November 26, 2020

Abstract

We analyze a quasi-static Biot system of poroelasticity for both compressible and incompressible constituents. The main feature of this model is a nonlinear coupling of pressure and dilation through the system’s permeability tensor. Such a model has been analyzed previously from the point of view of constructing weak solutions through a fully discretized approach. In this treatment, we consider simplified Dirichlet type boundary conditions in the elastic displacement and pressure variables and give a full treatment of weak solutions. Our construction of weak solutions for the nonlinear problem is natural and based on a priori estimates, a requisite feature in addressing the nonlinearity. This is in contrast to previous work which exploits linearity or monotonicity in the permeability, both of which are not available here. We utilize a spatial semi-discretization and employ a multi-valued fixed point argument in for a clear construction of weak solutions. We also provide regularity criteria for uniqueness of solutions.

Keywords: poroelasticity, nonlinear coupling, implicit evolution equations, fixed point methods

1 Introduction

Poro-elasticity refers to fluid flow (Darcy flow) within a deformable, porous medium. The development of this field has been inspired by geophysics and petroleum engineering problems, in particular reservoir, environmental and earthquake engineering. Mathematically, the subject was initiated by the 1D work of Terzaghi in the 1920s, and the groundbreaking consolidation theory developed by Biot in the 1940–50s \cite{3}, which started the rapid development and progress of this field. The related literature is now abundant, and we only list here representative fundamental treatments: \cite{2,6,10,11,17,20,25}. In all of the works motivated by geophysical applications, the poroelastic structures under consideration are typically soil and/or rock (for instance, in most of the aforementioned references). However, cartilages, bones, as well as brain, heart, and liver tissue etc., are also examples of poroelastic structures. Therefore, the theory of poroelasticity can be used and applied to fluid flows inside cartilages, bones, and engineered tissue scaffolds, as well as in perfusion in the optic nerve head—see \cite{3,5,21} and references and discussion therein.

From a mathematical point of view, poroelastic systems constitute coupled systems of a (possibly degenerate) parabolic fluid pressure and a hyperbolic (inertial) or elliptic (non-inertial) system
of elasticity for the displacement of the porous matrix containing the fluid. The saturated elastic matrix is modeled through homogenization, in the sense that the pressure and displacement are distributed quantities throughout the physical domain. In this treatment, we focus on poroelastic models with specific applications in biomechanics (in contrast to those tailored to geomechanical systems). Thus we work under the assumptions of full saturation, negligible inertia, small deformations, and (possibly) compressible mixture components. The applications of interest give rise to a Biot permeability taken as a nonlinear function of the fluid content (a particular linear combination of pressure and dilation). This type of nonlinear coupling introduces a variety of complications detailed below, and in particular destroys the monotone nature of the problem.

Such a nonlinear poroelastic model was first considered—from a mathematical point—in [6], and shortly after in [3, 4]. The former reference [6] (and latter [7]) focus on the compressible Biot model and constructs weak solutions through a full spatio-temporal discretization, in the mathematically simplified framework of homogeneous Dirichlet boundary conditions for both fluid pressure and solid displacement. This reference takes the linear theory developed by Showalter [19, 20] as its primary motivation, and uses Brouwer’s fixed point at the level of the fully discretized problem. The latter reference [4] focuses on Biot models with incompressible constituents and constructs weak solutions (also using discretizations in both time and space [25]) for both poroelastic and poro-viscoelastic systems with non-homogeneous mixed boundary conditions that are physically relevant to ophthalmological applications. A key theme in that work is the careful analysis of the requisite boundary and source regularity for the construction of weak solutions, as this aspect is crucial in understanding the mechanisms leading to tissue damage in the optic nerve head, and consequent vision loss, associated with glaucoma. Both [4, 6] obtain a priori estimates in the fully discretized setting and much of the challenge lies in adequately addressing the nonlinear and non-monotone coupling to obtain a weak solution in the limit. The reference [6] provides a straightforward regularity criterion for uniqueness of solutions, but does not actually consider smooth solutions, nor address the permissibility of requisite multipliers used to obtain estimates.

In this treatment, we aim to provide a careful and precise mathematical construction of weak solutions using only semi-discretization in space, in the setting of fully homogeneous boundary conditions. One primary goal is to clearly elucidate the challenges introduced into the Biot problem by the inclusion of non-monotone nonlinear coupling. We also include a new, sharper uniqueness criterion for solutions of sufficient smoothness. Our approach is based on rigorously obtained a priori estimates for the time-dependent linearization, from which we construct a fixed point correspondence. An interesting feature of this approach is that we cannot appeal to uniqueness of solutions for the aforementioned linear problem. Indeed, weak solutions themselves are not permissible test functions, presenting a great hurdle in the analysis. To address this issue, we utilize a multi-valued fixed point approach, along with a careful construction of the correspondence between the permeability function and the resulting fluid content.

In summary, this paper addresses existence of weak solutions to a nonlinear Biot system based on a natural fixed point approach which circumvents the lack of monotonicity in the system’s nonlinear coupling. We utilize a semi-discretization approach (in space), since a relevant time-dependent, nonlinear implicit evolution framework does not seem to be readily available. We believe that the construction given here is the most natural and most illustrative of the complications in the analysis introduced by the presence of nonlinearity and its interaction with the boundary conditions.

1We note that in [21] a nonlinear version of the Biot problem is considered, but the structure of the nonlinearity there is monotone in nature and different from the physical nonlinearity presented here for biological applications.
1.1 PDE Model

Let $\Omega$ be an open, bounded subset of $\mathbb{R}^3$ representing the spatial domain occupied by the fluid-solid mixture, with smooth boundary $\Gamma = \partial \Omega$. Let $x$ be the position vector of each point in the body with respect to a fixed Cartesian reference frame. The symbol $n$ will be used to denote the unit outward normal vector to $\Omega$. Let $V_f(x, t)$ be the volume occupied by the fluid component in a representative volume $V(x, t)$ element centered at $x \in \Omega$ at time $t$. Then the porosity $\phi$ and the fluid content $\zeta$ are given by $\phi(x, t) = V_f(x, t)/V(x, t)$ and $\zeta(x, t) = \phi(x, t) - \phi_0(x)$, where $\phi_0$ is a baseline (local) value for the porosity.

Balance Equations: Under the assumptions of small deformations, full saturation of the mixture, and negligible inertia, we can write the balance of linear momentum for the mixture and the balance of mass for the fluid component as

$$\partial_t \zeta + \nabla \cdot \mathbf{v} = S(x, t) \quad \text{and} \quad -\nabla \cdot \mathbf{T} + \mathbf{F}(x, t) = 0 \quad \text{in} \quad \Omega \times (0, T) \quad (1.1)$$

where $\mathbf{T}$ is the total stress, $\mathbf{v}$ is the discharge velocity, $\mathbf{F}$ is a body force per unit of volume, and $S$ is a net volumetric fluid production rate.

Constitutive Equations: We complement the balance equations with the following constitutive equations.

The total stress of the mixture is given by

$$\mathbf{T} = \mathbf{T_e} - \alpha \mathbf{p} \mathbf{I} = 2\mu_e \varepsilon(u) + \lambda_e (\nabla \cdot u) \mathbf{I} - \alpha \mathbf{p} \mathbf{I}, \quad (1.2)$$

where $u$ is the solid displacement, the symmetrized gradient $\varepsilon(u) = (\nabla u + \nabla u^T)/2$ is the strain tensor, $\alpha$ is the Biot-Willis constant, $p$ is the Darcy fluid pressure, $I$ is the identity tensor, and $\lambda_e$ and $\mu_e$ are the Lamé elastic parameters.

The discharge velocity has the following formula via Darcy’s law [20]:

$$\mathbf{v} = -k(\phi) \nabla p. \quad (1.3)$$

The particular form of the relationship between the permeability $k$ and the porosity $\phi$ depends on the geometrical architecture of the pores inside the matrix and the physical properties of the fluid. We allow for $k$ to be a general continuous function, assuming only that it is bounded above and below (as discussed below, in Assumption 1.1, and consistent with [4, 6]).

The fluid content is given by

$$\zeta = c_0 p + \alpha \nabla \cdot u, \quad (1.4)$$

where $c_0$ is the constrained specific storage coefficient [11]. Using the relation between porosity and fluid content, as well as the definition of permeability, we can see that permeability in the system depends nonlinearly on the fluid content. In the special case of incompressible constituents, due to the fact that the constrained storage coefficient $c_0 = 0$ and $\alpha = 1$, the permeability becomes a nonlinear function of dilation alone. This is the scenario that is specifically addressed in [4].

Boundary Conditions: We consider homogeneous Dirichlet boundary conditions for both the structural displacement $u$ (and hence $u_t$, when defined) and the fluid pressure $p$.

$$u = 0, \quad p = 0 \quad \text{on} \quad \Gamma. \quad (1.5)$$
This choice is in line with the model considered in \cite{6,15}. In our previous work \cite{4}, we considered more complex physical configurations, incorporating both Dirichlet and Neumann boundary conditions for the elastic displacement and fluid pressure. These physical mixed boundary conditions could be incorporated here, and existence and uniqueness of weak solution would follow similarly.

**Initial Conditions:** \( \zeta(x,0) = d_0 \) in \( \Omega \).

**Remark 1.1.** In discussing stronger notions of solutions (as in Section 6), one can find the requirement that \( d_0 = \zeta(0) = [c_0 p + \alpha \nabla \cdot u](0) \) for some \( u(t = 0) = u_0 \) specified independently of \( d_0 \), taken in an appropriate space (see \cite{23}, as well as \cite{3}). In these works, a different construction for solutions is utilized. We do note that for the linear case, in the most general “weak” setting \cite{20}, only \( d_0 \) is needed. In this weak situation, the construction is done independent of a priori estimates obtained in standard Hilbert spaces such as \( L^2(\Omega) \) and \( H^1_0(\Omega) \). In \cite{15}, solutions are also constructed in the linear case, but the initial data is taken to be smoother than “finite energy” considerations would require.

**PDE System:** To summarize, below is the PDE nonlinear coupling that we are considering:

\[
\begin{align*}
  - \nabla \cdot [2 \mu e(u)p + \lambda_e (\nabla \cdot u)] - \alpha p I &= F \quad \text{in } \Omega \times (0,T) \quad (1.6) \\
  \zeta_t - \nabla \cdot [k(\zeta) \nabla p] &= S \quad \text{in } \Omega \times (0,T) \quad (1.7) \\
  \zeta = c_0 p + \alpha \nabla \cdot u \quad \text{in } \Omega \times (0,T) \quad (1.8) \\
  u = 0 \quad \text{and } \quad p = 0 \quad \text{on } \Gamma \times (0,T) \quad (1.9) \\
  \zeta(0) &= d_0 \quad \text{in } \Omega, \text{ for } t = 0 \quad (1.10)
\end{align*}
\]

Note that we can write (1.6) equivalently as

\[-\mu \Delta u - (\lambda + \mu) \nabla (\nabla \cdot u) + \alpha \nabla p = F,
\]

where the Laplacian above is interpreted component-wise.

**Assumption 1.1.** [Assumptions on the Permeability Function] We assume that the permeability function \( k : \mathbb{R} \to \mathbb{R} \) is continuous and that there exist constants \( k_1 > 0 \) and \( k_2 > 0 \) s.t.

\[0 < k_1 \leq k(x) \leq k_2, \quad \forall x \in \mathbb{R}.
\]

With a slight abuse of notation, we denote by \( k(\Psi(\cdot,t)) \) the Nemytskii operator associated with \( k \). Using our assumptions on the function \( k \), and the theory of superposition operators \cite{18,23}, we have that the operator \( k \) is bounded and continuous from \( L^2(\Omega \times (0,T)) \) into \( L^2(\Omega \times (0,T)) \).

**Remark 1.2.** In order to obtain uniqueness of solution in Section 6 we will further assume that \( k \) is a globally Lipschitz function, i.e., \( k \in \text{Lip}(\mathbb{R}) \).

**Assumption 1.2.** In what follows, for simplicity, we set to unity non-essential (from the mathematical point of view) parameters. This is to say, we take \( \lambda_e = \mu_e = \alpha = 1 \). The parameter \( c_0 \) is retained, with no dependence on the other parameters, as we will consider taking \( c_0 \searrow 0 \) in the construction of weak solutions for the case of incompressible constituents.
2 Main Results

2.1 Notation, Function Spaces, and Conventions

We make the following conventions for the rest of the paper. Norms $\| \cdot \|_D$ are taken to be $L^2(D)$ for a domain $D$. Inner products in $L^2(D)$ are written as $\langle \cdot, \cdot \rangle_D$, where the subscript will be omitted when the context is clear. The standard Sobolev space of order $s$ defined on a domain $D$ \cite{[14]} will be denoted by $H^s(D)$, with $H^0_0(D)$ denoting the closure of $C_0^\infty(D)$ in the $H^s(D)$ norm (which we denote by $\| \cdot \|_{H^s(D)}$ or $\| \cdot \|_s$). Vector valued spaces will be denoted as $L^2(\Omega)^n$ and $H^s(\Omega)^n$. We make use of the standard notation for the trace of functions $\gamma: H^1(D) \to H^{1/2}(\partial D)$ which generalizes restriction to a lower dimensional manifold. We will make use of the spaces $L^2(0,T;U)$ and $H^s(0,T;U)$, where $U$ is a topological vector space. These norms (and associated inner products) will be denoted with the appropriate subscript, e.g., $\| \cdot \|_{L^2(0,T;U)}$. We utilize the Frobenius scalar product for tensors with the Einstein summation convention:

$$\langle A, B \rangle = \int_\Omega (A_{ij}B_{ij}) d\Omega,$$

sometimes also denoted by $\int_\Omega A : B \ d\Omega$. Notice that, when $A = B$, we write

$$\langle A, A \rangle = \int_\Omega A : A \ d\Omega = \sum_{i,j} (A_{ij}, A_{ij}) = \|A\|^2,$$

the latter norm taken in the Frobenius sense.

