarten Foundation and the V Foundation for Cancer Research to C.O. dos Santos; and from the Lustgarten Foundation, the National Cancer Institute, and the Cedar Hill Marie Robertson Foundation to X.-Y. He; from the Lustgarten Foundation. Support was also provided by the State of New York H. Anderson Fellow. M. Egeblad, C.O. dos Santos, and L. Van Aelst provided experimental advice. M. R. Fein, J.E. Wilkinson, and A. Pommier provided statistical analysis. M. R. Fein and X.-Y. He performed the animal experiments. M. R. Fein and X.-Y. He designed the experiments. M. R. Fein and C.O. dos Santos designed the flow cytometry gating strategy for immune cells. Fig. S3 (related to Figs. 10) shows the activation of T cells and the infiltration of myeloid cell in tumors derived from Ccr2$^{+/+}$ or Ccr2$^{-/-}$ cancer cells. Fig. S4 (related to Figs. 8 and 9) shows the activation of T cells and the infiltration of myeloid cell in tumors derived from Ccr2$^{+/+}$ or Ccr2$^{-/-}$ cancer cells. Fig. S5 (related to Fig. 10) shows cytokine analysis in tumor lysate and conditioned medium.

CCR2 signaling in cancer cells causes immune evasion

https://doi.org/10.1084/jem.20181551
Figure S1.  CCR2 expression in spontaneous MMTV-PyMT tumors and lungs. (A) Mammary ductal epithelial branching and invasion are similar in Ccr2+/+ and Ccr2−/− mice, as indicated by carmine red staining of inguinal mammary glands at indicated age (left; scale bar = 4 mm) and immunofluorescence staining of basal and luminal cell markers (right; cytokeratin [CK] 5 and CK8, respectively; scale bar = 100 µm). (B) Representative photomicrographs of H&E–stained tumors from MMTV-PyMT; Ccr2+/+, MMTV-PyMT; Ccr2+/−, and MMTV-PyMT; Ccr2−/− mice (scale bar = 1 mm). (C) Histology score of solid area of primary tumors from MMTV-PyMT; Ccr2+/+, MMTV-PyMT; Ccr2+/−, and MMTV-PyMT; Ccr2−/− mice (one-way ANOVA; n = 8 in MMTV-PyMT; Ccr2+/+, n = 11 in MMTV-PyMT; Ccr2+/−, and n = 12 in MMTV-PyMT; Ccr2−/−). (D) Left: Representative RNA FISH on MMTV-PyMT; Ccr2+/+ tumors showing that Ccr2 mRNA (green) is expressed by Krt18-positive (red) cancer cells. Right: No Ccr2 expression is detected in MMTV-PyMT; Ccr2−/− tumors. Scale bar = 20 µm. (E) Purity of cancer cells is >90% after cell isolation, as determined by flow cytometry for EpCAM (black; a marker expressed on epithelial-derived MMTV-PyMT cells) compared with background (gray). Representative of three separate isolations. (F) mRNA was collected from MMTV-PyMT; Ccr2+/+, MMTV-PyMT; Ccr2+/−, and MMTV-PyMT; Ccr2−/− tumor cells, and qPCR was performed for Ccr2 and normalized to β-actin expression (one-way ANOVA; n = 3). (G) Tumors from Ccr2+/− cancer cells phenocopy those from Ccr2−/− cancer cells, regardless of whether the host is Ccr2+/+ or Ccr2−/−. Tumor burden was determined by weekly caliper measurements (one-way ANOVA followed by Sidak’s multiple comparisons test at the end time point; n = 8 for all conditions). (H) Metastatic burden is unchanged in MMTV-PyMT; Ccr2+/+, MMTV-PyMT; Ccr2+/−, and MMTV-PyMT; Ccr2−/− mice, as determined by quantification from H&E–stained lung sections, indicated as percentage of the area of the lung tissues (one-way ANOVA; n = 24 MMTV-PyMT; Ccr2+/+, 33 MMTV-PyMT; Ccr2+/−, and 27 MMTV-PyMT; Ccr2−/− mice). (I) The number of metastatic foci is unchanged in MMTV-PyMT; Ccr2+/+, MMTV-PyMT; Ccr2+/−, and MMTV-PyMT; Ccr2−/− mice. Mice were classified as having either ≤0.1 foci/mm² lung area (χ² test; n = 24 MMTV-PyMT; Ccr2+/+, 33 MMTV-PyMT; Ccr2+/−, and 27 MMTV-PyMT; Ccr2−/− mice). (J) The average size of the metastatic foci is decreased in MMTV-PyMT; Ccr2+/− and MMTV-PyMT; Ccr2−/− mice compared with foci in MMTV-PyMT; Ccr2+/+ mice. The number of mice with an average of large versus small metastatic foci is indicated (χ² test; n = 24 MMTV-PyMT; Ccr2+/+, 33 MMTV-PyMT; Ccr2+/−, and 27 MMTV-PyMT; Ccr2−/− mice). Means ± SEM are indicated. P values were determined by the tests indicated. *, P < 0.05; **, P < 0.01; ***, P < 0.001. N.S., nonsignificant.
