Abstract

Early work extending the Kohn-Sham theory to excited states was based on replacing the study of the ground-state energy as a functional of the ground-state density by a study of an ensemble average of the Hamiltonian as a functional of the corresponding average density. We suggest and develop an alternative to this description of excited states that utilizes the matrix of the density operator taken between any two states of the included space. Such an approach provides more detailed information about the states included, for example, transition probabilities between discrete states of local one-body operators. The new theory is also based on a variational principle for the trace of the Hamiltonian over the space of states that we wish to describe viewed, however, as a functional of the associated array of matrix elements of the density. It finds expression in a matrix version of Kohn-Sham theory. To illustrate the formalism, we study a suitably defined weak-coupling limit, which is our equivalent of the linear response approximation. On this basis, we derive an eigenvalue equation that has the same form as an equation derived directly from the time-dependent Kohn-Sham equation and applied recently with considerable success to molecular excitations. We provide an independent proof, within the defined approximations, that the eigenvalues can be interpreted as true excitation energies,

I. INTRODUCTION

Density functional theory (DFT) was designed originally as a theory of the ground-state of a many-particle system [1–3]. For an extension to include the calculation of excitation energies, several lines of thought have been developed. The earliest was based on a minimum principle [4,5] for the trace of the Hamiltonian over a set of the lowest-energy eigenstates of the system. This theory has been extended to a suitably weighted sum over the same set of eigenstates [6]. The expanded version of the Hohenberg-Kohn theorem, in either case, is that the average energy is a unique functional of the corresponding average density. Excitation energies are (essentially) obtained by taking differences between averages over almost overlapping sets. This approach has not been developed beyond the cited work.

Recently, considerable attention has been focused on the development of other methods for studying excitation energies. One approach is based on time-dependent density functional theory (TDDFT) [9–14]. Here one studies the linear response of the time-dependent density to a time-dependent external field. The Fourier transform of the susceptibility (density-density correlation function), which is the essential ingredient for the calculation of dynamic polarizabilities, has poles at the true eigenstates of the system.

From these elements two different formalisms for the calculation of energies and polarizabilities have been derived, termed density based and density-matrix based coupled Kohn-Sham schemes (CKS) in a recent publication [15]. Both methods have been applied successfully, the density method in [10,14], the density matrix method more extensively in [14–21]. The mathematical equivalence of the two formalisms derived from TDDFT has been established in Ref. [15], so that it is only a matter of numerical convenience which one is used in practice. To argue the utility of the formalism developed in this paper, we shall show that in a suitable approximation it yields the eigenvalue equation of the density-matrix CKS scheme. It also permits the calculation of electromagnetic transition rates between the excited states studied and the ground state without the explicit use of wave functions.

We also call attention to several recent studies of the excited state problem that involve extensions of the variationally based KS theory to individual excited states [22,23]. For these methods, as well, successful applications have been made to simple systems. Improved exchange and correlation kernels necessary for all these methods and a connection with many-body perturbation theory are discussed in [24], whereas in [25] an exchange-correlation potential is suggested to provide more accurate continuum KS orbitals needed for excited state and polarizability calculations.

In this paper, we return to a study of the trace variational principle [26–28]. Instead of considering the average energy as a functional of the average density, however, we argue for the introduction of a matrix array of densities, i. e., all matrix elements of the density operator among all states of a chosen ensemble, and for an investigation of the average energy as a functional of this matrix array. In Sec. II we present arguments to indicate how the Hohenberg-Kohn (HK) analysis can be extended to this case yielding a variational equation for the matrix. We subsequently (Sec. III) generalize the KS analysis, deriving a matrix Kohn-Sham equation (MKS), that contains not only the expected ingredient, a matrix effective potential, but also a matrix of Lagrange multipliers arising from number conservation in each state of the chosen subset; this matrix can be diagonalized, but not otherwise transformed away. By combining solutions of the MKS equations, we can construct
the density array.

As an application of this theory, we study, in Sec. IV, the MKS equations in the weak-coupling limit, which is the equivalent, in our approach, to linear response theory. In this limit, we include only the ground state and excited states characterized (largely) by one 'quasiparticle-quasihole' excitations of the ground-state. Higher excited states are incorporated via simple assumptions concerning their properties. The major result of this analysis is an eigenvalue equation for the aforementioned Lagrange multipliers (relative to their ground-state value) that has the same form as the eigenvalue equation of the density-matrix based CKS. Assuming that the ground-state KS problem has been solved, the major unknown ingredient in these equations, an exchange-correlation interaction, can be identified with the corresponding quantity utilized in current applications, which in practice require an adiabatic approximation.

Comparison of our result with the existing formalism establishes the identity of the eigenvalues of our equation with excitation energies of the system. These energies can be calculated as well from a difference of adjacent averages of the Hamiltonian. By this means, in Sec. V, we establish within the framework of our formalism the physical meaning of the eigenvalues. In a concluding section, we summarize our considerations.

II. HOHENBERG-KOHN ARGUMENTS

The Hamiltonian is written as
\[ \hat{H} = \hat{T} + \hat{V} + \hat{W} + \hat{Y}, \]  
(2.1)
the sum of the kinetic energy, the electrostatic interaction of the electrons with the nucleus, the Coulomb repulsion of the electrons, and an additional fictitious external source term that will be set to zero for actual calculations. The various terms have the forms (x stands for the space-spin pair \((r, s)\)), in atomic units,
\[ \hat{T} = \int dx \hat{\psi}^\dagger(x)\left(-\frac{1}{2}\nabla^2\right)\hat{\psi}(x) \]
\[ = \int \hat{\psi}^\dagger \hat{\tau} \hat{\psi}, \]  
(2.2)
\[ \hat{V} = \int dx \hat{\psi}^\dagger(x)\hat{\psi}(x)v(r), \]  
(2.3)
\[ \hat{W} = \int dx dx' \frac{1}{|r - r'|} \hat{\psi}^\dagger(x)\hat{\psi}^\dagger(x')\hat{\psi}(x')\hat{\psi}(x), \]  
(2.4)
\[ \hat{Y} = \int dx dx' y(x, x')\hat{\eta}(x, x'), \]  
(2.5)
\[ \hat{\eta} = \hat{\psi}^\dagger(x)\hat{\psi}(x)\hat{\psi}^\dagger(x')\hat{\psi}(x'). \]  
(2.6)
The interaction term \(\hat{Y}\) is a combination of one and two body forces. It serves as a device to establish the dependence of the theory on the extended density defined in Eq. (2.18), but is set equal to zero thereafter. This procedure is akin to the use of an external magnetic field in standard density functional theory in order to exhibit the possible dependence on spin polarization. For the traces of these operators over the ensembles introduced below, we use the same symbols without hats.
In the following we shall base our arguments on the variational principle for the trace of the Hamiltonian over the lowest \( M \) eigenstates of a many body system \[6,8,26,28\]. We consider the case where the \((M+1)st\) state has a higher energy than the \( M \)th state, although this criterion is not absolutely necessary.