The primary spaces in our analysis below are

$$V \equiv H^1_0(\Omega), \quad \hat{V} \equiv (H^1_0(\Omega))^3,$$

for the pressure $p$ and elastic displacement from equilibrium $u$, respectively. The norms in these spaces are taken in the natural sense, respectively, accounting for Poincaré’s and Korn’s inequalities \cite{[14]}. For $V$, we take the gradient norm (as is standard on $H^1_0(\Omega)$): $\|v\|_V = ||v||_{H^1_0(\Omega)} = \|\nabla v\|_{L^2(\Omega)}$.

We will frequently need to denote the duality pairing between $V$ and $V'$ or $\hat{V}$ and $\hat{V}'$, for which we will use the generic notation $\langle \cdot, \cdot \rangle$. (For more general spaces $B$ and $B'$, we may write $\langle \cdot, \cdot \rangle_{B' \times B}$ for clarity.)

We utilize the notation $\nabla u$ as the Jacobian matrix of $u$ and the associated symmetric gradient $\varepsilon(u)$, yielding the following definitions and formal identities:

$$\nabla u = (\partial_j u^i), \quad \nabla u^T = (\partial_i u^j); \quad \varepsilon(u) = \frac{1}{2}[\nabla u + \nabla u^T]$$

$$\langle \nabla u, \nabla w \rangle_\Omega = \int_\Omega [\nabla u : \nabla w] dx = tr(\nabla u \nabla w^T) = tr(\nabla w^T \nabla u) = (\nabla w^T, \nabla u^T)$$

$$\langle \varepsilon(u), \nabla w \rangle = \frac{1}{2}(\nabla u, \nabla w) + \frac{1}{2}(\nabla u^T, \nabla w) = \langle \varepsilon(u), \varepsilon(w) \rangle.$$  

In the simplified setting, the bilinear form associated with the elasticity operator is given by

$$a(u, w) = (\nabla \cdot u, \nabla \cdot w) + (\nabla u, \nabla w) + (\nabla u, \nabla w^T).$$

We topologize the space $\hat{V}$ via $a(\cdot, \cdot)$, which is to say that we take the norm induced by $a(\cdot, \cdot)$ as the norm on $\hat{V}$, and, via Korn’s inequality and Poincaré, this is equivalent to the full $H^1(\Omega)$ norm on $\hat{V}$ \cite{[14]}, as in \cite{[4,6]}.
In our estimates below, we utilize the notation of $Q_1 \lesssim Q_2$ to indicate that there is a constant $C$ depending only on non-critical quantities such that $Q_1 \leq CQ_2$. In general, throughout the paper the quantity $C$ represents a generic constant that may change from line to line. If a constant exhibits a critical dependence, this will be denoted with subscripts or in parentheses, for instance: $\|f\| \leq C_\varepsilon \|g\|$ or $A = A(\Omega)$.

Finally, in this analysis we assume that the principal domain $\Omega$ is of class $C^2$ [8,14], so that standard elliptic regularity results apply.

2.2 Weak Solutions

As one can see in [6,15,20], for instance, there are many different notions of strong and weak solution to poroelastic systems. Our notion of solution is consistent with the classical one provided in [25] in the sense that the solution satisfies a weak space-time form of (1.6)–(1.10). Moreover, our weak solutions are in line with the general notion of weak solution for the time-dependent linear problem holding in the dual sense (in $L^2(0,T;V')$), as presented [19].

Definition 1 (Weak solutions). A solution to (1.6)–(1.10) with $c_0 \geq 0$ is represented by the pair of functions

$$u \in L^2(0,T;V) \quad \text{and} \quad p \in L^2(0,T;V'),$$

with $\zeta = c_0p + \nabla \cdot u \in L^2(0,T;L^2(\Omega))$, such that:

(a) the following variational forms are satisfied for any $w \in L^2(0,T;V)$, $q \in L^2(0,T;V)$:

$$\int_0^T a(u,w)dt - \int_0^T (p,\nabla \cdot w)_\Omega dt = \int_0^T (F,w) dt \tag{2.6}$$

$$\int_0^T (k(\zeta)\nabla p,\nabla q)_\Omega dt - \int_0^T (\zeta_t,q)_{V'\times V} dt = \int_0^T (S,q)_{V'\times V} dt \tag{2.7}$$

(b) for every $q \in V$, the term $\langle \zeta(t),q \rangle_{L^2(\Omega)}$ uniquely defines an absolutely continuous function on $[0,T]$ and the initial condition $\langle \zeta(0),q \rangle_{L^2(\Omega)} = \langle d_0,q \rangle_{L^2(\Omega)}$ is satisfied.

Remark 2.1. Alternatively to (b) above, one could assume that $d_0 \in L^2(\Omega)$ but specify that $\zeta \in C([0,T];V')$ and $\zeta(t)|_{t=0} = [c_0p + \nabla \cdot u](t)|_{t=0} = d_0$ in the $H^{-1}(\Omega)$ sense. This is precisely what we will obtain through our constructions.

Remark 2.2. In [4,25], test functions are taken as space-time products, and all terms are defined in terms of spatial $L^2(\Omega)$ inner products. Our formulation is equivalent by density, as the test functions of the form $w(x)f(t)$, with $w \in V$ and $f \in C_0^\infty(0,T)$, are dense in $L^2(0,T;V)$; similarly, test functions of the form $q(x)f(t)$, with $q \in V$ and $f \in C_0^\infty(0,T)$, are dense in $L^2(0,T;V')$.

Remark 2.3. We note finally that the above definition of weak solution could certainly be weakened. For instance, in the weak form of elasticity, the RHS could be replaced by $\int_0^T (F,w)_{V'\times V} dt$ and the initial condition $d_0$ could be taken in $V'$ (being mindful of the previous approaches in [4,6,20]). However, we use Definition 1 based on the regularity required for our construction, predominantly influenced by the presence of nonlinearity in the problem and a careful treatment of the spatial regularity of $\zeta = c_0p + \nabla \cdot u$.

It will be convenient in the estimates below to utilize a notation for “data” associated to a priori estimates obtained in the analysis of the pressure equation (2.7).

Definition 2. [Notion of Data]

$$\text{DATA} \equiv \int_0^T \left[ ||S(t)||^2_{V'} + ||F(t)||^2_V + ||F(t)||^2_{V'} \right] dt \tag{2.8}$$
2.3 Main Results and Comparison to Previous Literature

We begin this section with the statements of our main results, and follow them with an in-depth, technical discussion of our results in relation to the literature. It is important to note the ways in which our contributions here represent alternative proofs for similar results in the literature, and in what ways our approaches here are novel. Indeed, there is a striking amount of subtlety already present in the analysis of the associated linear Biot system.

The first auxiliary result we prove is that of existence of weak solutions to the associated linear problem for a given \(z \in L^2(0; T; L^2(\Omega))\) and permeability \(k(z)\):

\[
\begin{align*}
-\mu \Delta u - (\lambda + \mu)\nabla (\nabla \cdot u) &= -\nabla p + F \quad &\in L^2(0; T; V') \\
\zeta - \nabla \cdot [k(z)\nabla p] &= S \quad &\in L^2(0; T; V') \\
\zeta &= c_0 p + \nabla \cdot u \quad &\in L^2(0; T; L^2(\Omega)) \\
c_0 p(0) + \nabla \cdot w(0) &= d_0 \quad &\in L^2(\Omega).
\end{align*}
\]

**Theorem 2.1 (Linear Weak Solution).** Let \(c_0 > 0\), and assume that the permeability \(k\) satisfies the hypotheses of Assumption 7. Let \(d_0 \in L^2(\Omega)\), \(z \in L^2(0; T; L^2(\Omega))\), \(F \in L^2(0; T; L^2(\Omega)) \cap H^1(0; T; V')\), and \(S \in L^2(0; T; V')\). Then (2.9) has a weak solution \((u(z), p(z), \zeta(z))\), where \(u(z) \in L^2(0; T; H^2(\Omega) \cap V)\), \(p(z) \in L^2(0; T; V)\), and \(\zeta(z) \in L^2(0; T; H^1(\Omega)) \cap H^1(0; T; V')\), with associated estimates:

\[
\begin{align*}
|c_0||p||_{L^\infty(0; T; L^2(\Omega))} + ||p||_{L^2(0; T; V)} &\lesssim ||d_0||_{L^2(\Omega)}^2 + DATA_0^T \\
|u||_{L^2(0; T; H^2(\Omega) \cap V)} &\lesssim ||p||_{L^2(0; T; V)}^2 + ||F||_{L^2(0; T; L^2(\Omega))} \\
||c_0 p + \nabla \cdot u||_{L^2(0; T; V')} &\lesssim ||p||_{L^2(0; T; V)} + ||S||_{L^2(0; T; V')}
\end{align*}
\]

**Remark 2.4.** We note that nothing in the above result (or its corresponding proof) changes if, instead of \(k = k(z)\) we have \(k = k(x, t)\) a given \(L^\infty(0; T; L^\infty(\Omega))\) - function. In this case, it also follows from [19, p.116] that solution is unique if \(k_t \in L^1(0; T; L^\infty(\Omega))\).

Next we present our result for the existence of weak solution to the nonlinear system:

**Theorem 2.2 (Nonlinear Weak Solution).** Consider the nonlinear coupled system (1.6)–(1.10) with \(c_0 \geq 0\), permeability function \(k(\cdot)\) satisfying Assumption 7.7 and distributed sources \(S \in L^2(0; T; V')\) and \(F \in L^2(0; T; L^2(\Omega)) \cap H^1(0; T; V')\). For initial data \(\zeta(0) = d_0 \in L^2(\Omega)\), there exists a weak solution \(u \in L^2(0; T; V)\) and \(p \in L^2(0; T; V)\) in the sense of Definition 7. Moreover, \(c_0 p \in L^\infty(0; T; L^2(\Omega))\) and \(u \in L^2(0; T; H^2(\Omega) \cap V)\), with the same inequalities (2.10)–(2.12) holding for nonlinear weak solutions.

**Remark 2.5.** We note from the estimates above that, in the sense of the pressure equation, the solution is truly “weak.” However, since we have fundamentally elliptic-parabolic coupling, with the regularity assumptions placed on \(F\), the solution is “strong” in the sense of the elastic displacement, since that equation holds a.e. \(x\), a.e. \(t\).

We now address uniqueness of solution through the imposition of additional regularity hypotheses. As the problem is fundamentally quasi-linear in nature, such additional regularity for uniqueness is expected. Our approach to uniqueness is rooted in multiplier estimates, which are themselves problematic for weak solutions. Hence, we need to restrict our attention to the class of weak solutions (for fixed data \(F, S, d_0\), permeability function, and intrinsic parameters) such that the solution can properly be used as a test function. Beyond this, additional spatial regularity will be needed to manipulate the nonlinear permeability term.
Making use of an explicit solver for the embedded Stokes-type problem in the dynamics. In that more recent [15] provides a Galerkin-based construction of solutions for the full Biot problem, a generalized version of Lax-Millgram due to Lions. Lastly, with respect to the linear analysis, the Chapter III.3, a nice time-dependent formulation for weak solutions is presented based on a semigroup theory to obtain both weak and strong solutions. For the weak solutions (what [20, Chapter 6] calls the “holomorphic case”) only specification of the initial fluid content is needed. The implicit semigroup approach does not explicitly depend a priori estimates based on solution multipliers; instead, quotient and seminormed spaces are invoked to reduce the implicit problem to a regular explicit Banach-valued ODE [19, Chapter IV.6]. As such, this general approach is not immediately generalizable to time-dependent or quasilinear cases. We note that in [19, Chapter III.3], a nice time-dependent formulation for weak solutions is presented based on a generalized version of Lax-Millgram due to Lions. Lastly, with respect to the linear analysis, the more recent [15] provides a Galerkin-based construction of solutions for the full Biot problem, making use of an explicit solver for the embedded Stokes-type problem in the dynamics. In that.
work, solutions are clearly constructed without temporal discretization, but strong assumptions are made on the data in order to obtain good a priori estimates.

In the authors’ previous work \cite{4}, the nonlinear problem presented here is addressed with $c_0 = 0$ and allow for the possibility of visco-elastic effects in the Biot structure. Additionally, motivated by physical considerations, a configuration with mixed boundary conditions on a Lipschitz domain, and non-zero boundary sources, is considered. That work is based on full spatio-temporal discretization (adapting the linear argument in \cite{25}). As such we make use of the stronger assumption on initial data in order to obtain good estimates at the temporally discretized level and carefully pass with the limit, invoking compactness in the fluid content derived from a small amount of elliptic regularity. The multipliers approach works here, albeit in the discrete setting, with two subsequent limit passages required. The accompanying estimates are less natural however, and the fully discretized nature is neither optimal nor natural for modern numerical analysis of the nonlinear problem.

In comparison, our goal here is to provide a theory of solutions for the nonlinear poroelastic coupling in \eqref{1.6}--\eqref{1.10}. As mentioned before, we consider a similar model and set of assumptions as the ones used in \cite{6}. However, we permit the case of fluid-solid mixtures which may have incompressible constituents ($c_0 = 0$), with applications to biological tissues. This degeneracy is rather benign at the linear level, but presents subtle challenges for the analysis here, owing to the fact that the operator $B$ is not invertible on $L^2(\Omega)$, but $c_0 I + B$ is. Indeed, we use critically the presence of $c_0 > 0$ to construct solutions, and then produce the solution for $c_0 = 0$ via a singular limit approach as $c_0 \searrow 0$. It is also worthwhile to note that, in line with biological applications, we allow the permeability to depend on the full fluid content, i.e., $k(\zeta)$ for $\zeta = c_0 p + \alpha \cdot u$ (also as in \cite{4}). In \cite{6}, the construction critically requires $c_0 > 0$ \cite[p.1259(line 6), p.1260(line -9)]{6} but there, the permeability depends only on dilation, i.e., $k(\nabla \cdot u)$ \cite[p.1254]{6}; this distinction is mathematically non-trivial.