Figure S2. **Gating strategy for immune cells.** For flow cytometry analysis, single cells from tumors were gated on live CD45+ cells and were further analyzed using the indicated markers to characterize infiltration of tumor-associated macrophages (TAMs), DCs, T cells, granulocytes, monocytes, and MDSCs. SSC, side scatter; gMDSC, granulocytic myeloid-derived suppressor cell; mMDSC, monocytic myeloid-derived suppressor cell.
Figure S3. **T cell infiltration in tumors derived from Ccr2^{+/+} or Ccr2^{−/−} cancer cells.** (A) There is no difference between Ccr2^{+/+} and Ccr2^{−/−} tumors during the growth-restricted phase in the percentage of CD3^{+} T cells among CD45^{+} leukocytes, as determined by flow cytometry for CD45^{+}CD3^{+} cells (n = 5). (B) FoxP3^{+}CD4^{+} regulatory T cell infiltration is increased in Ccr2^{+/+} tumors compared with Ccr2^{−/−} tumors during the growth-restricted phase, as determined by flow cytometry gated on CD45^{+}CD3^{+}CD4^{+} cells (n = 5). (C) Depletion of CD8^{+} T cells with anti-CD8a antibody significantly accelerated the growth of tumors from Ccr2^{−/−} cancer cells (arrows indicate treatment with antibody; n = 5 for all conditions). (D) Pharmacological inhibition of CCR2 increased OT-1 T cell cytotoxicity toward E0771 cancer cells expressing OVA peptide, as measured by chromium (Cr51) release (each dot is a triplicate from the same experiment, and similar results were obtained in an independently performed experiment). (E) Immune suppression induced by cancer cell CCR2 signaling is confined to the local tumor microenvironment. Ccr2^{+/+} cancer cells transplanted into one mammary gland did not alter the growth of tumors from Ccr2^{−/−} cancer cells transplanted to the contralateral gland. Means ± SEM are indicated. P values were determined by Student’s t test (A, B, and D). Tumor burden was determined by weekly caliper measurements (n = 10 for all conditions). Tumor volume was analyzed at the end time point by one-way ANOVA, followed by Sidak’s multiple comparisons test (C) or by Welch’s ANOVA followed by Dunnett’s T3 multiple comparisons test (due to unequal variances; E). *, P < 0.05; **, P < 0.01. N.S., nonsignificant.