Let

\[ S = \{|I\}\} \quad (2.7) \]

be the space of states included \((I = 1...M)\). For any operator \( \hat{O} \), we define the restricted trace

\[ O^{(M)} = \sum_{I=1}^{M} \langle I | \hat{O} | I \rangle, \quad (2.8) \]

where it is convenient in the further development not to divide by \( M \).

We then consider a set of propositions formulated in imitation of the Hohenberg-Kohn (HK) theorem \[1\]:

(i) Every choice of a function \( y(x,x') \) in (2.5) determines an \( M \)-dimensional space \( S \) through the solution of the Schrödinger equation. Two different functions \( y \neq y' \) will yield different \( S \neq S' \), provided \( \hat{Y}[y] \) and \( \hat{Y}[y'] \) differ by more than a diagonal matrix in the space \( S \). To see this, suppose that \( \hat{Y}[y] \) and \( \hat{Y}[y'] \) yield the same space \( S \). From the Schrödinger equations for the state \(|I\rangle\), we obtain by subtraction that

\[ \{\hat{Y}[y] - \hat{Y}[y']\}|I\rangle = (E_I - E'_I)|I\rangle, \quad (2.9) \]

where the \( E's \) are the corresponding eigenvalues. Thus, with \( I' \neq I \),

\[ \langle I'|\hat{Y}[y]|I\rangle = \langle I'|\hat{Y}[y']|I\rangle, \quad (2.10) \]

and

\[ \hat{Y}[y] - \hat{Y}[y'] = \sum_{I=1}^{M} (E_I - E'_I)|I\rangle\langle I|. \quad (2.11) \]

Potentials that satisfy this relation will be considered equivalent.

(ii) \( S \) determines the correlation function \( \eta(x,x') = \sum \langle I|\hat{\eta}(x,x')|I\rangle \). This relationship is single-valued and invertible. This can be proved by an adaptation of the standard HK argument, as we now show. Suppose that

\[ S \rightarrow \eta, \quad S' \neq S \rightarrow \eta'. \quad (2.12) \]

It follows that \( \eta \neq \eta' \). We prove this by using the trace variational principle (valid by construction of the sets, as indicated above) to establish two inequalities,

\[ H_S[y] < H_{S'}[y'] + \int (y - y')\eta', \quad (2.13) \]

\[ H_{S'}[y'] < H_S[y] + \int (y' - y)\eta. \quad (2.14) \]
Here, for example, $H_S[y]$ is the ensemble average of $\hat{H}$ over the set $S$, where it is further emphasized that this average is a functional of $y$. Adding (2.13) and (2.14) and assuming that $\eta = \eta'$, we obtain the usual contradiction

$$H_S[y] + H_{S'}[y'] < H_{S'}[y'] + H_S[y]. \quad (2.15)$$

Thus $S$ is a single-valued functional of $\eta$.

Considering $H$ to be a functional of $\eta$, we write the variational principle in the form

$$\delta H = \int \frac{\delta H}{\delta \eta} \delta \eta = 0. \quad (2.16)$$

We shall not attempt, however, to implement the variational principle in this version. Instead, using completeness, we introduce the relation

$$\eta(x, x') = \sum_{I=1}^{\infty} \sum_{I'=1}^{\infty} \langle I | \hat{\psi}^{\dagger}(x) \hat{\psi}(x') | I' \rangle \times \langle I' | \hat{\psi}^{\dagger}(x') \hat{\psi}(x) | I \rangle. \quad (2.17)$$

As long as $M$ is finite, this sum is asymmetric in the two sets of indices. However our aim is to utilize as variational parameters the quantities

$$n(x)_{II'} = \langle I | \hat{\psi}^{\dagger}(x) \hat{\psi}(x') | I' \rangle \quad \{I, I' \in S\}, \quad (2.18)$$

which constitute the elements of an $M \times M$ square matrix $n$. There are two arguments that can be put forward to satisfy ourselves that we can consider the correlation function $\eta(x, x')$ to be a functional of this more restricted set of matrix elements. The first and more satisfactory one at this stage is to let the number $M$ of states included in the trace become large enough so that either pointwise or in the norm the fractional contribution from pieces connecting $I \leq M$ to $I > M$ is negligible. The second is to ask for the temporary indulgence of the reader, by guaranteeing to show that in any application, these matrix elements can either be ignored or expressed explicitly in terms of those of $n$. We call this a closure approximation. When we turn to the application developed in Secs. IV and V, we shall see, that the accuracy of results obtained there depend on a choice of a closure approximation that is historically tied to linear response theory and the associated random phase approximation, namely the approximate characterization of the simplest excited states as boson excitations.

In consequence of the arguments given above, we replace the variational principle (2.16) by the form

$$\delta H = \int \frac{\delta H}{\delta n} \delta n. \quad (2.19)$$

From Eq. (2.19) we can derive a variational equation by imposing the number conservation constraints. If $N$ is the number of electrons, we have

$$\int dx n(x)_{II'} = N \delta_{II'}. \quad (2.20)$$
Introducing a set of Lagrange multipliers $\mu_{II'}$, we now write

$$\delta H - \mu_{II'} \int \delta n(x)_{I'I} = 0,$$

and conclude that

$$\frac{\delta H}{\delta n(x)_{I'I}} = \mu_{II'}.$$  \hspace{1cm} \text{(2.22)}

In concluding this section, we emphasize once more that our purpose in introducing the unusual "external" field $\hat{Y}$ was to provide a pathway leading to the formulation, Eqs. (2.19)-(2.22), which form the basis for the further development. These relations also apply to systems with $\hat{Y} = 0$, which are the only systems that interest us henceforth.