We present here what we believe to be the most direct and illustrative approach for existence of weak solutions. Our approach does not involve the discretization of the balance equations in both time and space \cite{4,6}. We believe this is beneficial for future considerations, as full discretization is cumbersome for a sought-after construction of smooth solutions, and our semi-discretized approach is perhaps more amenable to numerical treatment. The work in \cite{20} focuses on constant permeability $k$ (which renders a linear coupling in the system) and develops a semigroup theory for implicit evolution equations for both strong and weak solutions. The approach is generalized for the case of nonlinear permeability function dependent on pressure which preserves a monotone structure in \cite{21}. We note that the strategy developed in \cite{20} can not be directly applied here, as the model at hand does not exhibit such monotonicity properties. Rather, we build linear time dependent solutions and carefully construct a functional correspondence that leads to a fixed point. In constructing weak solutions via estimates in a fixed point argument, we hope to have provided a framework for the future construction of smooth solutions, which should be unique, according to the criterion given here.

### 3 Fundamental Operators and Translation of Momentum Source

In this section we introduce the principal operators that are used in the proofs of the main theorems, along with their properties. We follow the abstract framework provided in \cite{20}. In the last part of the section we provide formal “translations” of the linear and nonlinear problems that allow us to consider the problem with null distributed force in the balance of linear momentum, upon translating the initial data and the pressure source $S$. 

3.1 Elasticity Operator $\mathcal{E}$

In general, the elasticity operator associated to isotropic homogenous media is given by

$$-(\lambda_e + \mu_e) \nabla (\nabla \cdot u) - \mu_e \Delta u = -\nabla \cdot [2\mu_e \varepsilon(u) + \lambda_e (\nabla \cdot u)]I.$$ 

Since we have taken $\mu_e = \lambda_e = 1$ here, we consider an operator $\mathcal{E}(u)$, whose action in distribution is given by:

$$\mathcal{E}_0(u) = -\nabla \cdot [2\varepsilon(u) + \nabla \cdot u] = -2\nabla (\nabla \cdot u) - \Delta u.$$ 

From this action, we can create an unbounded operator $\mathcal{E}: L^2(\Omega) \to L^2(\Omega)$ encoding the homogeneous Dirichlet boundary conditions here. This is to say, $\mathcal{E}$ is the operator with domain

$$D(\mathcal{E}) \equiv \{ u \in V : \mathcal{E}_0(u) \in L^2(\Omega) \}.$$ 

(Note that $\mathcal{E}$ considered from $V \to V'$ acts boundedly.) Indeed, $\mathcal{E}$ is an isomorphism $[8,20]$ in the appropriate senses, and the operator $\mathcal{E}: L^2(\Omega) \to L^2(\Omega)$ is positive, self-adjoint associated to the symmetric bilinear form $a(\cdot, \cdot) : V \times V \to \mathbb{R}$.

In the analysis of the momentum equation, we consider a given $p \in L^2(\Omega)$ (and thus $\nabla p \in V'$ $[20,22]$) and produce a corresponding $u \in V$ which satisfies the stationary elasticity equation, which we will frequently write as

$$\mathcal{E}(u) = -\nabla p + F \in V'. \quad (3.1)$$

This leads directly to the following lemma:

**Lemma 3.1.** Given $G \in V'$, we can consider the elasticity problem

$$\begin{cases}
\mathcal{E}(u) = G & \in V' \\
u = 0 & \text{on } \Gamma.
\end{cases} \quad (3.2)$$

This problem is well-posed in the standard weak sense $[8,14]$, with a solution $u \in V$ and stability estimate

$$||u||_V \leq C_w ||G||_{V'}, \quad \forall u \in V.$$ 

Moreover, as $\Omega$ is of class $C^2$, classical elliptic regularity applies $[8,22]$. Hence, if $G \in L^2(\Omega)$, then we have that $u \in H^2(\Omega) \cap V$, and

$$||u||_{H^2(\Omega)} \leq C_r ||G||_{L^2(\Omega)}.$$ 

Unlike [4], we are working with a smooth boundary, composed of a single Dirichlet component upon which both pressure $p$ and displacement $u$ are zero. Thus classic elliptic theory can be used for displacement $u$ when $p \in V$ and $F \in L^2(\Omega)$. When $F = 0$ in (3.1), we have

$$p \in V \implies \nabla p \in L^2(\Omega) \implies \mathcal{E}^{-1}(-\nabla p) = u \in H^2(\Omega) \cap V \implies \nabla \cdot u \in H^1(\Omega). \quad (3.3)$$

Such regularity was not available in [4], where a more complex, physically-motivated boundary configuration was considered.
3.2 Elliptic Operator $A_z$

For a smooth $z \in C^1([0, T] \times \Omega)$, we define the linear operator $A_z : V \to V'$ by

$$A_z p = -\nabla \cdot [k(z) \nabla p], \quad \forall p \in \mathcal{D}(\Omega),$$

(3.4)

where $k(z)$ is interpreted as a Nemitskii operator for the given function $z(x, t)$ as in [11].

**Remark 3.1.** In practice we will consider this operator through its bilinear form (defined below) when $z \in L^2(0, T; L^2(\Omega))$, considered a.e. $t$.

If we assume that $z \in L^2(0, T; H^1(\Omega))$, then we have an unbounded operator $A_z : L^2(\Omega) \to L^2(\Omega)$ with domain $\mathcal{D}(A_z) = H^2(\Omega) \cap V$ and action given by (3.3) with associated bilinear form

$$A[p, q; z] = (k(z) \nabla p, \nabla q), \quad \forall p, q \in V.$$

(3.5)

As noted above, the bilinear form associated to the weak form of $A_z$ requires only that $z \in L^2(0, T; L^2(\Omega))$, and can be obtained via density. When $k \equiv \text{ const}$, $A_z$ is a multiple of the standard Dirichlet Laplacian. In this setting, $A_z$ is a maximal monotone operator, the bilinear form $A[\cdot, \cdot; z]$ continuous and coercive on $V$, and $A_z$ is positive and self-adjoint as an unbounded operator on $L^2(\Omega)$.

3.3 Pressure to Dilation Map

The pressure to dilation map was introduced in the setting of Biot problems in [19, 20]. It allows one to reduce the $(u, p)$ system in (1.6)–(1.10) to an implicit evolution problem, such as those studied extensively in [19, 20]. This operator is a useful, descriptive tool in the construction of approximate solutions, and the subsequent analyses.

Consider the map $B : L^2(\Omega) \to L^2(\Omega)$, defined by

$$Bp = -\nabla \cdot \mathcal{E}^{-1}(\nabla p),$$

(3.6)

motivated by the problem above in (3.2). Indeed, we have that $p \in H^s(\Omega) \implies \nabla p \in H^{s-1}(\Omega)$ with $p \mapsto \nabla p$ continuous in this setting [14][22]. In the specific case when $p \in L^2(\Omega)$, $\nabla p \in H^{-1}(\Omega) = V'$. Invoking the properties of the elliptic operator $\mathcal{E}$, we see that indeed $B \in \mathcal{L}(L^2(\Omega))$.

Similarly, the action of $B$ extends readily to $V$. Considering $B$ as above, if $p \in V$, then as above in (3.3), $Bp \in H^1(\Omega)$. Similarly, we obtain immediately that $B \in \mathcal{L}(H^s(\Omega) \cap V, H^s(\Omega))$ for $s \geq 1$ via the elliptic regularity associated to $\mathcal{E}$. Note that when $F \equiv 0$ in the elasticity equation, as in (3.3) we have $Bp = \nabla \cdot u$.

**Remark 3.2.** Consider $p \in V$, and, as above $Bp = \nabla \cdot u \in H^1(\Omega)$. Although it is not clear that $\nabla \cdot u \in V$, we do know that $Bp = \nabla \cdot [\text{div} V]$, which does carry additional information, in particular that $Bp \in H^1(\Omega) \cap L^2(\Omega)/\mathbb{R}$—see [22].

Based on the discussions above, we have:

**Lemma 3.2.** Given $p \in V$ and $F \in L^2(\Omega)$, the corresponding solver $\mathcal{E}^{-1}(-\nabla p + F) \in H^2(\Omega) \cap V$ with associated continuity bound. When $F \equiv 0$ and $p \in V$, we have $Bp = \nabla \cdot u \in H^1(\Omega)$ for $E(u) = -\nabla p$. From this we obtain that

$$B : H^1_0(\Omega) \to H^1(\Omega), \quad \text{continuously}.$$

\footnote{Let us utilize the standard (abuse) of notation for the quotient space $L^2(\Omega)/\mathbb{R} \equiv \{ f \in L^2(\Omega) : \int_\Omega f = 0.\}$.}
We note some kernel and range properties of the $B$ operator (closely following [20] and utilizing the properties of $\nabla$ and div as in [22]).

**Lemma 3.3.** Considered as a mapping on $H^1_0(\Omega)$, $B$ is injective. Considered as a mapping on $L^2(\Omega)$, $\ker(B) = \{\text{constants}\}$, and hence $B$ is injective on $L^2(\Omega)/\mathbb{R}$.

With respect to ranges, we have the following:

\[
B(L^2(\Omega)) \subseteq L^2(\Omega)/\mathbb{R}, \quad B(H^1_0(\Omega)) \subseteq H^1(\Omega)/\mathbb{R}.
\]

Finally, we have that $B$ is a self-adjoint, monotone operator when considered on $L^2(\Omega)$ [4,20].

**Lemma 3.4.** Considering $B \in \mathcal{L}(L^2(\Omega))$, it is a non-negative, self-adjoint operator.

By the standard construction [9,16], the self-adjoint operator $B^{1/2} \in \mathcal{L}(L^2(\Omega))$ is obtained with characterizing property

\[
(Bp,q)_{L^2(\Omega)} = (B^{1/2}p,B^{1/2}q)_{L^2(\Omega)} = (p,Bq)_{L^2(\Omega)}, \quad \forall \, p,q \in L^2(\Omega).
\]

A central issue in the analysis here is that $B \in \mathcal{L}(L^2(\Omega))$ need not be coercive in that setting. However, in the case where we consider compressible effects, the operator $c_0I + B : L^2(\Omega) \rightarrow L^2(\Omega)$ is coercive. We will use this critically and repeatedly below.

**Corollary 3.5.** Let $c_0 > 0$. Then the operator $c_0I + B : L^2(\Omega) \rightarrow L^2(\Omega)$ is an isomorphism.

**Proof.** By positivity, we note that for $p \in L^2(\Omega)$

\[
([c_0I + B]p,p)_{L^2(\Omega)} = c_0||p||^2 + (Bp,p) \geq c_0||p||^2.
\]

Hence, the operator $c_0I + B$ is coercive on $L^2(\Omega)$. Since $B \in \mathcal{L}(L^2(\Omega))$, surjectivity follows immediately from Lax-Milgram applied to the form

\[
\beta(p,q) = ([c_0I + B]p,q)_{L^2(\Omega)} = c_0(p,q)_{L^2(\Omega)} + (B^{1/2}p,B^{1/2}q)_{L^2(\Omega)}.
\]

Which is to say that

\[
\beta(p,q) = (f,q)_\Omega, \quad \forall q \in L^2(\Omega)
\]

is uniquely solvable with associated stability bound. 

We conclude this section with some rather important additional remarks about the $B$ operator that arise critically in the context of previous approaches to the problem at hand.

- Since $B$ implicitly invokes an elliptic solver, its behaviors on $V'$ or any $H^{-s}(\Omega)$—regularity and continuity properties, kernel and range—are **not** in the realm of standard elliptic theory.

- It is not clear that $B \in \mathcal{L}(H^{-1}(\Omega))$, or that that $B(H^1_0(\Omega)) \subset H^1_0(\Omega)$. Indeed, characterizing the range of $B$ on $V$ involves ranging the divergence operator over $H^1_0(\Omega)$.
3.4 Translation to Eliminate Momentum Source $F$

In this subsection we provide formal “translations” to the linear and nonlinear problems that allow us to consider the problem with $F \equiv 0$. In latter sections, to simplify the analysis, we will operate on the translated problem. After obtaining the principal result in those sections, we will refer to this section and translate back to obtain (linear and nonlinear) results for the original system.

We first note that it is sufficient to solve the linear problem—where $k = k(z)$ for $z \in L^2(0, T; H^2(\Omega))$—with $F \equiv 0$ by a standard translation. Consider

$$
\begin{cases}
\mathcal{E}(u) = -\nabla p & \in L^2(0, T; \mathbf{V}') \\
\zeta_t + A_z p = S & \in L^2(0, T; \mathbf{V}') \\
\zeta = c_0 p + \nabla \cdot u & \in L^2(0, T; L^2(\Omega)) \\
\zeta(0) = d_0 & \in L^2(\Omega)
\end{cases}
$$

(3.7)

Indeed, as the elasticity equation is elliptic and $F \in L^2(0, T; L^2(\Omega))$, for a.e. $t \in [0, T]$ we can simply write

$$
u_F(t) = \mathcal{E}^{-1}(F(t)) \in H^2(\Omega) \cap \mathbf{V}.
$$

(3.8)

Additionally, with the regularity hypotheses of our main theorem $F \in L^2(0, T; L^2(\Omega)) \cap H^1(0, T; \mathbf{V}')$, we have that $u_F \in L^2(0, T; H^2(\Omega) \cap \mathbf{V}) \cap H^1(0, T; \mathbf{V})$. Then, considering the variable $w = u - u_F$, we note that $u$ solves (3.7) if and only if $w$ solves

$$
\begin{cases}
\mathcal{E}(w) = -\nabla p & \in L^2(0, T; \mathbf{V}') \\
c_0 p_t + \nabla \cdot w_t + A_z p = S + \nabla \cdot u_F & \in L^2(0, T; \mathbf{V}') \\
c_0 p(0) + \nabla \cdot w(0) = d_0 - \nabla \cdot u_F(0) & \in L^2(\Omega)
\end{cases}
$$

(3.9)

Hence, by re-scaling $S \in L^2(0, T; \mathbf{V}')$ and $d_0 = \zeta(0) \in L^2(\Omega)$, we obtain an equivalent linear problem for a given $z$ with $F \equiv 0$.

