Abstract

Background: Testicular tumor is one of the common solid tumors in young men. Testicular choriocarcinoma is a non spermatogonial germ cell tumor, which is the most rare of all testicular cancers. Choriocarcinoma usually shows bleeding at the metastatic site, while gastrointestinal involvement is rare.

Methods: Here we report a case of testicular choriocarcinoma with gastrointestinal bleeding as the first diagnosis, and summarize the similar cases all over the world in recent 20 years.

Results: A 28 year old male was treated with repeated black stools for 2 months. No bleeding foci of stomach, duodenum, colon and rectum were found in endoscopy, and no bleeding foci of digestive tract were found in selective angiography, but space occupying lesions of lung, liver and upper jejunum were found in chest and abdominal CT, Considering the possibility of metastatic tumor and the ineffectiveness of medical treatment, the patient was converted to surgical treatment. The postoperative pathology was consistent with testicular choriocarcinoma. The patient received a chemotherapy regimen of paclitaxel, ifosfamide and cisplatin. At present, the chemotherapy regimen is well tolerated.

Conclusions: The case report confirmed that even if we can't find the logical relationship between clinical manifestations and genital examination, genital examination should also be part of the patient's systematic examination.

Introduction

Gastrointestinal bleeding has many clinical manifestations, including hematemesis, black stool and hematochezia, and its common causes include peptic ulcer bleeding, esophageal and gastric variceal bleeding, gastrointestinal primary tumor bleeding and biliary tract bleeding, but bleeding caused by extragastrointestinal tumor metastasis to the digestive tract is very rare in clinic, Especially, bleeding caused by testicular choriocarcinoma metastasis to the gastrointestinal tract is more rare. In 1983, Teryn et al.\cite{1} Described the first case of jejunal bleeding caused by metastatic testicular choriocarcinoma. This paper summarizes clinical data of a patient with metastatic choriocarcinoma with gastrointestinal bleeding as the clinical manifestation in the First Affiliated Hospital of Sun Yat sen University, combined with the review of relevant literature in the past 20 years, so as to improve the diagnostic rate of the etiology of gastrointestinal bleeding and reduce misdiagnosis and missed diagnosis.

Case Presentation

Clinical data

A 28 year old male patient was admitted to the hospital mainly because of "repeated black defecation for more than 2 months". He denied the history of peptic ulcers, liver cirrhosis and portal hypertension. One year ago, he underwent a CT examination of his chest, upper and lower abdomen and basin due to "right testicular swelling". The results showed that there was a huge tumor on the right testicle with clear
boundary and protruding into the inguinal canal, about 91mm×86mm×119 mm in size(FIGURE 1), uneven density, medium enhancement in enhanced scanning. The left testicle is located in the inguinal canal. Imaging diagnosis: right testicular mass, considering the possibility of seminoma. Left cryptorchidism. No obvious lesions were found in the chest and abdomen. Improve the examination of tumor markers: AFP 86.57ng/ml, HCG 11439 mIU/ml. "Radical resection of the right testis" was performed. The postoperative pathology showed that some tumor cells in testicular tissue were nest like, adenoid or sieve reticular distribution, rich cytoplasm, large nucleus and obvious nucleolus. Syncytial cells were seen with massive bleeding; In addition, squamous epithelium, glandular epithelium, cartilage and small glandular tubular structure can be seen. The morphology is consistent with a malignant mixed germ cell tumor. It is suggested to add immunohistochemical detection to assist in the diagnosis. However, the patient did not undergo immunohistochemical detection, and did not undergo any follow-up treatment such as chemotherapy or radiotherapy. Physical examination after admission: poor spirit, severe anemia, pale eyelid conjunctiva, lips and nail bed, no obvious abnormalities in physical examination such as cardiopulmonary examination. Improve relevant laboratory tests after admission: HB 38g/L, normal cell anemia; Albumin, liver and kidney function and coagulation function were normal.