### III. GENERALIZED KOHN-SHAM SCHEME

$n(x)_{I'I}$ is the limit $x \to x'$ of the off-diagonal one-body density matrix

$$\rho(xI|x'I') = \langle I'|\hat{\psi}^\dagger(x')\hat{\psi}(x)|I \rangle.$$  \hspace{1cm} \text{(3.1)}

Since $\rho$ is Hermitian and (as we shall show below) positive semi-definite in the direct product space labeled by $(x, I)$, it can be brought to diagonal form, a move that generalizes the concept of natural orbitals. We may thus write

$$\rho(xI|x'I') = \sum_J \lambda_J \Phi_J(xI)\Phi_J^*(x'I'),$$  \hspace{1cm} \text{(3.2)}

$$\lambda_J \geq 0,$$  \hspace{1cm} \text{(3.3)}

$$\sum_{I=1}^{M} \int dx \Phi_J^*(xI)\Phi_J(xI) = \delta_{JJ'},$$  \hspace{1cm} \text{(3.4)}

$$\int dx \rho(xI|x'I) = N\delta_{II'}.$$  \hspace{1cm} \text{(3.5)}

Here Eqs. (3.2) and (3.3) define the eigenfunctions and eigenvalues of the generalized density matrix, (3.4) expresses the property that the $\Phi_J(xI)$ are unit eigenvectors in the space labeled jointly by the single-particle coordinates and the eigenvalues of the states in the set $\mathcal{S}$, and (3.5) expresses number conservation. It follows from these equations that

$$\sum_{I=1}^{M} \int dx \rho(xI|xI) = \sum_J \lambda_J = NM.$$  \hspace{1cm} \text{(3.6)}

Before continuing the development, we interject the proof that $\rho(xI|x'I')$ is positive semi-definite. Toward this end we compare Eq. (3.2) with the form that follows directly from its definition

$$\rho(xI|x'I') = \sum_K \langle I'|\hat{\psi}^\dagger(x')|K \rangle \langle K|\hat{\psi}(x)|I \rangle,$$  \hspace{1cm} \text{(3.7)}

where $K$ is a complete set of intermediate states. Invoking the orthonormality relations (3.4), we thus conclude that for eigenvalues $\lambda_J \neq 0$, 

---

6
\[ \lambda_J = \sum_K \sum_{l=1}^{M} \int dx \Phi_J^*(x, I) \langle K | \hat{\psi}(x) | I \rangle^2 > 0. \] (3.8)

In imitation of ground-state KS theory, we introduce a mapping from the off-diagonal density to a quasi-independent-particle off-diagonal density,

\[ n(x)_{II'} \rightarrow n^s(x)_{II'}, \] (3.9)
\[ n^s(x)_{II'} = \sum_J \varphi_J(x) \varphi_J^*(xI), \] (3.10)
\[ \sum_{l=1}^{M} \int dx \varphi_J^*(xI) \varphi_J(xI) = \delta_{JJ'}, \] (3.11)
\[ \int dx n^s(x)_{II'} = N \delta_{II'}. \] (3.12)

Though we use the same symbol \( J \) to label orbitals as for the case of natural orbitals, here the similarity stops. For the latter, \( J \) is, in principle, an unbounded set. For the present alternative, the set labeled by \( J \) is strictly a finite set as determined by the sum (cf. (3.6)),

\[ \sum_J 1 = NM. \] (3.13)

Though the labels \( I \) have the same meaning in both the original space and in the mapped space, the fact that the labels \( J \) do not, leaves a vagueness at present about the significance of this quantum number. We shall see, however, that once we turn to applications in Sec. IV, there will be no problem in providing a precise characterization of this quantum label.

We next show how the variational principle may be used to obtain equations for the orbitals \( \varphi_J \) so that in fact the matrices \( n \) and \( n^s \) are equal. We utilize the variational principle in the form

\[ \sum_{JJ'} \int dx \frac{\delta H}{\delta \varphi_J^*(xI)} \delta \varphi_J(xI) + \text{c.c.} = 0. \] (3.14)

Imitating the procedure for the ground-state theory, we decompose the trace of the Hamiltonian,

\[ H = T^s + (V + W + T - T^s), \] (3.15)
\[ T^s = \sum_J \int \varphi_J^t(xI) \varphi_J(xI). \] (3.16)

Enforcing the equality of \( n \) and \( n^s \), we define an effective single-particle potential matrix,

\[ v^s(x)_{II'} = \frac{\delta}{\delta n(x)_{II'}} (V + W + T - T^s), \] (3.17)
\[ = \frac{\delta}{\delta n^s(x)_{II'}} (V + W + T - T^s). \] (3.18)

The discussion of the decomposition of this matrix single-particle operator into constituent parts of interest will be taken up in Sec. IV.
With the help of Eqs. (3.13-3.18), we derive from the variational principle (3.14) the conditions
\[ \sum_{II'} \int d\mathbf{x} \delta \varphi_j^*(\mathbf{x}I)[\tau \delta_{II'} + v^s(\mathbf{x})_{II'}] \varphi_j(\mathbf{x}I') + \text{c.c.} = 0. \] (3.19)

To derive generalized single-particle equations of motion from the variational principle, we add the constraint conditions
\[ -\sum_{II'} \int d\mathbf{x} \delta \varphi_j^*(\mathbf{x}I)[\epsilon_j \delta_{II'} + \nu(\mathbf{x})_{II'}] \varphi_j(\mathbf{x}I') + \text{c.c.} = 0. \] (3.20)

Here \( \epsilon_j \) is the Lagrange multiplier for the normalization condition contained as part of (3.11). (As usual, the orthogonality condition need not be imposed, since it will be automatically satisfied by the solutions of the emerging equations.) The unfamiliar term containing the Lagrange multiplier matrix \( \nu(\mathbf{x})_{II'} \) has the form of an additional potential matrix, whose purpose is to enforce the condition \[ n = n^s. \] We shall study this quantity further below. Combining Eqs. (3.19) and (3.20), we derive (together with its complex conjugate) the generalized single-particle equation
\[ \epsilon_j \varphi_j(\mathbf{x}I) = \sum_{II'} [\tau \delta_{II'} + v^s(\mathbf{x})_{II'} - \nu(\mathbf{x})_{II'}] \varphi_j(\mathbf{x}I'). \] (3.21)

At this juncture it is appropriate to wonder how (3.21) is related to the density and density-matrix forms of CKS theory. We cannot expect a general connection, since the latter describes the consequences of the application of a time-dependent external field, whereas in the theory under development, the “time dependence” is a purely internal matter expressed by an off-diagonal array of densities and effective potentials. Nevertheless, a connection between the two formalisms will be made for the application studied in Sec. IV, the so-called weak-coupling limit. In effect, it will be shown that this limit contains the same physics as the combination of TDDFT and linear response theory, and thus solves, in part, the task of establishing the “usefulness” of our approach.