In the case of the nonlinear problem, where $A_z = A_\zeta$ for $\zeta = c_0 p + \nabla \cdot u$, an additional step is needed. We note that if $w = u - u_F$ as above, the fluid content has expression

$$
\zeta = c_0 p + \nabla \cdot u = c_0 p + \nabla \cdot w + \nabla \cdot u_F.
$$

Since $\nabla \cdot u_F \in L^2(0, T; H^1(\Omega)) \cap H^1(0, T; L^2(\Omega))$, we have that $\nabla \cdot u_F \in C([0, T]; L^2(\Omega))$ \cite{13, 19}. Hence, for any $k(\cdot)$ as in \cite{19}, we introduce the function $k_F(\cdot) \in C(\mathbb{R})$ representing the $u_F$-translate of $k(\cdot)$, namely

$$
k_F(\cdot) = k(\cdot + \nabla \cdot u_F).
$$

(3.10)

Since $k(\cdot)$ satisfies \cite{19} we obtain immediately that $k_F(\cdot)$ satisfies the assumption as well. Then, from the (abstract) strong form of the original problem,

$$
\begin{cases}
\mathcal{E}(u) = -\nabla p + F & \in L^2(0, T; \mathbf{V}') \\
\zeta_t - \nabla \cdot [k(\zeta) \nabla p] = S & \in L^2(0, T; \mathbf{V}') \\
\zeta = c_0 p + \nabla \cdot u & \in L^2(0, T; L^2(\Omega)) \\
c_0 p(0) + \nabla \cdot u(0) = d_0 & \in L^2(\Omega),
\end{cases}
$$

(3.11)

we can write the system for $w = u - u_F$ as follows

$$
\begin{cases}
\mathcal{E}(w) = -\nabla p & \in L^2(0, T; \mathbf{V}') \\
(c_0 p + \nabla \cdot w)_t - \nabla \cdot [k_F(c_0 p + \nabla \cdot w) \nabla p] = S + \nabla \cdot u_F & \in L^2(0, T; \mathbf{V}'),
\end{cases}
$$

(3.12)
As in the linear case, for a fixed $F$ and $k$, by re-scaling $S$ and $d_0$ accordingly, and re-labeling $k \mapsto k_F$, we again obtain an equivalent problem with $F = 0$.

### 4 Existence of Solutions for the Linear Problem

In this section we present the proof of Theorem 2.1.

Recall that we explicitly assume that $c_0 > 0$. In line with the translation introduced in Section 3.4, we consider the problem with $F \equiv 0$. Moreover, we retain the names for the datum $d_0 \in L^2(\Omega)$ and source $S \in L^2(0, T; V')$ (after up dating them, as discussed in the previous section). Thus we consider the linear problem (3.7) for a given $z \in L^2(0, T; V)$, as was done in [6, 20] as the (implicit) initial boundary value problem

\[
\begin{aligned}
\left( (c_0 I + B)p \right)'_{t} - \nabla \cdot (k(z) \nabla p) &= S, & \quad & \Omega \times (0, T) \\
p &= 0, & \quad & \Gamma \times (0, T) \\
(c_0 I + B)p(0) &= d_0, & \quad & \Omega 
\end{aligned}
\]  

(4.1)

Recall that for $z \in L^2(0, T; L^2(\Omega))$, we defined the bilinear form

\[A[\cdot, \cdot; z] : V \times V \to \mathbb{R} \text{ by } A[p, q; z] = (k(z) \nabla p, \nabla q)_{\Omega}.\]  

(4.2)

Due to Assumption 1.1 on the permeability operator $k$, the following Proposition is immediate.

**Proposition 4.1.** The bilinear form $A[\cdot, \cdot; z]$ satisfies the following properties:

1. **Continuity:** $\exists M > 0$ s.t. $|A(w_1, w_2; z)| \leq M
\|w_1\|_V \|w_2\|_V$, \ $\forall w_1, w_2 \in V$, a.e. in $[0, T]$.

2. **Coercivity:** $A(w, w; z) \geq k_1 \|w\|^2_V$, for all $w \in V$.

Let us clearly state a weak formulation for (4.1) above. In the remaining part of this section, the notation $f'$ will denote differentiation in time, and recall the angle brackets represent the duality pairing between $V'$ and $V$, i.e., $\langle \phi, g \rangle = \phi(g) = \langle \phi, g \rangle_{V' \times V}$.

**Definition 4.** Given $z \in L^2(0, T; L^2(\Omega))$, we say that $p \in L^2(0, T; V)$ with $(c_0 I + B)p \in L^2(0, T; H^1(\Omega))$ and $((c_0 + B)p)' \in L^2(0, T; V')$ is a weak solution for (4.1) provided that

1. For every $q \in L^2(0, T; V)$,

\[
\int_0^T \langle [(c_0 I + B)p]'(t), q(t) \rangle \, dt + \int_0^T A[p(t), q(t); z(t)] \, dt = \int_0^T \langle S(t), q(t) \rangle \, dt
\]  

(4.3)

2. $[(c_0 I + B)p](0) = d_0$ in the sense of $V'$.

Note that since $(c_0 I + B)p \in L^2(0, T; H^1(\Omega))$ and $[(c_0 I + B)p]' \in L^2(0, T; V')$, we have that $(c_0 I + B)p \in C([0, T]; V')$ and thus the initial condition makes sense in $V'$.
Remark 4.1. With regard to the initial condition, although we only identify the initial condition in the sense of $V'$ (as is consistent with the general weak formulation for implicit equations) we also need $d_0 \in L^2(\Omega)$ for the construction at hand. Secondly, we note that it is nearly the case that $[c_0I+B]p$ is a continuous function in time into $L^2(\Omega)$, but since we do not know that $[c_0I+B]p \in V$, we cannot use the standard result \[13\] to obtain that fact.

Remark 4.2. Sometimes it is convenient to work with the following equivalent variational formulation for \[4.3\]:

$$
\langle [(c_0 I + B)p', q] + A[p, q; z] = \langle S, q \rangle, \text{ for each } q \in V \text{ and a.e. time } t \in [0, T]. \quad (4.4)
$$

We note that the real-valued function $t \mapsto \langle [(c_0 I + B)p', q] \rangle$ belongs to $L^1_{loc}(0, T) \subset D'((0, T)$, and Bochner’s theorem yields

$$
\langle [(c_0 I + B)p', q] = \frac{d}{dt} \langle [c_0 I + B]p(t), q \rangle_{\Omega} \in D'(0, T).
$$

Therefore \[4.4\] can be simply written in the form

$$
\frac{d}{dt} \langle [c_0 I + B]p(t), q \rangle_{\Omega} + A[p, q; z] = \langle S, q \rangle, \text{ in } D'(0, T), \text{ for all } q \in V.
$$

Now, let us construct a weak solution as in Definition \[4\] to the reduced problem described above in \[4.1\]. We state this as a lemma, as it will be used in the proof of Theorem \[2.2\].

**Lemma 4.2.** Let $z \in L^2(0, T; L^2(\Omega))$, $S \in L^2(0, T; V')$ and $d_0 \in L^2(\Omega)$. Then \[4.1\] has weak solution, according to Definition \[4\].

**Proof.** Construction of Approximate Solution: We use Galerkin approximations. Let $\{w_k(x)\}_{k=1}^{\infty}$ be an orthogonal basis of $V$, and an orthonormal basis in $L^2(\Omega)$. (For example, we can take $\{w_k(x)\}_{k=1}^{\infty}$ to be the complete set of appropriately normalized eigenfunctions for $-\Delta$ in $V$.) Let $V_n = \text{span}\{w_1, ..., w_n\}$. Note that $V_n$ satisfies the conditions $V_n \subset V_{n+1}$ and $V/V_n = V$. We look for solutions of the form:

$$
p_n(t) = \sum_{k=1}^{n} d_n^k(t)w_k, \quad (4.5)
$$

where the coefficients $d_n^k(t) \in H^1(0, T)$ for $k = 1, ..., n$. Thus we consider the following finite dimensional problem on $V_n$:

Determine $p_n \in H^1(0, T; V)$ such that for every $k = 1, 2, ..., n$,

$$
\begin{cases}
\langle [c_0 I + B]p_n', w_k \rangle_{L^2(\Omega)} + A[p_n, w_k; z] = \langle S, w_k \rangle, & \text{a.e. in } (0, T), \\
d_n^k(0) = ([c_0 I + B]^{-1}d_0, w_k)_{\Omega}, & k = 1, 2, ..., n.
\end{cases} \quad (4.6)
$$

If the differential equation in \[4.6\] holds for each element of the basis $w_k$, with $k = 1, 2, ..., n$, then it also holds for every $w \in V_n$. Moreover, since $[c_0 I + B]p_n' \in L^2(0, T; L^2(\Omega))$, we have from Remark \[4.2\]

$$
\langle [c_0 I + B]p_n'(t), w \rangle_{\Omega} = \langle [c_0 I + B]p_n'(t), w \rangle
$$

Upon expanding $p_n$, \[4.6\] becomes

$$
\begin{cases}
M(d_n^k(t))' + \sum_{k=1}^{n} A[w_k, w_k; z(t)]d_n^k(t) = S^k(t), \\
d_n^k(0) = ([c_0 I + B]^{-1}d_0, w_k), \quad k = 1, 2, ..., n,
\end{cases} \quad (4.7)
$$

\[15\]
where  
\[ M = ([c_0 I + B]w_k, w_k)_{\Omega}, \text{ and } S^k(t) = \langle S(t), w_k \rangle, \quad k = 1, 2, \ldots, n. \]

Since \((c_0 I + B)\) is invertible on \(L^2(\Omega)\), we have that \([([c_0 I + B]w_k)_{k=1}^\infty\) is linearly independent in \(L^2(\Omega)\). Therefore we can find a permutation \(\alpha(i)\) of the basis \(\{w_k\}\) such that for all \(m \in \mathbb{N}\), the matrix \(\{(c_0 I + B)[w_{\alpha(i)}]_{\Omega} \}_{i,j=1}^m\) is nonsingular (see Lemma 2.3 in [15]).

**Remark 4.3.** We note here that in order to construct solutions invoking ODE theory and obtain the subsequent energy estimates below, we require the initial condition \(d_0 \in L^2(\Omega); \) if \(d_0 \in V'\), additional information about the continuity, adjoint, and invertibility of \(B\) on \(V'\) would be needed.

By standard existence theory for ordinary differential equations, there exists a unique, absolutely continuous function \(d_n(t) = [d_n^k(t)]_{k=1}^m\) that solves (4.7). Therefore \(p_n(t) \in H^1(0, T; V)\) defined in (4.5) is a solution for (4.6) for a.e. \(t \in [0, T]\).

**Energy Estimates:** We can interpret (4.3) a.e. \(s \in [0, T]\) and let \(q = p_n \in H^1(0, T; V)\) in (4.3) to obtain
\[
\langle [c_0 I + B]p'_n(s), p_n(s) \rangle + A[p_n(s), p_n(s); z(s)] = \langle S(s), p_n(s) \rangle
\]

Due to the fact that \(B\) is self-adjoint on \(L^2(\Omega)\) and \(p_n(t) \in H^1(0, T; V)\), we have that
\[
\langle [c_0 I + B]p'_n(s), p_n(s) \rangle = \frac{1}{2} \frac{d}{ds} \langle [c_0 I + B]p_n(s), p_n(s) \rangle_{\Omega}
\]

Moreover, with \(k_1\) as the lower bound on \(k\), i.e., the coercivity parameter for \(A\) in Remark (4.1), we have
\[
|\langle S(s), p_n(s) \rangle| \leq \frac{1}{2k_1} ||S(s)||_V^2, + \frac{k_1}{2} ||p_n(s)||_V^2
\]

Thus, with the coercivity assumed in Remark (4.1), we obtain
\[
\frac{1}{2} \frac{d}{ds} \langle [c_0 I + B]p_n(s), p_n(s) \rangle_{\Omega} + \frac{k_1}{2} ||p_n(s)||_V^2 \leq \frac{1}{2k_1} ||S(s)||_V^2
\]

We integrate over \((0, t)\) and obtain
\[
\langle [c_0 I + B]p_n(t), p_n(t) \rangle_{\Omega} + k_1 \int_0^t ||p_n(s)||_V^2 \, ds \leq \langle [c_0 I + B]p_n(0), p_n(0) \rangle_{L^2(\Omega)} + \frac{1}{k_1} \int_0^t ||S(s)||_V^2, \, ds
\]

Using the properties of the operator \(B\) and \(B^{1/2}\) (as in Lemma 6.4 and the discussion following it), we obtain from this estimates point wise (in time) control of \(||p_n(t)||_{L^2(\Omega)}\) and \(||B^{1/2}p_n(t)||_{L^2(\Omega)}\) for each \(t \in [0, T]\), as well as
\[
p_n, \quad B^{1/2}p_n, \quad \langle c_0 + B \rangle^{1/2}p_n \in L^\infty(0, T; L^2(\Omega)), \quad p_n \in L^2(0, T; V).
\]

Thus
\[
||p_n||_{L^\infty(0, T; L^2(\Omega))}^2 + ||B^{1/2}p||_{L^\infty(0, T; L^2(\Omega))}^2 \leq (d_0, ([c_0 I + B]^{-1}d_0)_\Omega) + \frac{1}{k_1} \int_0^t ||S(s)||_V^2, \, ds
\]

and
\[
||p_n||_{L^2(0, T; V)}^2 \leq (d_0, [c_0 I + B]^{-1}d_0)_\Omega + \frac{1}{k_1} \int_0^t ||S(s)||_V^2, \, ds
\]
Since $B$ is continuous from $V$ into $H^1(\Omega)$, we obtain that $Bp_n \in L^2(0,T;H^1(\Omega))$, and thus we have
\[
\| (c_0 I + B)p_n(t) \|_{L^2(0,T;H^1(\Omega))} \leq C \| p_n(t) \|_{L^2(0,T;V)} \tag{4.8}
\]