**Diagnosis and treatment process**

After admission, the gastroscopy was urgently improved. Gastroscopy showed that there was no bleeding focus in the stomach and duodenum; Colonoscopy showed that a large number of black feces and fecal water were seen in the intestinal cavity, no bright red blood was found, and no bleeding focus was found in the terminal ileum, ileocecal valve, cecum, appendix opening, colon and rectal mucosa(FIGURE 2); Improve selective angiography, see intrahepatic multiple tumor staining, not excluding the possibility of multiple liver metastases, but no clear gastrointestinal bleeding focus has been found.Perfect CT examination of chest and whole abdomen showed that there was a mass in the tongue segment of the upper lobe of the left lung, considering metastasis, and a nodule in the anterior basal segment of the lower lobe of the right lung, considering the possibility of metastasis; Abnormal enhancement of local intestinal tract in the upper jejunum did not rule out angiogenic lesions(FIGURE 3). After medical treatment, the symptoms of black stool were relieved and the hemoglobin increased to 87g/L.

The patient began to eat cold fluid on the 5th day after stopping defecation, but the symptoms of defecation occurred again on the 3rd day. The volume was about 1000ml, blood pressure decreased to 69/44mmhg, and the hemoglobin was about 59g/L, so he was given emergency laparotomy, jejunectomy and ileal diverticulectomy. It can be seen during operation: about 15 cm away from treiz ligament, the upper end of jejunum can be overlapped, and soft masses can be touched. Black intestinal fluid accumulates in this segment of the intestinal cavity. Combined with preoperative CT images, it is considered that the masses here are bleeding sites. Resection of jejunal tumor: the mesentery of the small intestine supplying the tumor segment was ligated and cut off during the operation, with length of about 5cm(FIGURE 4). Postoperative pathology showed that: (small intestine) there was tumor infiltration in the intestinal septum with massive bleeding. The tumor cells showed two forms, one was a rich and bright cytoplasm with a clear boundary, and the other was a multinucleated syncytial cell like; The tumor
cells are heterotypic, with mitotic images and focal necrosis (FIGURE 5). Immunohistochemistry showed: cancer cells CK7 (+), HCG diffuse (+), AFP weak (+), p57 part (+), p53 part (+), CD17 individual cells (+), PLAP focal (+), CD56 individual cells (+), CK20 (-), CDX-2 (-), SATB (-), TTF-1 (-), napsina (-), p40 (-), Sall4 (-), OCT3 / 4 (-), CD30 (-), syn (-). It is considered to be intestinal metastasis of malignant germ cell tumor, and the metastatic component is mainly choriocarcinoma. The patient stopped bleeding after the operation and is currently receiving further chemotherapy. The chemotherapy regimen is tip (paclitaxel, ifosfamide and cisplatin). At present, the patient tolerated the chemotherapy regimen well and was discharged for outpatient follow-up. During the one month follow-up, the patient showed no signs of recurrent gastrointestinal bleeding.