We conclude the present section by showing that (cf. Eq. (2.22))
\[ \nu(\mathbf{x})_{II'} = \mu_{II'}, \] (3.22)
up to a global additive constant. It is thus a non-trivial matrix and cannot be absorbed into the eigenvalues \( \epsilon_j \). To prove (3.22), we can work backwards from the sum of (3.13) and (3.20) to the equation
\[ 0 = \sum_{II'} \int d\mathbf{x} \left[ \frac{\delta H}{\delta n^s(\mathbf{x})_{II'}} - \nu(\mathbf{x})_{II'} \right] \delta n^s(\mathbf{x})_{II'} \] (3.23)
\[ = \sum_{II'} \int d\mathbf{x} \left[ \frac{\delta H}{\delta n(\mathbf{x})_{II'}} - \nu(\mathbf{x})_{II'} \right] \delta n(\mathbf{x})_{II'} \] (3.24)
\[ = \sum_{II'} \int d\mathbf{x} \left[ \frac{\delta H}{\delta n(\mathbf{x})_{II'}} - \mu_{II'} \right] \delta n(\mathbf{x})_{II'}. \] (3.25)

In passing from (3.23) to (3.24), we have used the equality \( n^s = n \). In writing (3.25), we have repeated (2.21). Comparing (3.24) with (3.25), we arrive at (3.22), again up to an additive constant.
IV. APPLICATION TO THE WEAK COUPLING LIMIT

In the course of this section, we shall transform and approximate Eq. (3.21), leading to an eigenvalue equation that will determine off-diagonal elements of the matrix $n$. We shall do so in an approximation, the weak-coupling approximation, that is equivalent to a linear response approach. Assuming that the matrix $\mu$ can be chosen diagonal (see immediately below), the eigenvalues are the quantities

$$\omega_I = \mu_{II} - \mu_{00}. \quad (4.1)$$

The proof that the matrix $\mu$ can be chosen diagonal goes as follows: Though we trace over a set of states labeled $I$ and originally identified as eigenstates of the reference system, the entire formalism is invariant under a unitary transformation within the included space. Such a transformation can be chosen to diagonalize $\mu$ if it is not already diagonal. The relation of the quantities in Eq. (4.1) to the excitation energies of the system is not immediately apparent. The main result of this section suggests that they are equal. The proof that they are is given in Sec. V.

Though the derivation of the main result of this section, the eigenvalue equation, can be carried out directly from the generalized KS equation, we present the discussion in a form that makes more immediate contact with the density functional form of the theory. The first step, which is completely general, is to transform Eq. (3.21) into an equation for the matrix $n_{II'}^{s}(x, x')$. First rewrite Eq. (3.21), remembering Eq. (4.1), as

$$\epsilon_I\varphi_I(x) = \sum_{I'}(h_{II'}^{s}(x) - \omega_I \delta_{II'})\varphi_{I'}(x), \quad (4.2)$$

Recalling the definition

$$n_{II'}^{s}(xx') = \sum_{J} \varphi_{J}(x)\varphi_{J}^{*}(x'), \quad (4.3)$$

we can form from Eq. (4.2) and its complex conjugate two equivalent but distinct values of the sum $\sum_{J} \epsilon_J \varphi_J(x)\varphi_J^{*}(x'I')$. The difference of these forms yields the generalized density-matrix equation (using summation convention)

$$n_{II'}^{s}(xx')(\omega' - \omega_I) = \sum_{J} [n_{II'}^{s}(xx')h_{II'}^{s}(x') - h_{II'}^{s}(x)n_{II'}^{s}(xx')], \quad (4.4)$$

that will provide the starting point for our further considerations.

We note that by introducing time-dependent matrix elements

$$O_{II'}(t) = O_{II'} \exp[-i(\omega_I - \omega_{I'})t], \quad (4.5)$$

where $O$ takes on the values $n^{s}$ and $h^{s}$, Eq. (4.4), may be written in the form

$$-i\frac{d}{dt}n^{s}(t) = [n^{s}(t), h^{s}(t)]. \quad (4.6)$$

This resembles the fundamental equation of TDDFT, in density matrix form, except that the bold-face type reminds us that we are dealing with quantum-mechanical operators rather
than c-numbers. This can be converted into a form of TDDFT, however, by assuming the existence of a wave packet $|\Psi\rangle$ that is a linear combination of the ground state and excited states of interest, for which we can also replace the average of the products that appear in the commutator by the product of the averages.

In the following we concentrate on the study of the weak coupling approximation to Eq. (4.4). In this approximation one imagines that the set of states (2.7) can be divided into the ground-state $I = 0$ and states characterized as dominant $\nu$ quasiparticle- $\nu$ quasihole excitations (denoted by $I_\nu$) with respect to the ground-state. On the basis of this picture one may introduce a set of assumptions concerning relative orders of magnitude of certain matrix elements, whose validity is obvious in the limit of vanishing two-particle interaction,

$$|n_{00}^s| >> |n_{0I_1}^s| >> |n_{0I_2}^s| >> \ldots, \quad (4.7)$$

$$|n_{I_1I_1}^s| \approx |n_{00}^s|, \quad (4.8)$$

$$|n_{I_1I_1'}^s| \approx |n_{0I_2}^s| \text{ if } I_1 \neq I_1'. \quad (4.9)$$

We shall consider diagonal elements to be of zero order, elements connecting states $I_\nu$ to $I_{\nu+p}$ to be of $p$th order.

Considering assumption (4.8) first, it asserts that for $I$ belonging to the first few levels of the hierarchy, if $N$, the number of particles is not too small, in lowest approximation matrix elements diagonal in $I$ are equal to their value for $I = 0$. It is easiest to see this for the density itself, since the wave functions of the excited states differ from those of the ground state by at most a few particles out of $N$. That this property of matrix elements diagonal in $I$ follows for quantities other than the density itself is a consequence of their relation to the density, as will be seen from further study below. We shall consider all diagonal matrix elements to be zero order quantities. A further assumption, in terms of this scale, is that matrix elements in which $I$ and $I'$ belong to adjacent levels in the hierarchy are, on the average, of order $(1/\sqrt{N})$ compared to zero order quantities. For the sorting of our equations, we also need the assumption that matrix elements in which $I, I'$ differ by two levels or refer to two different states of the same level are second order quantities, i.e., of the order of the product of first order quantities. Of course, it has to be verified a posteriori that the solutions found are in accord with these statements.