Now, directly from the \ref{4.1}, using the characterization of the norm in $V' = H^{-1}(\Omega)$, we obtain
\[
\| [(c_0 I + B)p_n]'(s) \|_{V'} \leq M \| p_n(s) \|_V + \| S(s) \|_{V'},
\]
which implies that
\[
[(c_0 I + B)p_n]' \in L^2(0,T;V')
\]
with
\[
\int_0^t \| [(c_0 I + B)p_n]'(s) \|_{V'}^2 \leq 2M^2 \int_0^t \| p_n(s) \|_V^2 + \int_0^t \| S(s) \|_{V'}^2 \leq (d, [c_0 I + B]^{-1} d)_\Omega + \int_0^t \| S(s) \|_V^2.
\]

**Existence:** Since $\{p_n\}$ is bounded in $L^2(0,T;V)$, we can extract a weakly convergent subsequence $p_{n_k}$. If we call the weak limit $p$, then we have that
\[
p_{n_k} \rightharpoonup p \text{ in } L^2(0,T;V) \tag{4.9}
\]
Using the continuity of the operator $B : V \rightarrow H^1(\Omega)$, we obtain that
\[
(c_0 I + B)p_{n_k} \rightarrow (c_0 I + B)p \text{ in } L^2(0,T;H^1(\Omega)) \tag{4.10}
\]
According to the energy estimates above, we have that the subsequence $\{[(c_0 + B)p_{n_k}]'\}$ is bounded in $L^2(0,T;V')$. Consequently, we obtain on a new subsequence (retaining the subscript $n_k$) that
\[
[(c_0 + B)p_{n_k}]' \rightarrow [(c_0 + B)p]' \text{ in } L^2(0,T;V') \tag{4.11}
\]
Now invoking \ref{4.12}, we can write
\[
\int_0^T \langle [(c_0 I + B)p_{n_k}]'(t), q(t) \rangle dt + \int_0^T A[p_{n_k}(t), q(t); z(t)] dt = \int_0^T \langle S, q \rangle dt \tag{4.12}
\]
for every $q \in L^2(0,T;V_{n_k})$. Choose $N$ such that $N = n_k$. In \ref{4.12}, let $q = w \varphi$, with $w \in V_N$ and $\varphi \in \mathcal{D}(0,T)$, and let $n_k \rightarrow \infty$. Thanks to \ref{4.9} and \ref{4.11} and the continuity of the bilinear form $A$ we infer that
\[
\int_0^T \left\{ \langle [(c_0 I + B)p]'(t), w \rangle + A[p(t), w; z(t)] - \langle S(t), w \rangle \right\} \varphi(t) dt = 0 \tag{4.13}
\]
Letting $N \rightarrow \infty$ and using the fact that $\varphi$ is arbitrary, we obtain that
\[
\langle [(c_0 I + B)p]'(t), w \rangle + A[p(t), w; z(t)] = \langle S(t), w \rangle, \text{ for a.e. } t \in (0,T), \text{ and for all } w \in V,
\]
from which \ref{4.13} follows.

It remains to check that $p$ satisfies the initial condition $[c_0 I + B]p(0) = d_0$. We use \ref{4.13} with $\varphi \in C^1([0,T])$ that satisfies $\varphi(0) = 1$ and $\varphi(T) = 0$, and integrate by parts in the first term. We obtain
\[
\int_0^T \left\{ - \langle [c_0 I + B]p(t), w \rangle \Omega \varphi'(t) + A[p(t), w; z(t)] \varphi(t) - \langle S(t), w \rangle \varphi(t) \right\} dt = \langle [c_0 I + B]p(0), w \rangle \Omega \tag{4.14}
\]
Similarly, we use \( q(t) = \varphi(t)w \) with \( w \in V_n \) in (4.12), and integrate by parts in the first term. We obtain

\[
\int_0^T \left\{ -([c_0 I + B]p_{n_k}(t), w)_{\Omega} \varphi'(t) + A[p_{n_k}(t), w; z(t)]\varphi(t) - \langle S(t), w \rangle \varphi(t) \right\} dt = ([c_0 I + B]p_{n_k}(0), w)_{\Omega} \tag{4.15}
\]

If we let \( n_k \to \infty \) in (4.15), the LHS converges to the LHS of (4.14) due to (4.10), and the RHS \( ([c_0 I + B]p_{n_k}(0), w)_{\Omega} \to (d_0, w)_{\Omega} \). Therefore we obtain that \( ([c_0 I + B]p(0), w)_{\Omega} = (d_0, w)_{\Omega} \), and using the density of \( V \) into \( \Omega \) we have that \( [c_0 I + B]p(0) = d_0 \) as desired.

Finally, we also note that from (4.10) and (4.11) we obtain that

\[
(c_0 I + B)p_{n_k} \to (c_0 I + B)p \text{ in } L^2(0, T; L^2(\Omega)) \tag{4.16}
\]

Note that, through the limit point construction, we obtain the estimates below on the constructed solutions by the weak lower semicontinuity of the norm.

**Corollary 4.3.** The weak solution constructed in Lemma 4.2 satisfies for a.e. \( t \in [0, T] \) the estimates

\[
ic_0|p(t)|_{L^2(\Omega)}^2 + ||B^{1/2}p(t)||_{L^2(\Omega)}^2 + ||p||_{L^2(0,T;V')}^2 \lesssim ||d_0||_{L^2(\Omega)}^2 + ||S||_{L^2(0,T;V')}^2 
\]

\[
||([c_0 I + B]p)'||_{L^2(0,T;V')} \lesssim ||p||_{L^2(0,T;V')} + ||S||_{L^2(0,T;V')} \tag{4.18}
\]

\[
||(c_0 I + B)p||_{L^2(0,T;H^1(\Omega))} \lesssim ||p||_{L^2(0,T;V')} \tag{4.19}
\]

We are now in position to conclude the proof of Theorem 2.1.

**Proof of Theorem 2.1.** Given the lemma above, for a given \( z \in L^2(0, T; L^2(\Omega)) \), we have obtained the functions

\[
p(z) \in L^2(0, T; V), \quad \zeta(z) = c_0 p(z) + B p(z) \in L^2(0, T; H^1(\Omega)),
\]

where we have denoted the dependence of the solution on the given function \( z \). Since \( \nabla p(z) \in L^2(\Omega) \) a.e. \( t \), we can invoke the elasticity isomorphism as in Section 3.1 to obtain

\[
\mathbf{u}(z) = \mathcal{E}^{-1}(-\nabla[p(z)]) \in H^2(\Omega) \cap V, \text{ a.e. } t.
\]

By the injectivity of \( B \) on \( V = H^1_0(\Omega) \), we can identify \( B[p(z)] = \nabla \cdot [\mathbf{u}(z)] \) as in (3.7). Hence, we obtain a solution to (3.7).

Finally, with the hypotheses on \( F \) and \( d_0 \), we can translate back to the original case as in (3.9) to immediately obtain a weak solution for

\[
\begin{cases}
\mathcal{E}(\mathbf{u}) = -\nabla p + F & \in L^2(0, T; V') \\
\zeta - \nabla \cdot [k(z) \nabla p] = S & \in L^2(0, T; V') \\
\zeta = c_0 p + \nabla \cdot \mathbf{u} & \in L^2(0, T; L^2(\Omega)) \\
c_0 p(0) + \nabla \cdot \mathbf{u}(0) = d_0 & \in L^2(\Omega).
\end{cases} \tag{4.20}
\]
5 Nonlinear Problem - Existence of Solutions

This section contains the proof of Theorem 2.2. We divide the proof into two parts. First, we focus on the case of compressible constituents, i.e., $c_0 > 0$. Our strategy in this scenario is to show that the map $z \mapsto \zeta$ provided by Theorem 2.1 has a fixed point. In part two of the proof, we obtain existence of solutions for the case of incompressible mixture constituents using a limiting process $c_0 \to 0$.

5.1 Proof of Theorem 2.2 for $c_0 > 0$

We begin by considering the general translated problem with $F \equiv 0$. By Theorem 2.1, given $z \in L^2(0, T; L^2(\Omega))$, the problem (3.7) (with associated regularity of data) has a weak solution, written as $(u(z), \zeta(z), p(z))$, satisfying the estimates in (4.17)–(4.19). We note that since the solution to the linear problem provided by Theorem 2.1 is not necessarily shown to be unique, we must allow the possibility that the solution mapping is multi-valued (in the sense of the Appendix 7). Thus we consider the reduced problem

$$
\begin{aligned}
\zeta_t - \nabla \cdot [k(z)\nabla p] &= S & \in L^2(0, T; V') \\
\zeta &= c_0 p + Bp & \in L^2(0, T; L^2(\Omega)) \\
\zeta(0) &= d_0 & \in L^2(\Omega),
\end{aligned}
$$

(5.1)

and define a correspondence between the given permeability argument $z \in L^2(0, T; L^2(\Omega))$ and the resulting fluid contents $\zeta$ taken from weak solutions (in the sense of Definition 4) corresponding to given $z$ satisfying the a priori estimates in (4.17)–(4.19).

Definition 5. For fixed “data” $d_0$ and $S$ as above, and given $z \in L^2(0, T; L^2(\Omega))$, we define the correspondence

$$
\mathscr{F} : L^2(0, T; L^2(\Omega)) \to L^2(0, T; L^2(\Omega)),
$$

by

$$
\mathscr{F}(z) = \{ \zeta = [c_0 I + B]p : (p, \zeta) \text{ is a weak solution of (5.1) that satisfies (4.17)–(4.19)} \}.
$$

Clearly, using Lemma 4.2 and Corollary 4.3 we have that the set $\mathscr{F}(z) \neq \emptyset$. Moreover, the fact that the range of the correspondence $R(\mathscr{F}) \subseteq L^2(0, T; L^2(\Omega))$ is immediate, since all the elements in the set $p(z)$ belong to $L^2(0, T; L^2(\Omega))$ trivially, and hence by the boundedness of $B \in \mathcal{L}(L^2(\Omega))$ we have that

$$
[c_0 I + B]p \in L^2(0, T; L^2(\Omega)), \quad \forall p \in p(z).
$$

Note here that by the definition of the correspondence, the satisfaction of the initial condition is included in the definition of $\mathscr{F}$. Also, note that passing between a $\zeta(z)$ and a $p(z)$ simply uses the invertibility of $[c_0 I + B]$ on $L^2(0, T; L^2(\Omega))$, as in Corollary 3.5.

We will use the Bohnenblust-Karlin Fixed Point Theorem for correspondences [1] to obtain the existence of (at least) one fixed point for $\mathscr{F}$. The statement of the theorem, along with the relevant background definitions can be found in the Appendix 7. We have the following theorem:

Theorem 5.1. The correspondence $\mathscr{F} : L^2(0, T; L^2(\Omega)) \to L^2(0, T; L^2(\Omega))$ defined above has a fixed point. The set of fixed points of $\mathscr{F}$ is compact in $L^2(0, T; L^2(\Omega))$. 

Proof of Theorem 5.1. Let $d_0 \in L^2(\Omega)$ and $S \in L^2(0,T;V')$ be given. We consider the correspondence $\mathcal{F} : L^2(0,T;L^2(\Omega)) \to L^2(0,T;L^2(\Omega))$ defined above in Definition 4. By the construction of linear solutions as given in Lemma 4.2 and the corresponding estimates in Corollary 4.3 we have that for each $z \in L^2(0,T;L^2(\Omega))$, the set $\mathcal{F}(z) \neq \emptyset$. Moreover, for each element $\zeta \in \mathcal{F}(z)$, via 4.2 we have that

$$\zeta \in L^2(0,T;V), \quad \text{and} \quad \zeta_t \in L^2(0,T;V'),$$

with associated estimates in (4.17)–(4.19).

Step I. First, we show that the correspondence is convex- and closed-valued, i.e., $\mathcal{F}(z)$ is convex and closed, for each $z \in L^2(0,T;L^2(\Omega))$. Thus let $z \in L^2(0,T;L^2(\Omega))$ and let $\zeta_1, \zeta_2 \in \mathcal{F}(z)$. This means that the pairs $(p_i, \zeta_i = [c_0 I + B] p_i)$ satisfy the definition provided in Definition 4 for $i = 1, 2$, namely for every $q \in L^2(0,T;V)$, we have

$$\int_0^T \langle \{c_0 I + B\} p_i(t), q(t) \rangle \, dt + \int_0^T A[p_i(t), q(t); z(t)] \, dt = \int_0^T \langle S(t), q(t) \rangle \, dt$$

and $[(c_0 I + B)p_i](0) = d_0$.

Since the problem is linear in $k(z)$ with $A[p, q; z] = (k(z) \nabla p, \nabla q)_{\Omega}$, convexity in the weak form of solutions and initial conditions is immediate by taking the appropriate linear combination of the above equalities. For the associated inequalities in (4.17)–(4.19), the convexity of norms is sufficient. Indeed, we show this for (4.17): Suppose for $p_i(z), i = 1, 2$ we have:

$$c_0 \|p_i(z)\|^2_{L^\infty(0,T;L^2(\Omega))} + \|B^{1/2} p_i(z)\|^2_{L^\infty(0,T;L^2(\Omega))} + \|p_i(z)\|_{L^2(0,T;V)}^2 \leq C[\|d_0\|^2_{L^2(\Omega)} + ||S||^2_{L^2(0,T;V')}].$$

Then

$$\|\alpha p_1 + (1 - \alpha) p_2\|^2 \leq \alpha \|p_1\|^2 + (1 - \alpha) \|p_2\|^2,$$

and hence by multiplying the inequality (5.3) by $\alpha$ when $i = 1$, and again multiplying by $(1 - \alpha)$ when $i = 2$, then adding the results, yields that the function $\alpha p_1 + (1 - \alpha)p_2$ satisfies (2.10) for any $\alpha \in [0,1]$ with the same constant $C$ associated to the RHS.