**Literature Review**

16 cases reported in other journals in the past 20 years were reviewed and analyzed (Table 1). We found that the age of the patients ranged from 17 to 60 years old. Most of them had melena as the first diagnosis symptom (12/16, 75%), and a few had anemia as the first diagnosis symptom (3/16, 18.75%). Only one patient had hematemesis as the first diagnosis symptom, which may be related to the fact that most of the bleeding sites were in the small intestine (10/16, 62.5%), of which duodenal bleeding was the most, with 6 cases. There were only 4 patients with gastric bleeding alone, and 2 patients with bleeding in stomach and colon. Almost all patients received chemotherapy, 6 patients received surgical treatment, but only 1 patient survived (survival rate 16.7%), while 5 patients survived (50%) in 10 patients who received chemotherapy only without surgery. This result may be related to the fact that patients undergoing surgery generally have a large amount of bleeding and serious condition, and surgical intervention must be taken.
| Case | Year | Age | Symptom | Position of bleeding | Treatment | Ending |
|------|------|-----|---------|----------------------|-----------|--------|
| 1[2] | 2002 | 60  | anemia  | jejunum              | surgical operation  | death   |
| 2[3] | 2004 | 28  | haematemesis | stomach              | chemotherapy | death   |
| 3[4] | 2004 | 37  | anemia  | Stomach and colon    | chemotherapy | death   |
| 4[5] | 2005 | 51  | melena  | Stomach and colon    | surgical operation+chemotherapy | death   |
| 5[6] | 2009 | 24  | melena  | Intestinum tenue     | surgical operation+chemotherapy | live    |
| 6[7] | 2010 | 17  | melena  | duodenum             | chemotherapy | live    |
| 7[8] | 2011 | 25  | melena  | stomach              | -          | death   |
| 8[9] | 2012 | 24  | melena  | duodenum             | chemotherapy | death   |
| 9[10]| 2013 | 24  | melena  | duodenum             | chemotherapy | live    |
| 10[11]| 2013| 20  | anemia  | stomach              | surgical operation+chemotherapy | death   |
| 11[12]| 2015| 18  | melena  | stomach              | chemotherapy | live    |
| 12[13]| 2019| 30  | melena  | duodenum             | chemotherapy | death   |
| 13[14]| 2020| 17  | melena  | duodenum             | chemotherapy | live    |
| 14[15]| 2021| 32  | melena  | jejunum              | surgical operation+chemotherapy | death   |
| 15[16]| 2021| 33  | melena  | Intestinum tenue     | surgical operation+chemotherapy | death   |
| 16[17]| 2021| 40  | melena  | duodenum             | chemotherapy | live    |

Death refers to death during hospitalization

**Discussion**

Testicular cancer is the most common tumor in men aged 15 to 44[18,19], which is generally divided into germ cell tumors and non germ cell tumors. Germ cell tumors include several cell types, roughly divided into seminoma and non seminoma. Among them, choriocarcinoma is a non seminoma germ cell tumor,
which is the most rare, accounting for 1% - 3% of all testicular tumors \cite{20}. At present, the cause of
testicular choriocarcinoma is not clear, which may be related to a variety of risk factors. Cryptorchidism
can be one of the important factors leading to testicular choriocarcinoma. It is reported that the
probability of cryptorchidism patients with choriocarcinoma is 20-40 times higher than that of normal
testis \cite{21} in this paper, the patient is left cryptorchidism, which may be one of the important factors
leading to testicular choriocarcinoma.

Choriocarcinoma mainly metastasizes through blood. Because of its strong invasiveness to blood
vessels and tissues, it leads to tissue bleeding and necrosis. Metastasis occurs early and widely.
Therefore, when choriocarcinoma is diagnosed, a large number of cases have metastasized, so that most
of the initial manifestations are metastasis related symptoms \cite{22}. Because the most common metastatic
sites are lung, liver and brain \cite{23}, patients usually show seizures, stroke like symptoms, blurred
consciousness and-or hemoptysis. Gastrointestinal metastasis of choriocarcinoma is very rare.
Gastrointestinal metastasis occurs in 5% of germ cell tumors. Gastrointestinal metastasis is considered
to be the result of direct diffusion or hematogenous diffusion from adjacent retroperitoneal lymph nodes,
and direct infiltration is more common than hematogenous diffusion. The small intestine, the most
common duodenum, is the most common metastatic site (72%), followed by the esophagus, stomach
and colon \cite{6,24}. The involvement of the small intestine is characterized by intestinal obstruction or
gastrointestinal bleeding, usually abdominal pain, black stool or anemia. In this paper, the patient was
treated with repeated black stool as the first symptom, but in the follow-up examination, it was found that
there were tumor metastasis in the lung and liver in addition to small intestinal metastasis, but did not
show clinical symptoms.

The determination of serum tumor markers HCG and AFP may be helpful in the diagnosis of
choriocarcinoma because they are elevated in about 80% of cases. The serum concentration of HCG can
also be used to monitor the response to treatment. According to the international cooperative
organization for germ cell cancer, HCG higher than 50000miu/ml indicates poor prognosis. However, in
this paper, the monitoring of HCG level after radical resection of testicular cancer is ignored, which leads
to multiple metastasis and poor prognosis. In addition, as a transcription factor, GATA3 is another
immune tumor marker sensitive to choriocarcinoma \cite{25}.