Our aim is to apply these assumptions to choose those matrix elements of Eq. (4.4) that characterize the state 0 and the states $I_1$. To carry out this program, we must look more closely into the structure of the effective interaction $v^s$. First we rewrite the trace of the Hamiltonian in the form

$$H = T^s + V + W^c + H^{xc}, \quad (4.10)$$

$$W^c = \frac{1}{2} \int dx dx' \sum_{II'} n^s_{II'}(x) \frac{1}{|x-x'|} n^s_{I'I}(x'), \quad (4.11)$$

which defines $H^{xc}$. It follows that

$$v^s_{II'}(x) = \frac{\delta}{\delta n^s_{I'I}(x)}(V + W^c + H^{xc}) \quad (4.12)$$

$$= v(x)\delta_{II'} + v^c_{II'}(x) + v^{xc}_{II'}, \quad (4.13)$$

$$v^c_{II'}(x) = \int dx' \frac{1}{|x-x'|} n^s_{II'}(x'). \quad (4.14)$$
The main reason for exhibiting these formulae is to recognize, as we shall see in more detail below, that the off-diagonal elements of \( h \) are at least linear in the corresponding off-diagonal elements of \( n^s \). This is obvious from Eq. (4.14) for the Coulomb contribution and will be argued more closely later for \( v^{xc} \). Thus we may safely assume that that the matrix elements of \( h \) are the same order of magnitude as the corresponding matrix elements of \( n^s \).

Turning then to our major task, which is to study the matrix elements of Eq. (4.4), we consider first the ground or 00 element. Neglecting terms of second order and higher, we find

\[
[n_{00}^s(xx')h_{00}(x') - h_{00}(x)n_{00}^s(xx')] = 0. \tag{4.15}
\]

It is consistent with our approximations to identify \( n_{00}^s \) (in leading approximation only) with the ground state density of KS theory and \( h_{00}^s(x) \) with the KS single-particle Hamiltonian. Equation (4.15) is thus the KS equation in density matrix form and determines a complete eigenvalue problem. First we have (the matrix elements in question are local functions of \( x \))

\[
\omega_1 n_{01}^s(xx') = [n_{00}^s(xx')h_{01}^s(x') + n_{01}^s(xx')h_{11}^s(x') - h_{00}^s(x)n_{01}^s(xx') - h_{01}^s(x)n_{11}^s(xx')]. \tag{4.16}
\]

As a first step in the evaluation of this equation, we may, according to Eq. (4.8), set the \( n_{11} \) matrix elements equal to the \( n_{00} \) ones. We also drop the subscripts 00 understanding these according to the previous identification to be the standard KS quantities. If we can exhibit \( h_{01}^s \) as an (approximate) linear functional of \( n_{01}^s \), Eq. (4.14) will have the form of a linear eigenvalue problem. First we have (the matrix elements in question are local functions of \( x \))

\[
h_{01}^s(x) = v_{01}^c(x) + v_{01}^{xc}(x), \tag{4.17}
\]

\[
v_{01}^c(x) = \int dxx' \frac{1}{|x - x'|} n_{01}^s(x'). \tag{4.18}
\]

We see that \( v^c \) is, by definition, already of the desired form.

We turn then to \( v^{xc} \). Our approach to this quantity is to revert to the study of \( H^{xc} \), defined in Eq. (4.10), which we consider, in line with assumptions previously made, a functional of \( n_{00} \approx n \), of \( n_{01}^s \), and of \( n_{10}^s \), the latter two considered as small quantities. (It is also a functional of the other off-diagonal elements, \( n_{01}^s \) and \( n_{10}^s \), where \( 1' \) refers to any of the other states at level one of the hierarchy of states. It is simply that this dependence does not enter into the current discussion.) We then expand \( H^{xc} \) as a functional Taylor series in these quantities,

\[
H^{xc} = H^{xc}|_0 + \int dxx' \frac{\delta H^{xc}}{\delta n_{10}^s(x)} |_{0} n_{10}^s(x) + \int dxx' \frac{\delta H^{xc}}{\delta n_{01}^s(x)} |_{0} n_{01}^s(x)
\]

\[
+ \int dxx' \frac{1}{2} \frac{\delta^2 H^{xc}}{\delta n_{10}^s(x) \delta n_{01}^s(x')} |_{0} n_{10}^s(x) n_{10}^s(x') + \int dxx' \frac{\delta^2 H^{xc}}{\delta n_{10}^s(x) \delta n_{01}^s(x')} |_{0} n_{10}^s(x) n_{01}^s(x')
\]

\[
+ \int dxx' \frac{1}{2} \frac{\delta^2 H^{xc}}{\delta n_{01}^s(x) \delta n_{01}^s(x')} |_{0} n_{01}^s(x) n_{01}^s(x') + \ldots . \tag{4.19}
\]
Strictly, the quantity $H^{xc}_0$ and its functional derivatives still depend on $n_{11}$ as well as $n_{00}$. It suffices to ignore the difference of the two quantities in the present discussion, but we shall have to remember and include the difference in the arguments of Sec. V. We note further that only the first and fourth of the terms shown explicitly in this equation are non-vanishing. Recall that $H^{xc}$ is a trace and therefore invariant under a unitary transformation in the space of states $I$. Its dependence on the matrix $n$ must also be in the form of traces over these indices. As we can see on the example of the Coulomb interaction, this dependence is more general than traces of products of $n$ at the same point, but in any event it follows that for every factor of $n_{10}^s$ at some spatial point, there must be a factor of $n_{01}^s$, at a generally different point. The simplification described above follows. We thus compute to first order

$$v_{01}^{\xi}(x) = \int dx' \frac{\delta^2 H^{xc}}{\delta n_{10}^s(x) \delta n_{01}^s(x')} |_0 n_{01}^s(x')$$

$$\equiv \int dx' f_{10,10}(|x-x'|, n)n_{01}^s(x')$$

$$\approx \int dx' f(|x-x'|, n)n_{01}^s(x'). \quad (4.20)$$

In passing from the second to the third line of this equation, i.e., in ignoring the state-dependence of $f$, we are making an approximation equivalent to the adiabatic approximation widely used in TDDFT. With the definition (the dependence on $n$ being understood)

$$f^{eff}(|x-x'|) = \frac{1}{|x-x'|} + f(|x-x'|), \quad (4.21)$$

Eq. (4.16) may be rewritten as (using $h^s(xx'') = \delta(x-x')h^s(x)$ for convenience)

$$\omega_1 n_{01}^s(xx') = \int dx'' n^s(xx') f^{eff}(|x''-x''|)n_{01}^s(x'') + n_{01}^s(xx'')h^s(xx'')$$

$$- h^s(xx'')n_{01}^s(x''x') - n^s(xx')f^{eff}(|x-x''|)n_{01}^s(x''). \quad (4.22)$$