Figure S4. **Myeloid cell infiltration in tumors derived from Ccr2\(^{+/+}\) or Ccr2\(^{-/-}\) cancer cells.** (A) Tumors from transplanted Ccr2\(^{-/-}\) cancer cells have elevated markers of T cell infiltration and activation, including Cd8\(^{+}\), Ifn-g, and Cxcl9 mRNA, compared with tumors from Ccr2\(^{+/+}\) cancer cells. RT-qPCR was performed on tumors from transplants of Ccr2\(^{+/+}\) and Ccr2\(^{-/-}\) cancer cells isolated during the growth-restricted phase (\(n = 5\) or 6 for Ccr2\(^{+/+}\) tumors, and \(n = 6\)–8 for Ccr2\(^{-/-}\) tumors). (B) Representative RNA FISH for Ifn-g (green) and Cd8a (red) probes in the early phase (3 wk; upper panels) and the late, growth-restricted phase (5–6 wk; bottom panels) of tumors from Ccr2\(^{+/+}\) and Ccr2\(^{-/-}\) transplanted cancer cells. Nuclei are counterstained with DAPI (blue; scale bar = 20 \(\mu\)m). (C and D) Quantification of RNA FISH shows more Ifn-g–expressing Cd8\(^{+}\) T cells in tumors from Ccr2\(^{-/-}\) cancer cells compared with Ccr2\(^{+/+}\) cancer cells at both early (C) and late, growth-restricted (D) phases (each dot represents the average of three to eight random fields of views of one tumor; \(n = 5\) tumors for early phase; \(n = 7\) or 8 tumors for late, growth-restricted phase). (E) Macrophage infiltration is unchanged between Ccr2\(^{+/+}\) and Ccr2\(^{-/-}\) tumors during the growth-restricted phase, as determined by flow cytometry gated on CD45\(^{+}\)CD11b\(^{+}\)MHC class II\(^{+}\)F4/80\(^{+}\) cells (\(n = 5\) and 4 for Ccr2\(^{+/+}\) and Ccr2\(^{-/-}\) tumors, respectively). (F) Percentage of CD11b\(^{+}\)MHC class II\(^{+}\) cells is reduced in Ccr2\(^{-/-}\) tumors compared with Ccr2\(^{+/+}\) tumors during the growth-restricted phase, as determined by flow cytometry gated on CD45\(^{+}\) cells (\(n = 5\) and 4 for Ccr2\(^{+/+}\) and Ccr2\(^{-/-}\) tumors, respectively). (G) Granulocytes and granulocytic MDSCs are decreased on Ccr2\(^{-/-}\) tumors during the growth-restricted phase, as determined by flow cytometry gated on CD45\(^{+}\)CD11b\(^{+}\)CD11c\(^{-}\)Ly6G\(^{-}\)Ly6C\(^{-}\) cells (\(n = 5\)). (H) Inflammatory monocytes and monocyctic MDSCs are increased on Ccr2\(^{-/-}\) tumors during the growth-restricted phase, as determined by flow cytometry gated on CD45\(^{+}\)CD11b\(^{+}\)CD11c\(^{-}\)Ly6G\(^{-}\)Ly6C\(^{-}\) cells (\(n = 5\)). (I) CD103\(^{+}\) DCs are increased in MMTV-PyMT;Ccr2\(^{-/-}\) tumors compared with MMTV-PyMT;Ccr2\(^{+/+}\) tumors during the growth-restricted phase, as determined by flow cytometry gated on CD11c\(^{+}\)MHCII\(^{+}\) cells within the CD45\(^{+}\) population (\(n = 4\) and 5 for MMTV-PyMT;Ccr2\(^{+/+}\) and MMTV-PyMT;Ccr2\(^{-/-}\) tumors, respectively). Means ± SEM are indicated. P values were determined by Student’s t test. *, \(P < 0.05\); **, \(P < 0.01\); ***, \(P < 0.001\). N.S., nonsignificant.
Figure S5. Cytokine analysis in tumor lysate and conditioned medium. (A) Cytokine analysis from MMTV-PyMT;Ccr2^{+/+} and MMTV-PyMT;Ccr2^{-/-} tumors during growth-restricted phase, using the Proteome Profiler Mouse Cytokine Array Kit, Panel A (n = 4). (B) Cytokine analysis from supernatant of MMTV-PyMT;Ccr2^{+/+} and MMTV-PyMT;Ccr2^{-/-} cancer cells isolated during growth-restricted phase, using the Proteome Profiler Mouse Cytokine Array Kit, Panel A after serum starvation for 24 h (n = 4). Means ± SEM are indicated. P values were determined by multiple Student’s t tests. *, P < 0.05.