To show that $\mathcal{F}(z)$ is closed, consider a sequence $\zeta_n \in \mathcal{F}(z)$ such that $\zeta_n \to \zeta \in L^2(0,T;L^2(\Omega))$. Using the invertibility of the linear operator $c_0 I + B$ on $L^2(0,T;L^2(\Omega))$, we have that $p_n \to (c_0 I + B)^{-1} \zeta_n \in L^2(0,T;L^2(\Omega))$, so we let $p = (c_0 I + B)^{-1} \zeta \in L^2(0,T;L^2(\Omega))$. Since the pair $(p_n, \zeta_n)$ satisfies the estimates (4.17)–(4.19), we know that $p_n$ is uniformly-in-$n$ bounded in $L^2(0,T;V)$. Therefore $p_n$ has a weakly convergent subsequence, whose limit is identified with $p$ by uniqueness of limits. This yields that $p$ lies in $L^2(0,T;V)$.

Passing to the limit, then, in the weak form in (4) is immediate, since the problem is linear in $k(z)$. The estimates in (4.17)–(4.19) on $p(z)$ and $\zeta(z) = [c_0 I + B] p(z)$ follow from weak lower semicontinuity of norms, since each $(p_n, \zeta_n)$ satisfies them by hypothesis. Lastly, obtaining the initial condition is immediate, since each $\zeta_n$ corresponds to a solution with the same initial condition $\zeta_n(t = 0) = d_0$. The estimates on solutions in (4.17)–(4.19) ensure that $\zeta_n, \zeta \in H^1(0,T;V')$, and hence we have that $\zeta(t = 0) = d_0$ as the limit point of $\zeta_n(0)$ (in the sense of $V'$).

Step II. Next, we show the sequential criterion for UHC of the correspondence $\mathcal{F}$, as in Theorem 4.3. To that end, let $\{ (z_n, \zeta_n) \} \subseteq \mathcal{F}(\mathcal{F})$. Suppose further that $z_n \to z \in L^2(0,T;L^2(\Omega))$. We want to conclude that $\zeta_n$ has a (strong) limit point $\zeta \in \mathcal{F}(z)$.

First, by Assumption 1.1 the function $k(\cdot)$ considered as Nemytskii operator, has the property that $k(z_n) \to k(z) \in L^2(0,T;L^2(\Omega))$. Now, since $\zeta_n \in \mathcal{F}(z_n)$, for the unique $p_n = [c_0 I + B]^{-1} \zeta_n$ we
have by definition of $F$ the estimate (4.17) and that the weak form of the equation is satisfied (as in Definition 4). The estimate (4.17) (with fixed RHS in terms of data) yields a uniform-in-$n$ bound on

$$\|p_n\|_{L^2(0,T;V)}, \|p_n\|_{L^\infty(0,T;L^2(\Omega))}, \|B^{1/2}p_n\|_{L^\infty(0,T;L^2(\Omega))}.$$ 

From the bound on $p_n$ in $L^2(0,T;V)$ we extract a weak subsequential limit point, i.e., $p_{n_k} \rightharpoonup p \in L^2(0,T;V)$. From this and the continuity of $[c_0I+B] \in \mathcal{L}(L^2(0,T;L^2(\Omega)))$, we obtain immediately that $\zeta_{n_k} = [c_0I+B]p_{n_k} \rightharpoonup [c_0I+B]p$. We define this latter quantity as $\zeta \equiv [c_0I+B]p$, and hence $\zeta_{n_k} \rightharpoonup \zeta$. In addition, the estimate (4.19) in the definition of $F$ and the uniqueness of limits ensure that (perhaps passing to a further subsequence with the same label) $\zeta_{n_k} \rightharpoonup \zeta \in H^1(0,T;V')$. We want to show that $\zeta \in \mathcal{F}(z)$, and this is accomplished by passing with the limit on the subsequence $n_k$ in the weak formulation (4.3). To that end, let us again consider the weak form evaluated on $n_k$, and restrict our spatial test functions to $q \in L^2(0,T;V) \cap L^\infty(0,T;W^{1,\infty}(\Omega))$:

$$\int_0^T \langle \zeta_{n_k}(t), q(t) \rangle \, dt + \int_0^T A[p_{n_k}(t), q(t); z_{n_k}(t)] \, dt = \int_0^T \langle S(t), q(t) \rangle \, dt \quad (5.4)$$

Limit passage on the first term on the LHS is immediate identifying weak limits in this weak form. For the second term, more care must be taken. Consider:

$$\int_0^T (k(z_{n_k})\nabla p_{n_k}, \nabla q(t)) \, dt = \int_0^T ([k(z_{n_k}) - k(z)]\nabla p_{n_k}, \nabla q(t)) \, dt + \int_0^T (k(z)\nabla p_{n_k}, \nabla q(t)) \, dt. \quad (5.5)$$

The first term on the RHS is handled through the Nemytskii property of $k(\cdot)$:

$$\int_0^T ([k(z_{n_k}) - k(z)]\nabla p_{n_k}, q(t)) \, dt \leq C(\|q\|_{L^\infty(0,T;W^{1,\infty}(\Omega))}) \|k(z_{n_k}) - k(z)\|_{L^2(0,T;L^2(\Omega))} \|p_{n_k}\|_{L^2(0,T;V)} \leq C(q, \|p\|_{L^2(0,T;V)}) |k(z_{n_k}) - k(z)|_{L^2(0,T;L^2(\Omega))} \to 0,$$

by the uniform bound on $p_{n_k}$ in $L^2(0,T;V)$. Convergence of the second term in (5.5) is immediate, since by the boundedness of $k$ we have $k(z)\nabla q \in L^2(0,T;L^2(\Omega))$; thence, $\nabla p_{n_k} \rightharpoonup \nabla p \in L^2(0,T;L^2(\Omega))$.

Thus, we have shown that for $q \in L^2(0,T;V) \cap L^\infty(0,T;W^{1,\infty}(\Omega))$

$$\int_0^T (k(z_{n_k})\nabla p_{n_k}, \nabla q(t)) \, dt \to \int_0^T (k(z)\nabla p, \nabla q(t)) \, dt,$$

and hence, passing to the limit as $k \to \infty$ in (5.4) we obtain for $\zeta = \zeta(z)$ the identity

$$\int_0^T \langle \zeta, q \rangle \, dt + \int_0^T (k(z)\nabla p, \nabla q(t)) \, dt = \int_0^T \langle S(t), q(t) \rangle \, dt \quad (5.6)$$

for all $q \in L^2(0,T;V) \cap L^\infty(0,T;W^{1,\infty}(\Omega))$, the latter being dense in $L^2(0,T;V)$. Thus we have shown that $(\zeta(z), p(z))$ satisfies the weak form of the pressure equation and hence we have constructed a weak solution $(\zeta(z), p(z))$ for $z \in L^2(0,T;L^2(\Omega))$. The requisite estimates in the definition of $\mathcal{F}$ (2.10–2.12) hold immediately on the weak subsequential limit points $(\zeta(z), p(z))$ (in the relevant topologies) by weak lower semicontinuity of norms. Obtaining the initial condition is also immediate from the definition of $\mathcal{F}$. Hence $\zeta_n$ has a weak subsequential limit point $\zeta \in \mathcal{F}(z)$.

To conclude the UHC property of the correspondence $\mathcal{F}$, we must improve the convergence of $\zeta_{n_k} \rightharpoonup \zeta$ strongly in $L^2(\Omega)$. This is done via the Lions-Aubin compactness theorem (see, for
instance, \([19]\)). In addition to the estimate \((4.17)\) for the sequence \(p_{nk}\), we obtain two additional uniform-in-\(k\) estimates from continuity of \(B : V \rightarrow H^1(\Omega)\) and from satisfying the weak form of the pressure equation, namely:

\[
\begin{align*}
\|\mathbf{c}_k p_{nk} + B p_{nk}\|_{L^2(0,T;H^1(\Omega))}^2 &\leq \|p\|_{L^2(0,T;V)}^2, \\
\|\mathbf{c}_k p_{nk}\|_{L^2(0,T;V')}^2 &\leq \|p\|_{L^2(0,T;V)}^2 + \|S\|_{L^2(0,T;V')}^2.
\end{align*}
\]  

(5.7)  

(5.8)

By possibly passing to a further subsequence \(n_{km}\) (not affecting the previous steps in establishing the weak solution or associated estimates), we improve the convergence of \(\zeta_{nk} \rightarrow \zeta \in L^2(0,T;L^2(\Omega))\). Applying Theorem \((5.3)\) we obtain that \(F : L^2(0,T;L^2(\Omega)) \rightarrow L^2(0,T;L^2(\Omega))\) is UHC as well as compact-valued. Subsequently, from Theorem \((7.2)\) we have that \(F\) is a closed correspondence.

**Step III.** Lastly, to invoke the Bohnenblust-Karlin Fixed Point Theorem, we must show that the range of \(F\) is relatively compact in \(L^2(0,T;L^2(\Omega))\). But, as in the previous step, this will follow from the Lions-Aubin compactness criterion. Indeed, for any \(\zeta \in \mathcal{R}(F)\), \(\zeta\) corresponds to a weak solution satisfying the estimate \((4.17)\), and subsequently \((4.18)\)–\((4.19)\). In particular, we obtain for any such \(\zeta\) there is an associated \(p = [\mathbf{c}_0 I + B]^{-1}\zeta\) such that:

\[
\begin{align*}
\|\zeta\|_{L^2(0,T;H^1(\Omega))} &\leq C\|p\|_{L^2(0,T;V)} \leq C\left[\|d_0\|_{L^2(\Omega)}^2 + \|S\|_{L^2(0,T;V')}^2\right], \\
\|\zeta\|_{L^2(0,T;V')} &\leq C\left[\|p\|_{L^2(0,T;V)} + \|S\|_{L^2(0,T;V')}\right] \leq C\left[\|d_0\|_{L^2(\Omega)}^2 + \|S\|_{L^2(0,T;V')}^2\right].
\end{align*}
\]

(5.9)  

(5.10)

A subset of \(L^2(0,T;L^2(\Omega))\) which is bounded as in the previous two estimates is relatively compact by the Lions-Aubin criterion, and hence \(\zeta \in \mathcal{R}(F)\) lies in a compact set. This is the final hypothesis to be satisfied for applying the fixed point result, Theorem \((7.4)\).

Applying the fixed point theorem yields the existence of a function \(z \in L^2(0,T;H^1(\Omega)) \cap H^1(0,T;V')\) and an associated weak solution \((\zeta(z), p(z))\) for which \(z \in \mathcal{R}(z)\). \(\Box\)

**Remark 5.1.** We again note that, owing the presence of the nonlinearity, regularity of the solution \(\zeta\)—in particular of \(\nabla \cdot \mathbf{u}\)—needs to be better than \(L^2(0,T;L^2(\Omega))\). This is because we must obtain compactness in \(\zeta\) to utilize the Nemitskii property of \(k(\cdot)\). Moreover, if \(d_0 \in V'\) only, this would preclude our ability to obtain such regularity, as this would seem to lower the evolution of \(Bp = \nabla \cdot \mathbf{u}\) to the regularity of \(V'\).

Now we proceed to obtain a weak solution as in Definition \(\mathbf{II}\) to the original problem, which is stated in strong form in Section \((3.4)\) as \((3.11)\). By applying the fixed point result from the previous section, Theorem \((5.1)\) with appropriately scaled/modified data \(S, d_0, k(\cdot)\) we will finally prove the main result Theorem \((2.2)\).

**Proof of Theorem \((2.2)\)** Considering the strong form of the nonlinear dynamics in \((3.11)\), we apply the translation as in Section \((3.4)\). For the new variable \(\mathbf{w} = \mathbf{u} - \mathbf{u}_F\), where \(\mathbf{u}_F\) is defined by \((3.8)\), we obtain the system \((3.12)\), which we restate here for clarity:

\[
\begin{align*}
\mathcal{E}(\mathbf{w}) &= -\nabla p, &\quad \mathbf{w} &\in L^2(0,T;V') \\
[\mathbf{c}_0 p + \nabla \cdot \mathbf{w}]_t - \nabla \cdot [k_F (\mathbf{c}_0 p + \nabla \cdot \mathbf{w})] &= S + \nabla \cdot \mathbf{u}_F t, &\quad \mathbf{w} &\in L^2(0,T;V') \\
\mathbf{c}_0 p(0) + \nabla \cdot \mathbf{w}(0) &= d_0 - \nabla \cdot \mathbf{u}_F(0), &\quad \mathbf{w} &\in L^2(\Omega).
\end{align*}
\]

(5.11)

Under the regularity assumptions on \(F\), we have \(\mathbf{u}_F \in L^2(0,T;H^2(\Omega) \cap V) \cap H^1(0,T;V)\). Hence, in the above strong form, we have \(\nabla \cdot \mathbf{u}_F t \in L^2(0,T;H^2(\Omega)) \subset L^2(0,T;V')\). Additionally, \(\nabla \cdot \)
\( \mathbf{u}_B \in C([0,T];L^2(\Omega)) \) \[13\] [19], so we can extract its time trace at \( t = 0 \). Finally, since \( \nabla \cdot \mathbf{u}_B \in C([0,T];L^2(\Omega)) \), we observe \( k_B(\cdot) = k(\cdot + \nabla \cdot \mathbf{u}_B) \) satisfies the hypotheses of Assumption \[11\] since \( k(\cdot) \) is assumed to satisfy them. We can then reduce the above system to a version of \[5.1\], where the corresponding “data” satisfies the hypotheses of Theorem \[5.1\] and we can apply the result of the fixed point theorem.

Doing so, we obtain a function \( p \in L^2(0,T;V) \) that satisfies:

- For every \( q \in L^2(0,T;V) \),
  \[ \int_0^T \langle [(c_0I + B)p]'(t), q \rangle dt + \int_0^T (c_0p + Bp + \nabla \cdot \mathbf{u}_B) \nabla \cdot q dt = \int_0^T (S, q) dt + \int_0^T (\nabla \cdot \mathbf{u}_B, q) dt. \]
- \( \zeta = c_0p + Bp \) a.e. \( t \) and a.e. \( x \).
- \( [(c_0I + B)p](0) = d_0 \) in the sense of \( V' \).