The imaging of testicular choriocarcinoma lacks characteristic changes that can be distinguished from
other types of germ cell tumors. It is difficult to diagnose choriocarcinoma first. Most of the specimens
obtained during surgical resection are confirmed by pathology. The typical histopathological feature of
metastatic choriocarcinoma is the coexistence of cytotrophoblast and syncytiotrophoblast cells without
mesenchymal cells, which is different from other germ cell tumors with only scattered
syncytiotrophoblast cells.

The treatment of testicular choriocarcinoma depends on the stage of the disease. Radical orchiectomy
and dissection of affected lymph nodes are the treatment of early diseases. The treatment of bleeding
caued by gastrointestinal metastasis of choriocarcinoma is similar to that of other gastrointestinal
bleeding, including endoscopic intervention, embolization or surgical resection. Abdelkader et al reported a case of bleeding from duodenal choriocarcinoma. The exudation point was ablated by an endoscopic adrenalin injection and argon plasma coagulation system to finally stop bleeding[12]. Bain et al.[7] Reported a case of bleeding treated by angiography and embolization. Iglesias et al. [26] Used surgical hemostasis after endoscopic injection of adrenalin and argon plasma coagulation system ablation failure. In this paper, because there was no bleeding focus under endoscopy and selective angiography, the patient finally stopped bleeding by surgical means.

Chemotherapy consolidation is usually required after bleeding stops. For metastatic choriocarcinoma, platinum therapy is recommended as the first-line chemotherapy, but unfortunately, choriocarcinoma is not so sensitive to chemotherapy. Most patients' tumors progress so rapidly that they do not respond to the standard chemotherapy regimen of three to four cycles of BEP (bleomycin, etoposide and cisplatin)[27]. In recurrent cases, salvage chemotherapy with vincristine and ifosfamide may help to reduce the tumor burden, but these patients may finally have to choose palliative treatment. Simple testicular choriocarcinoma usually has a poor prognosis, with a five-year survival rate of less than 80%.[20]. In some reports, the long-term survival rate is even lower [28, 29], while mixed choriocarcinoma is slightly better. In this paper, the patient was treated with paclitaxel, ifosfamide and cisplatin.

Testicular choriocarcinoma is a rare tumor with strong invasiveness and rapid growth in young men. It mainly metastasizes to the lung, liver and brain. Reports of metastasis to the gastrointestinal tract are rare, which makes it easy to ignore the existence of the disease in the clinical diagnosis and treatment of gastrointestinal bleeding. Therefore, we recommend a more detailed inquiry into medical history and systematic examination. It is very important for us to correctly distinguish and diagnose the etiology of gastrointestinal bleeding. The lack of accurate physical examination and laboratory examination will lead to waste of patients' diagnosis and treatment time, the increase of mortality, the extension of hospital stay, and the increase of patients' medical expenses. Therefore, for any young male patient, the most basic reproductive system examination is very important. Among the patients in this article, the reproductive system examination was omitted during the patient's repeated hospitalization outside the hospital, and it was not carried out when he was admitted to our hospital. In addition, the detection of HCG was also omitted. Although the final surgical pathology guided us to diagnose testicular choriocarcinoma, during the process, the patient once had hemorrhagic shock, which may have been life-threatening, and we don't know how many patients died because their doctors missed this article.

Conclusion

Testicular choriocarcinoma is a rare malignant tumor with early metastasis. Although it is extremely rare, gastrointestinal metastasis of choriocarcinoma should be a part of the differential diagnosis of upper gastrointestinal bleeding in young male patients. The earlier we diagnose the disease, the greater the opportunity for us to start treatment in the golden age, and the mortality, hospital stay and treatment cost will be greatly reduced.
Abbreviations

CT: Computed tomography
AFP: Alpha fetoprotein
HCG: Human chorionic gonadotropin
CK: Cytokeratin