The final task with respect to this equation is to convert it into a standard RPA form. Toward this end we reexpress the matrices $n^s$ and $n_{01}^s$ in terms of the KS single-particle functions, $\varphi_a(x)$, satisfying the KS equation

$$\int dx' h^s(xx')\varphi_a(x') = \epsilon_a \varphi_a(x). \quad (4.23)$$

First of all we have the familiar equation

$$n^s(xx') = \sum_h \varphi_h(x)\varphi_h(x'). \quad (4.24)$$

Next we must evaluate the sum

$$n_{01}^s(xx') = \sum_J \varphi_J(x0)\varphi_J^*(x1). \quad (4.25)$$

Here we must introduce assumptions concerning which values of $J$ contribute to the required order. In the space of the eigenstates of the fully interacting system, we are concerned with
the ground state and with states that are quasiparticle-hole (qph) excitations of this state. When we remove one particle from (create a hole \( h \) in) such a state, we expect to encounter states that can be characterized as either \( 0^h \) or \( 1^h \), and these are the values of \( J \) that we assign in the sum (4.25). If we consistently use the approximations \( \varphi_{0h}(0) \approx \varphi_{1h}(1) \approx \varphi_h \), the weak-coupling value of Eq. (4.25) becomes

\[
\frac{n^s_{01}(xx')}{h} = \sum_{h} [\varphi_h(x)\varphi_{0h}^*(x') + \varphi_{1h}(x)\varphi_{h}^*(x')]. \tag{4.26}
\]

The final form for this quantity is achieved by expanding the first-order amplitudes in terms of KS modes,

\[
\varphi_{0h}(1) = \sum_p \varphi_p X_{ph}, \tag{4.27}
\]

\[
\varphi_{1h}(0) = \sum_p \varphi_p Y_{ph}^*. \tag{4.28}
\]

The restriction of the sums on the right-hand sides of these equations is also consistent with the weak-coupling picture painted above. Strictly the amplitudes \( X, Y \) should carry superscripts 1, identifying the eigenstate to which they refer, but we shall suppress these except when required for clarity, as in Sec. V. Finally then,

\[
\frac{n^s_{01}(xx')}{h} = \sum_{p,h} [\varphi_h(x)\varphi_p^*(x')X_{ph}^* + \varphi_p^*(x)\varphi_h(x')Y_{ph}^*]. \tag{4.29}
\]

Introducing Eqs. (4.24) and (4.29) into Eq. (4.22), we can project out equations for \( X_{ph}^* \) and \( Y_{ph}^* \). We quote the complex conjugate of these equations:

\[
(\epsilon_h - \epsilon_p + \omega_1)X_{ph} = (f_{eff})_{hp/1ph'}X_{ph'} + (f_{eff})_{pp'h'h'}Y_{ph'}, \tag{4.30}
\]

\[
(\epsilon_h - \epsilon_p - \omega_1)Y_{ph} = (f_{eff})_{hp/1ph'}Y_{ph'} + (f_{eff})_{pp'h'h'}X_{ph'}, \tag{4.31}
\]

\[
(f_{eff})_{abcd} = \int dx dx' \varphi_a^*(x)\varphi_b^*(x')f_{eff}(|x - x'|)\varphi_c(x)\varphi_d(x'). \tag{4.32}
\]

The equations found are of the same form as those of the random phase approximation (RPA) and agree in detail with the eigenvalue equation that has been derived from the density-matrix version of CKS theory. Solutions are to be normalized in the usual way, according to the conditions (Appendix B),

\[
\sum_{ph}(|X_{ph}|^2 - |Y_{ph}|^2) = 1. \tag{4.33}
\]

As is well known, two different non-degenerate solutions of the RPA equations are orthogonal with the same metric as in (4.33).

It is important to emphasize what has been accomplished by the calculations of this section. With the help of Eq. (4.29), for instance, we can calculate the off-diagonal matrix elements of the density operator between the ground state and the first level of excited states. This can be applied, for example to the calculation of the corresponding matrix elements of the electric dipole moment. We have yet to establish, however, that the eigenvalues \( \omega_1 \) can be identified as the excitation energies of the system. We turn to this task now.
V. EXCITATIONS AS ENERGY DIFFERENCES

In principle the energy differences can be calculated from the expression

\[
\Delta E = \sum_{I=0,1} \langle I | \hat{H} | I \rangle - 2 \langle 0 | \hat{H} | 0 \rangle = E_1 - E_0,
\]

(5.1)

where \( E_I \) is the energy of state \( I \). This difference will be evaluated with the aid of Eqs. (4.10), (4.17), and the simplified version of (4.19). The result that we shall establish is

\[
E_1 - E_0 = \sum_{p,h} \{ (\epsilon_p - \epsilon_h) \left[ |X_{ph}|^2 - |Y_{ph}|^2 \right] + X_{ph}^* \left[ f_{ph'hh'} X_{p'h'} + f_{pp'hh'} Y_{p'h'} \right]
\]

\[
+ Y_{ph}^* \left[ f_{hp'hh'} X_{p'h'} + f_{hh'pp'} X_{p'h'} \right].
\]

(5.2)

But the right hand side of this equation is easily seen from Eqs. (4.30) and (4.31) to equal \( \omega_1 \), provided that we make use of Eq. (4.32).

It is simplest to evaluate the difference (5.1) first for the interaction terms. Consider, for instance, the Coulomb difference,

\[
\begin{align*}
\Delta W^c &= \int d\mathbf{x} d\mathbf{x}' \frac{1}{2 |\mathbf{x} - \mathbf{x}'|} \left[ n_{11}^s(\mathbf{x}) n_{11}^s(\mathbf{x}') - n_{00}^s(\mathbf{x}) n_{00}^s(\mathbf{x}') + 2 n_{01}^s(\mathbf{x}) n_{10}^s(\mathbf{x}') \right] \\
&\approx \int d\mathbf{x} d\mathbf{x}' \frac{1}{|\mathbf{x} - \mathbf{x}'|} \left[ \left[ n_{11}^s(\mathbf{x}) - n_{00}^s(\mathbf{x}) \right] n_{00}^s(\mathbf{x}') + n_{01}^s(\mathbf{x}) n_{10}^s(\mathbf{x}') \right], \\
&= \int d\mathbf{x} \left[ n_{11}^s(\mathbf{x}) - n_{00}^s(\mathbf{x}) \right] v^c(\mathbf{x}) + \int d\mathbf{x} d\mathbf{x}' \frac{1}{|\mathbf{x} - \mathbf{x}'|} n_{01}^s(\mathbf{x}) n_{10}^s(\mathbf{x}').
\end{align*}
\]

(5.3)