The following estimates hold:

\[
\begin{align*}
c_0 ||p||_{L^2(\Omega)}^2 + ||B^{1/2}p(t)||_{L^2(\Omega)}^2 + ||p||_{L^2(0,T;V)} & \lesssim ||d_0||_{L^2(\Omega)}^2 + ||\nabla \cdot \mathbf{u}_B||_{L^2(\Omega)}^2 + ||S||_{L^2(0,T;\mathcal{V}')}^2 \\
||[(c_0I + B)p]'||_{L^2(0,T;\mathcal{V}')} & \lesssim ||p||_{L^2(0,T;V)} + ||S||_{L^2(0,T;\mathcal{V}')} + ||\nabla \cdot \mathbf{u}_B||_{L^2(0,T;\mathcal{V}')} \\
||[c_0p + \nabla \cdot \mathbf{u}']||_{L^2(0,T;\mathcal{V}')} & \lesssim ||p||_{L^2(0,T;V)} + DAT_A||_{0}^{T} \\
||c_0p + \nabla \cdot \mathbf{u}||_{L^2(0,T;H^1(\Omega))} & \lesssim ||p||_{L^2(0,T;V)}. \end{align*}
\]

From this we can obtain a \( w \in L^2(0,T;H^2(\Omega) \cap \mathcal{V}) \) and then a \( \mathbf{u} = w + \mathbf{u}_B \), resulting in
\[
\nabla \cdot \mathbf{u} = Bp + \nabla \cdot \mathbf{u}_B
\]
in a point-wise sense. The above is sufficient to conclude the weak form of the elasticity equation, \[2.6\]. Using the fact that \( ||\mathbf{u}_B||_{\mathcal{V}} \lesssim ||\mathbf{F}||_{\mathcal{V}} \) and the embedding \( H^1(0,T;L^2(\Omega)) \hookrightarrow C([0,T];L^2(\Omega)) \), we re-interpret the estimates above as

\[
\begin{align*}
c_0 ||p||_{L^2(0,T;L^2(\Omega))}^2 + ||p||_{L^2(0,T;V)} & \lesssim ||d_0||_{L^2(\Omega)}^2 + DAT_A||_{0}^{T} \\
||\mathbf{u}||_{L^2(0,T;H^2(\Omega) \cap \mathcal{V})} & \lesssim ||p||_{L^2(0,T;V)} + ||\mathbf{F}||_{L^2(0,T;L^2(\Omega))}^2 \\
||[c_0p + \nabla \cdot \mathbf{u}']||_{L^2(0,T;\mathcal{V}')} & \lesssim ||p||_{L^2(0,T;V)} + DAT_A||_{0}^{T} \\
||c_0p + \nabla \cdot \mathbf{u}||_{L^2(0,T;H^1(\Omega))} & \lesssim ||p||_{L^2(0,T;V)}. \end{align*}
\]

(Note that in these final estimates for the original problem we have omitted references to the \( B \) operator, in doing so, discarding the information on \( B^{1/2}p \in L^\infty(0,T;L^2(\Omega)) \).)

This finally concludes the proof of Theorem \[2.2\] \( \square \)

5.2 Proof of Theorem \[2.2\] - Incompressible Constituents, \( c_0 = 0 \)

Consider a sequence or real numbers \( \{c_0^m\}_1^\infty \) such that \( c_0^m < 1 \), for all \( m \geq 1 \), and \( c_0^m \downarrow 0 \) as \( m \to \infty \). To each \( c_0^m \) we attribute a particular weak solution \( (p^m, \mathbf{u}^m) \in L^2(0,T;V) \times L^2(0,T;\mathcal{V}) \) to \[4.11\] (i.e., a solution in the sense of Definition \[14\] with a fixed initial condition \( d_0 \in L^2(\Omega) \) for
all $m$ (the intended initial condition when $c_0 = 0$). Such a solution has, by construction in the proof of Theorem 2.2, the energy estimate:

$$c_0^m ||p^m||^2_{L^2((0,T);L^2(\Omega))} + k_1 \int_0^T ||\nabla p^m||^2 dt \lesssim ||d_0||^2 + DAT_{A_0}^{T}.$$  

Note, the bound on the RHS is uniform in $m$. This provides a weak-* subsequential limit point for $\sqrt{c_0^m}p^m \in L^\infty(0,T; L^2(\Omega))$, and a weak subsequential limit point labeled $p$ for the sequence $p^m \in L^2(0,T; V)$. From the elasticity equation, we infer that the associated $u^m \in L^2(0,T; H^2(\Omega) \cap V)$ has the bound

$$\int_0^T ||u^m||^2_{H^2(\Omega) \cap V} dt \lesssim \int_0^T ||E(u^m)||^2 dt \lesssim \int_0^T ||\nabla p^m||^2 dt + \int_0^T ||F||^2_{L^2(\Omega)} dt,$$

and taken in conjunction with the estimate above, leads to a uniform-in-$m$ estimate. To the sequence $u^m$ we also associate a weak subsequential limit point (with the same subsequence associated to $p$, perhaps upon re-indexing):

$$u^m \rightharpoonup u \in L^2(0,T; V).$$

From the construction of the weak solution, we have that $p^m$ satisfies for all $q \in L^2(0,T; V)$:

$$\int_0^T \langle \zeta^m_t(t), q(t) \rangle dt + \int_0^T (k(\zeta^m(t))\nabla p^m(t), \nabla q(t)) dt = \int_0^T \langle S(t), q(t) \rangle dt,$$

with $\zeta^m = c_0^m p^m + \nabla \cdot u^m = [c_0^m I + B]p^m + \nabla \cdot u_F \in L^2(0,T; L^2(\Omega))$ and the associated bound

$$||\zeta^m||_{L^2(0,T;L^2(\Omega))} = ||c_0^m p^m + \nabla \cdot u^m||_{L^2(0,T; L^2(\Omega))} \leq c_0^m ||p^m||_{L^2(0,T; L^2(\Omega))} + ||\nabla \cdot u^m||_{L^2(0,T; L^2(\Omega))} \leq C||p||_{L^2(0,T; V)} + ||u||_{L^2(0,T; V)} \lesssim ||d_0||^2 + DAT_{A_0}^{T} + ||F||^2_{L^2(0,T; L^2(\Omega))}$$

by lower weak semicontinuity of the norm, Poincaré, and the boundedness of the sequence $\{c_0^m\}$. Hence there is $\zeta \in L^2(0,T; L^2(\Omega))$ so that

$$\zeta^m \rightharpoonup \zeta \in L^2(0,T; L^2(\Omega)).$$

As in the construction of the solution, satisfying the equation \([5.16]\) is also sufficient to deduce that $\zeta^m \in L^2(0,T; V')$ (with associated uniform-in-$m$ bound as above in \([5.14]\)). Again, by such a uniform-in-$m$ bound on $\zeta^m \in L^2(0,T; V')$ we can extract a weak subsequential limit in that space, and identify in the standard way for the distributional derivative \([14]\)

$$\zeta^m_t \rightharpoonup \zeta_t \in L^2(0,T; V').$$

Additionally, the sequence $p^m$ itself is bounded as

$$||p^m||_{L^2(0,T; L^2(\Omega))} \leq C||p^m||_{L^2(0,T; V)} \lesssim ||p||_{L^2(0,T; V)}.$$

This implies that the sequence $[c^m p^m] \to 0 \in L^2(0,T; L^2(\Omega))$, as well as, for any $\phi \in V$ and $f \in D(0,T)$,

$$c_0^m \int_0^T (p^m(t), \phi)_\Omega f'(t) dt \to 0,$$
of course yields the weak form in Definition (4).

\[ \int_0^T \langle p^m(t), q(t) \rangle_{V' \times V} \, dt \to 0, \quad \forall q \in L^2(0, T; V). \]  

(5.19)

Now, it is immediate from the previously established convergences that \( \zeta^m = c_0^m p^m + \nabla \cdot u^m \to \nabla \cdot u \in L^2(0, T; L^2(\Omega)) \), and by uniqueness of limits, we must have that \( \zeta = \nabla \cdot u \in L^2(0, T; L^2(\Omega)) \), possibly passing to a subsequence. Moreover, since \( \zeta^m \in L^2(0, T, V') \) with \( c_0^m p^m \to 0 \), we obtain that

\[ \int_0^T \langle \zeta^m, q \rangle \, dt \to \int_0^T \langle \zeta, q \rangle, \quad \int_0^T \langle \zeta^m, q \rangle \, dt = \int_0^T [\langle c_0^m p^m, q \rangle + \langle \nabla \cdot u^m, q \rangle] \, dt. \]

But we know, again by uniqueness of limits, since we have (5.19), that

\[ \int_0^T \langle \zeta^m, q \rangle \, dt \to \int_0^T \langle \zeta, q \rangle \, dt = \int_0^T \langle \nabla \cdot u, q \rangle \, dt. \]

Lastly, we need to show the nonlinear term exhibits convergence; namely, we want to show

\[ \int_0^T (k(\zeta^m) \nabla p^m, \nabla q) \, dt \to \int_0^T (k(\nabla \cdot u) \nabla p, \nabla q) \, dt. \]  

(5.20)

This will follow immediately as in Step II in the proof of Theorem 5.1, using the Nemytskii property of \( k(\cdot) \). Indeed, we first improve the bounds on \( \zeta^m \):

\[ \| \zeta^m \|_{L^2(0, T; H^1(\Omega))} = \| c_0^m p^m + \nabla \cdot u^m \|_{L^2(0, T; H^1(\Omega))} \]

\[ \lesssim c_0^m \| p^m \|_{L^2(0, T; V)} + \| u^m \|_{H^2(\Omega)}^2 \]

\[ \lesssim \| p \|_{L^2(0, T; V)} + \| u \|_{L^2(0, T; V \cap H^2(\Omega))}. \]  

(5.21)

This again results in uniform-in-m boundedness, and we note that (perhaps on a subsequence), again by The Lions-Aubin criterion and the uniform boundedness of \( \{ \zeta^m \} \subset L^2(0, T; H^1(\Omega)) \) and \( \{ \zeta^m \} \subset L^2(0, T; V') \), we can improve the convergence of \( \zeta^m \to \zeta \in L^2(0, T; L^2(\Omega)) \) to strong convergence. At this point, \( k(\zeta^m) \to k(\zeta) \in L^2(0, T; L^2(\Omega)) \), and we invoke the identification \( \zeta = \nabla \cdot u \). From this, (5.20) follows.

Hence, upon taking the limit as \( c_0^m \to 0 \) in (5.16), we obtain that the subsequential limit point \((p, u) \in L^2(0, T; V \times V)\) satisfies:

\[ \int_0^T \langle \nabla \cdot u(t), q \rangle \, dt + \int_0^T (k(\zeta(t)) \nabla p(t), \nabla q) \, dt = \int_0^T \langle S(t), q \rangle f(t) \, dt, \]  

(5.22)

for any \( q \in L^2(0, T; V) \).

As in the \( c_0 > 0 \) case, we recover the elasticity equation faithfully, so

\[ \mathcal{E}(u) = -\nabla p + F, \quad \text{a.e. } x, t, \]

which of course yields the weak form in Definition (4).

Finally, by the equation, we again have that \( \nabla \cdot u \in H^1(0, T; V') \cap L^2(0, T; H^1(\Omega)) \), so \( \nabla \cdot u \in C([0, T]; V') \), which permits the initial condition for the quantity \( \nabla \cdot u(0) = d_0 \) in the \( V' \) sense, though \( d_0 \in L^2(\Omega) \). This ensures that \((p, u) \in L^2(0, T; V \times V)\) is in fact a weak solution with \( c_0 = 0 \), in the sense of Definition (4) (see Remark 2.1).
6 Uniqueness - Proof of Theorem 2.3

In this section we divide our considerations into two approaches, depending on which terms have point-wise-in-\(t\) control: (i) the first one considers a weak solution to the full dynamical system in both dependent variables \((u, p)\); (ii) the second approach considers the reduced system phrased in terms of \(p\) and \(Bp\). There are subtle differences in the approaches and in the requisite hypotheses to obtain unique solutions. We point out that—since we do not construct strong solutions in this paper—we phrase our results below as: If weak solutions exhibit additional regularity properties, then among such weak solutions there is uniqueness. We recall the space of weak solutions (for given data \(d_0, S, F, k(\cdot)\)) with the additional regularity \(p_t \in L^2(0,T;L^2(\Omega))\) denoted by \(\mathcal{W}_T\)—see \ref{2.13}. In particular, our result says: If one weak solution in \(\mathcal{W}_T\) has additional spatial regularity, then all weak solutions in \(\mathcal{W}_T\) are equal to it.

Let us introduce both types of formal energy identities utilized later in the proof of Theorem \ref{2.3} for \(c_0 \geq 0\). Consider \((u^1, p^1)\) and \((u^2, p^2)\) two weak solutions coming from \(\mathcal{W}_T\). Then, we subtract the weak forms of the equations as in Definition \ref{1} and test the pressure equation with \(\overline{p} = p^1 - p^2\) and the elasticity equation with \(\overline{u}_t = u^1_t - u^2_t\). The latter is justified, as \(u^i_t = \mathcal{E}^{-1}(\nabla p^i + F_t) \in L^2(0,T;V)\) since \(F_t \in L^2(0,T;V')\) by our regularity hypotheses on \(F\) and \(\nabla p^i \in L^2(0,T;V')\) since \(p^i_t \in L^2(0,T;L^2(\Omega))\).

This yields the unsimplified identities:
\[
\int_0^T \langle \mathcal{E}(\overline{u}), \overline{u}_t \rangle_{V \times V'} dt - \int_0^T \langle \overline{p}, \nabla \cdot \overline{u} \rangle_{\Omega} dt = 0 \tag{6.1}
\]
\[
\int_0^T [c_0(\overline{p}_t, \overline{p})_\Omega + (\nabla \cdot \overline{u}_t, \overline{p})_\Omega] dt + \int_0^T (k(\zeta^1)\nabla p^1 - k(\zeta^2)\nabla p^2, \nabla \overline{p})_\Omega dt = 0, \tag{6.2}
\]
where we denote \(\zeta^i = c_0 p^i + \nabla \cdot u^i\).