To obtain the value exhibited in the first line, we have made the quasi-boson approximation \( n_{12}^s = \sqrt{2} n_{01}^s \), which is an expression of the closure approximation referred to in Sec. II and discussed in more detail below. The further simplification is made possible by the fact that the difference \( n_{11}^s - n_{00}^s \) (see below) is quadratic in the RPA amplitudes. The corresponding difference involving the exchange-correlation energy can be written

\[
\Delta W^{xc} = \int d\mathbf{x} \left[ n_{11}^s(\mathbf{x}) - n_{00}^s(\mathbf{x}) \right] v^{xc}(\mathbf{x}) + \int d\mathbf{x} d\mathbf{x}' \left[ n_{01}^s(\mathbf{x}) n_{10}^s(\mathbf{x}') \right],
\]

(5.4)

Next we see that the second terms of Eqs. (5.3) and (5.4) combine to give

\[
\begin{align*}
\int d\mathbf{x} d\mathbf{x}' f^{cI} \left[ |\mathbf{x} - \mathbf{x}'| \right] n_{01}^s(\mathbf{x}) n_{10}^s(\mathbf{x}') &= X_{ph}^* \left[ f_{ph'hh'} X_{p'h'} + f_{pp'hh'} Y_{p'h'} \right] \\
&+ Y_{ph}^* \left[ f_{hp'hh'} Y_{p'h'} + f_{hh'pp'} X_{p'h'} \right],
\end{align*}
\]

(5.5)

which has been evaluated with the help of Eq. (4.29). This is already seen to be the interaction terms of Eq. (5.2).

The remaining terms of Eqs. (5.3) and (5.4), as well as the contributions arising from the kinetic energy and the external potential depend on the value of

\[
n_{11}^s(\mathbf{x}) - n_{00}^s(\mathbf{x}) = \sum_j [\varphi_j^*(\mathbf{x}1) \varphi_j(\mathbf{x}1) - \varphi_j^*(\mathbf{x}0) \varphi_j(\mathbf{x}0)].
\]

(5.6)
To enumerate the states $J$ that contribute to this difference it is useful to picture the state as an elementary boson excitation, as is done in the standard approach to the RPA. The relations that follow from this assumption will lead, as we shall see, to a quantitative form of closure approximation that is essential to the calculation. By the notation $1 \times 1$, we shall mean a double boson excitation with the same boson, whereas by $1 \times 1'$ we shall mean a double excitation with different bosons. Thus for the amplitudes $\varphi_J(1)$, we consider the values $J = 0h, 1h, 1 \times 1h, 1 \times 1'h$. The contributions from the latter two choices are evaluated in boson (closure) approximation as

$$\varphi_{1\times1h}(1) = \sqrt{2} \varphi_1(0),$$

$$\varphi_{1\times1'h}(1) = \varphi_{1'}(0).$$

For the amplitude $\varphi_J(0)$, the required values are $J = 0h, 1h, 1'h$. For the difference (5.6), we thus find, suppressing coordinate indices,

$$n^s_{11} - n_{00}^s = \sum_h [\varphi_{0h}^*(1)\varphi_{0h}(1) + \varphi_{1h}(0)\varphi_{1h}(0) + \varphi_{1h}^*(1)\varphi_{1h}(1) - \varphi_{0h}^*(0)\varphi_{0h}(0)].$$

The total contribution of the first two terms of Eq. (5.9) to the energy difference under study, obtained by substituting Eqs. (5.7) and (5.8) and applying the result to the sum of single-particle operators that add up to the KS Hamiltonian $h^s$, is found to be $\sum_{p,h}[\varepsilon_p(|X_{ph}|^2 + |Y_{ph}|^2)]$, one of the single-particle terms in Eq. (5.2). The evaluation of the remaining terms of Eq. (5.9) is carried through by studying the normalization conditions, Eq. (3.11). We calculate

$$1 = \sum_I |\varphi_{0h}(I)|^2$$

$$= |\varphi_{0h}(0)|^2 + |\varphi_{0h}(1)|^2 + \sum_{I' \neq I} |\varphi_{0h}(I')|^2,$$

$$1 = \sum_I |\varphi_{1h}(I)|^2$$

$$= |\varphi_{1h}(1)|^2 + |\varphi_{1h}(0)|^2 + |\varphi_{1h}(1 \times 1')|^2 + \sum_{I' \neq 1} |\varphi_{1h}(I')|^2$$

$$\approx |\varphi_{1h}(1)|^2 + |\varphi_{1h}(0)|^2 + 2|\varphi_{0h}(1)|^2 + \sum_{I' \neq 1} |\varphi_{0h}(I')|^2,$$

where the last evaluation has made use of the boson approximation expressed by Eqs. (5.7) and (5.8). These equations are satisfied by introducing a renormalization of the KS orbitals

$$\varphi_{0h}(x0) = \varphi_h(x)[1 - \frac{1}{2} \sum_p |X_{ph}|^2 - \frac{1}{2} \sum_{I' \neq 1} |X_{ph}^{I'}|^2],$$

$$\varphi_{1h}(x1) = \varphi_h(x)[1 - \sum_p |X_{ph}|^2 - \frac{1}{2} \sum_p |Y_{ph}|^2 - \frac{1}{2} \sum_{I' \neq 1} |X_{ph}^{I'}|^2].$$

Combining these results and applying them to the last two terms of Eq. (5.9), suitably multiplied by the sum of terms that comprise $h^s$ leads to the final contribution $\sum_{p,h}[-\varepsilon_h(|X_{ph}|^2 + |Y_{ph}|^2)]$ to the theorem stated in Eq. (5.2).
VI. CONCLUDING REMARKS

In this paper, we have developed an alternative formalism for the study of excited states within a framework that generalizes the basic ideas of KS theory. The main novelty in our approach compared to other methods is that the latter work with a single density, be it the average in the ground state, in an excited state, an ensemble average, or the average in a suitably chosen time-dependent state. On the other hand, we arrive at a formalism involving an entire array of matrix elements of the density operator taken among a pre-selected set of states. The application of the variational principle for the trace of the Hamiltonian then leads to a generalized KS scheme in terms of orbitals that depend not only on the coordinate $x$, but also on a label $I$ of the included states. We have examined the consequences of this formalism for the weak-coupling limit. We did this by framing a set of assumptions, including a closure approximation, in order to identify the most important amplitudes and their equations that characterize the ground state and a simple class of excited states that are composed of $1p-1h$ excitations of the ground state.

In this way, we regained first the ground-state KS theory and second derived an eigenvalue equation of RPA form. By approximating a state-dependent (frequency-dependent) effective interaction by a state-independent (frequency independent) effective interaction, the eigenvalue equation became identical to one that was first derived from the density-matrix version of CKS theory [12].

In our formalism, it is not immediately obvious that the eigenvalues, which originally entered the theory as Lagrange multipliers in a variational principle, can be identified with excitation energies of the physical system. We prove that this is correct identification, in agreement with previous results. The theory also provides the means for the computation of electromagnetic transition rates from the excited states to the ground state. As formulated, the theory described in this paper can be extended to improve the approximations made for $1qp - 1qh$ states, as well as to study more complicated states, for example, of $2qp - 2qh$ character.

APPENDIX A: RELATION OF WEAK-COUPLING LIMIT TO TIME-DEPENDENT DENSITY FUNCTIONAL THEORY

In this section, we shall connect the linearized RPA equations (4.30) and (4.31) with a corresponding linearized approximation to TDDFT. We start with TDDFT in density-matrix form

\[ i \frac{d\rho^s}{dt} = [(\tau + v^s(t)), \rho^s], \]

(A1)

\[ \rho^s(xt, x't) = \sum_h \varphi_h(xt) \varphi^*_h(x't), \]

(A2)
\[
v^s(xt) = \frac{\delta}{\delta n(xt)}(V(t) + W(t) + T(t) - T^s(t)). \tag{A3}
\]

Here \( \varphi(xt) \) are the \( N \) instantaneous eigenfunctions of \( \tau + v^s(t) \) of lowest energy, defining a time-dependent Slater determinant whose kinetic energy is \( T^s(t) \), and \( V(t) \), for example, is the expectation value of \( \hat{V} \) in the time-dependent wave-function \( |\Psi(t)\rangle \).

We are interested in the physical situation where the time-dependence of the state vector arises not from an explicitly time-dependent external field but from the fact that initially the state vector is a superposition of the ground state (predominately) and a small amplitude for one of the excited states. We thus assume that

\[
\rho^s(xt, xt') = \rho^0(x, x') + [\rho^1(x, x') \exp(-i\omega t) + \text{c.c.}], \tag{A4}
\]

\[
\rho^1(x, x') = \sum_{ph} [X_{ph}\varphi_p(x)\varphi^*_h(x') + Y_{ph}\varphi_h(x)\varphi^*_p(x')]. \tag{A5}
\]

In (A4) and below the superscript 0 identifies quantities associated with the KS ground-state theory.

What follows now is close to a standard derivation of the RPA. We insert (A4) and (A5) into (A1) and, considering the amplitudes \( X \) and \( Y \) as first order quantities, we expand to first order. For this purpose, we need the expansion,

\[
v^s(xt) = v^0(x) + \int dx' f(x, x') n^1(x'), \tag{A6}
\]

\[
f(x, x') = \frac{\delta v^0(x)}{\delta n^0(x')}, \tag{A7}
\]

\[
n^1(x) = \rho^1(x, x). \tag{A8}
\]

In Eqs. (A6) and (A7), we have already made the adiabatic approximation by ignoring the time dependence of \( f \). As a consequence, the quantity called \( f \) in this appendix can be identified with the quantity \( f^{eff} \) of the text. From the zero order term, we regain the KS theory for the ground state. From the first order terms proportional to \( \exp(-i\omega t) \), for example, we find

\[
\omega \rho^1(x, x') = [(\tau + v^0), \rho^1](x, x') + \int dx'' \left[ \frac{\delta v^0}{\delta n(x'')}, \rho^0 \right](x, x') n^1(x''). \tag{A9}
\]

Taking, in turn, the \( qph \) and \( qhp \) matrix elements of (A9), we find the familiar equations

\[
[\epsilon_h - \epsilon_p + \omega] X_{ph} = f_{ph'hp'} X_{p'h'}, \tag{A10}
\]

\[
[\epsilon_h - \epsilon_p - \omega] Y_{ph} = f_{hp'h'p} Y_{p'h'}, \tag{A11}
\]

APPENDIX B: RPA NORMALIZATION CONDITION

We define mode operators, \( a_a \), for the field \( \hat{\psi}(x) \) by expanding in terms of the KS modes,

\[
\hat{\psi}(x) = \sum_a a_a \varphi_a(x), \tag{B1}
\]
\[a = \{h, p\}\]. From the commutation relations for quasiparticle-quasihole pairs,

\[ [a_h^\dagger a_p, a_{p'}^\dagger a_{h'}] = \delta_{hh'}\delta_{pp'} - \delta_{hh'}a_{p'}^\dagger a_p - \delta_{pp'}a_{h'}^\dagger a_h, \]  

we obtain an approximate sum rule by taking the expectation value in the state \(|0\rangle\), introducing a complete set of intermediate states \(|i\rangle\), and retaining only the first term on the right hand side (on the justified assumption that, for instance, \(\langle 0|a_{p'}^\dagger a_p|0\rangle\) is, on the average small compared to unity). With the definitions

\[\xi_{ph}^i = \langle 0|a_h^\dagger a_p|i\rangle, \]  
\[\eta_{ph}^i = \langle 0|a_p^\dagger a_h|i\rangle, \]  

we have

\[\sum_i [\xi_{ph}^i\xi_{p'h'}^* - \eta_{p'h'}^i\eta_{ph}^*] = \delta_{pp'}\delta_{hh'}. \]  

We would like to identify the quantities \(\xi\) and \(\eta\) with the quantities \(X\) and \(Y\), where the latter satisfy Eqs. \((4.30)\) and \((4.31)\). Equation \((B5)\) would then constitute the completeness relation for the solutions of these equations, and as is well-known, a completeness relation and orthogonality of solutions with the corresponding metric implies the normalization condition Eq. \((4.33)\). Toward this end, we consider two different evaluations of \(\langle 0|\hat{\psi}(x)\hat{\psi}(x)|i\rangle = n_{i0}(x)\). On the one hand we have in an approximate evaluation based on the physical picture,

\[n_{i0}(x) = \sum_{ab} \varphi_a^*(x)\varphi_b(x)\langle 0|a_a^\dagger a_b|i\rangle \]
\[\approx \sum_{ph} [\varphi_p^*(x)\varphi_h(x)\langle 0|a_p^\dagger a_h|i\rangle + \varphi_p^*(x)\varphi_h(x)\langle 0|a_h^\dagger a_p|i\rangle]. \]  

On the other hand, from the generalized KS mapping \(n_{i0} \to n_{i0}^*\) and Eq. \((4.29)\), we have

\[n_{i0}(x) = \sum_{ph} [\varphi_p^*(x)\varphi_h(x)Y_{ph}^i + \varphi_h^*(x)\varphi_p(x)X_{ph}^i]. \]  

The identifications \(\xi = X\) and \(\eta = Y\) are consistent with these equations.