Now, let us consider the formal energy relation for the (partial, omitting the equation for \(u\)) reduced formulation making use of the \(B\) operator, again, with no simplifications:
\[
([c_0 I + B]\overline{p}_t, \overline{p})_\Omega + (k(\zeta^1)\nabla p^1 - k(\zeta^2)\nabla p^2, \nabla \overline{p})_\Omega = 0. \tag{6.3}
\]

We have replaced the \(V' \times V\) duality pairings in the pressure equations above through the assumption that \(p^i_t \in L^2(0,T;L^2(\Omega))\). Both approaches to uniqueness hinge on the analysis of the nonlinear term. The goal is to apply a version of Grönwall to the formal estimates.

Let us begin by estimating directly this nonlinear term above.
\[
\int_0^T ([k^1(t)\nabla p^1(t) - k^2(t)\nabla p^2(t)], \nabla \overline{p}) dt = \int_0^T ([k^1(t) - k^2(t)]\nabla p^1(t), \nabla \overline{p}(t)) dt \tag{6.4}
\]
\[
+ \int_0^T (k^2(t)\nabla \overline{p}(t), \nabla \overline{p}(t)) dt,
\]
where we have used the shorthand \(k^i(t) \equiv k(c_0 p^i + \nabla \cdot u^i)\). Using the lower bound on the permeability function \(0 < k_1 \leq k(\cdot)\) from Assumption \ref{1} the second term above will serve as dissipation to help with further estimation
\[
k_1 ||\overline{p}||_{L^2(0,T;V)}^2 \leq \int_0^T (k^2(t)\nabla \overline{p}(t), \nabla \overline{p}(t)) dt.
\]

The remaining nonlinear term on the RHS can be estimated in two ways, yielding the two distinct hypotheses. With the supplemental hypothesis that \(k \in Lip(\mathbb{R})\) with \(L_k > 0\) the global
Lipschitz constant, we have

\[ |k^1(t) - k^2(t)| = |k(\xi^1) - k(\xi^2)| \leq L_k|\xi|, \]

again where \( \xi = \xi^1 - \xi^2 \), and \( \xi^i = c_0p^i + \nabla \cdot u^i \).

Using Cauchy-Schwartz, then, we have

\[ \int_0^T ([k^1(t) - k^2(t)]\nabla p(t), \nabla \overline{p}(t)) dt \leq L_k \int_0^T \|\nabla p(t)\|_{L^\infty(\Omega)} \|\xi\|_{L^2(\Omega)} \|\nabla \overline{p}\|_{L^2(\Omega)} dt. \]

We proceed straightforwardly, retaining the supremum term under the integration:

\[ \int_0^T ([k^1(t) - k^2(t)]\nabla p(t), \nabla \overline{p}(t)) dt \leq \int_0^T \left[ L_k \|\nabla p(t)\|_{L^\infty(\Omega)} \|\xi(t)\|_{L^2(\Omega)} \|\nabla \overline{p}\|_{L^2(\Omega)} dt \right] \]

\[ \leq \int_0^T \frac{L^2_k}{4\epsilon} \|\nabla \overline{p}(t)\|^2_{L^2(\Omega)} \|\xi(t)\|^2_{L^2(\Omega)} dt \quad \text{(6.5)} \]

\[ + \epsilon \int_0^T \|\nabla \overline{p}\|^2_{L^2(\Omega)} dt, \quad \forall \epsilon > 0. \]

**Remark 6.1.** One can also pull the supremum term outside the integral; this is akin to the approach taken in [3].

\[ \int_0^T ([k^1(t) - k^2(t)]\nabla p(t), \nabla \overline{p}(t)) dt \leq \frac{L^2_k}{4\epsilon} \|\nabla p(t)\|^2_{L^\infty(0,T; L^\infty(\Omega))} \int_0^T \|\xi(t)\|^2_{L^2(\Omega)} dt \]

\[ + \epsilon \int_0^T \|\nabla \overline{p}\|^2_{L^2(\Omega)} dt, \quad \forall \epsilon > 0. \]

Anticipating the use of Grönwall below, we note that \( \nabla p^1 \in L^\infty(\Omega) \) is obtained through the Sobolev embeddings in 3-D if for instance, if \( p^1 \in H^3(\Omega) \) (or any Sobolev index above 2.5).

### 6.1 Uniqueness for the Full System; \( c_0 \geq 0 \)

In working with the full system, we can exploit cancellation in the structure of the Biot system to obtain more explicit energy estimates to be used for uniqueness. In this framework, as we shall see, we need to specify the initial displacement \( u_0 \in V \) independently of \( c_0p_0 \), recalling that \( \xi(0) = d_0 = [c_0p + \nabla \cdot u](0) \).

Then, we consider (6.1)–(6.2) and add the two equations, cancelling cross-terms on the RHS and simplifying by integration by parts. This yields:

\[ a(\overline{u}(t), \overline{u}(t)) + c_0\|\overline{p}(t)\|^2 + 2 \int_0^t (k(\xi^1)\nabla p(t) - k(\xi^2)\nabla p(t), \nabla \overline{p}(t)) dt = a(\overline{u}_0, \overline{u}_0) + c_0\|\overline{p}_0\|^2. \quad \text{(6.6)} \]

We recall the estimate on a single trajectory:

\[ \|u\|^2_{L^\infty(0,T; V)} + c_0\|p\|^2_{L^\infty(0,T; L^2(\Omega))} + k_1\|p\|^2_{L^2(0,T; V)} \leq C(u_0, p_0) + DAT A |^T_0. \quad \text{(6.7)} \]

The resulting estimate on \( (\overline{u}, \overline{p}) \) as above in (6.5) is

\[ \|\overline{u}\|^2_{L^\infty(0,T; V)} + c_0\|\overline{p}\|^2_{L^\infty(0,T; L^2(\Omega))} + k_1\|\overline{p}\|^2_{L^2(0,T; V)} \leq C(\overline{u}_0, \overline{p}_0) + \int_0^T (\nabla p(t), \nabla \overline{p}(t)) dt, \]

\[ \leq \frac{L^2_k}{4\epsilon} \int_0^T \|\nabla \overline{p}(t)\|^2_{L^2(\Omega)} \|\xi(t)\|^2_{L^2(\Omega)} dt \]

\[ + \epsilon \int_0^T \|\nabla \overline{p}\|^2_{L^2(\Omega)} dt \quad \text{(6.8)} \]

27
We then note that $$\zeta = c_0 \overline{p} + \nabla \cdot \overline{\mathbf{u}}$$, and hence

$$||\zeta||^2 \lesssim c_0^2 ||\overline{p}||^2 + ||\overline{\mathbf{u}}||_V^2.$$  

Absorbing on the RHS by choosing, e.g., $$\epsilon = \frac{k_2}{k_1},$$ we obtain:

$$||\overline{\mathbf{u}}||_{L^\infty(0,T;V)}^2 + c_0||\overline{p}||_{L^\infty(0,T;L^2(\Omega))}^2 \lesssim \frac{L_2^2}{k_1} \int_0^T ||\nabla \overline{p}(t)||_{L^\infty(\Omega)}^2 \left[c_0^2||\overline{p}||^2 + ||\overline{\mathbf{u}}||_V^2\right] dt. \quad (6.9)$$

If $$c_0 < 1$$, then we have

$$||\overline{\mathbf{u}}||_{L^\infty(0,T;V)}^2 + c_0||\overline{p}||_{L^\infty(0,T;L^2(\Omega))}^2 \leq \frac{L_2^2}{k_1} \int_0^T ||\nabla \overline{p}(t)||_{L^\infty(\Omega)}^2 \left[c_0||\overline{p}||^2 + ||\overline{\mathbf{u}}||_V^2\right] dt \quad (6.10)$$

If $$c_0 > 1$$, then we have

$$||\overline{\mathbf{u}}||_{L^\infty(0,T;V)}^2 + c_0||\overline{p}||_{L^\infty(0,T;L^2(\Omega))}^2 \leq \frac{L_2^2 c_0}{2k_1} \int_0^T ||\nabla \overline{p}(t)||_{L^\infty(\Omega)}^2 \left[c_0||\overline{p}||^2 + ||\overline{\mathbf{u}}||_V^2\right] dt \quad (6.11)$$

From here, we may invoke $$L^2$$-kernel version of Grönwall as in [12, Theorem 9], and uniqueness of solutions is deduced in the standard way.

**Remark 6.2 (Weakening hypotheses).** Recalling the space $$H_2 = \nabla H_0^1(\Omega) = \nabla V$$ (from [22]), we note that for weak solutions we have that $$\mathbf{u}_t \in L^2(0,T;[H_2]'),$$ by satisfying the weak form of the pressure equation (since it can act on $$\nabla q \in \nabla V$$). On the other hand, since $$\mathbf{p} \in L^2(0,T;V),$$ we have that $$\nabla \mathbf{p} \in L^2(0,T;H_2).$$ Thus, the “cross-terms” $$\langle \nabla \cdot \mathbf{u}_t, \mathbf{p} \rangle$$ and $$\langle \nabla \mathbf{p}, \mathbf{u}_t \rangle$$ can both be interpreted in the $$[H_2]' \times H_2$$ sense. In addition, through satisfying the elasticity equation, we have that $$\mathbf{E}(\mathbf{u}) = \nabla \mathbf{p} \in H_2,$$ and hence the pairing $$\langle \mathbf{E}(\mathbf{u}), \mathbf{u}_t \rangle$$ is also defined similarly. Hence, we could reduce our uniqueness assumption on the solutions to: for a weak solution $$(\mathbf{u}, \mathbf{p})$$, the $$[H_2]' \times H_2$$ duality pairing below has the property that

$$\langle \mathbf{E}(\mathbf{u}), \mathbf{u}_t \rangle_{H_2 \times [H_2]'} = \frac{1}{2} \frac{d}{dt} \tilde{a}(\mathbf{u}, \mathbf{u}),$$

which may not be the case in general.

### 6.2 Reduced Equation Uniqueness; $$c_0 > 0$$

In this section we consider working with the reduced equation directly. We assume only that $$d_0 \in L^2(\Omega),$$ forgoing any assumptions on $$\mathbf{u}(t = 0).$$ As we will see, we need to assume $$c_0 > 0$$ as well.

So, given $$\mathbf{F}$$ and $$S$$ as above, let us consider two weak solutions $$\mathbf{p}_i(t) \in L^2(0,T;V) \cap H^1(0,T;L^2(\Omega))$$ (this follows, for instance, if $$(\mathbf{u}, \mathbf{p}) \in W_T$$ and the problem is reduced through the $$B$$ operator) to

$$[c_0 I + B] \mathbf{p}_i - \nabla \cdot k(\zeta) \nabla \mathbf{p}_i = S + \nabla \cdot \mathbf{u}_{\mathbf{F},t} \in L^2(0,T;V'),$$

using the notation from Section 3.4. We will denote $$\zeta = c_0 \mathbf{p} + B \mathbf{p} + \nabla \cdot \mathbf{u}_F$$ here for the fluid content.

**Remark 6.3 (Weakening hypotheses).** Here, the main regularity we need is to be able to interpret the pairing $$\langle [c_0 I + B] \mathbf{p}_i, \mathbf{p} \rangle$$ in some sense. The challenge is that the properties of $$B$$ in both $$V$$ and $$V'$$ are not clear (e.g., self-adjointness), and for $$\mathbf{p} \in L^2(0,T;V),$$ it is not clear that $$B \mathbf{p} \in L^2(0,T;V).$$
Let $\overline{p} = p^1 - p^2$ as before, and hence $\zeta = c_0 \overline{p} + B \overline{p}$. Then the straightforward energy relation in (6.3) simplifies to

$$\frac{1}{2} \frac{d}{dt} [c_0 ||p||^2 + (B \overline{p}, p)] + (k(\zeta^1) \nabla p^1 - k(\zeta^2) \nabla p^2, \nabla \overline{p}) = 0.$$ 

Add and subtract, anticipating using the Lipschitz property of $k$:

$$c_0 ||p(t)||^2 + ||B^{1/2} \overline{p}(t)||^2 + 2 \int_0^t (\nabla p_1[k(\zeta^1) - k(\zeta^2)], \nabla \overline{p}) + (k(\zeta^2) \nabla p, \nabla \overline{p}) dt = (d_0, \overline{p}(0)).$$ 

Since $c_0 > 0$, we can recover $p(0) = p_0 = [c_0 I + B]^{-1} d_0$. Estimating as in the previous section and invoking the assumptions on $k(\cdot)$, we obtain

$$c_0 ||\overline{p}||_{L^\infty(0, T; L^2(\Omega))}^2 + ||B^{1/2} \overline{p}||_{L^\infty(0, T; L^2(\Omega))}^2 + k_1 ||\overline{p}||_{L^2(0, T; V)}^2 \lesssim ||d_0||^2 + \frac{L_k}{k_1} \int_0^T ||\nabla p^1||_{L^\infty(\Omega)} ||\zeta||_{L^2(\Omega)}^2 d\tau.$$ 

To proceed as before with Grönwall, it is imperative here that $c_0 > 0$ since we do not know that $B$ or $B^{1/2}$ is coercive. We then estimate $\zeta$ carefully:

$$||\zeta|| = ||c_0 \overline{p} + B \overline{p}|| \leq C ||p||,$$

where all norms are taken in the $L^2(\Omega)$ sense. Simplifying the above inequality, and invoking this estimate, we obtain

$$c_0 ||\overline{p}||_{L^\infty(0, T; L^2(\Omega))}^2 \lesssim ||d_0||_{L^2(\Omega)}^2 + \frac{L_k}{k_1} \int_0^T ||\nabla p^1||_{L^\infty(\Omega)} ||\overline{p}||_{L^2(\Omega)}^2 d\tau. \tag{6.12}$$

Since $p \in H^1(0, T; L^2(\Omega))$ in this case, $p \in C([0, T]; L^2(\Omega))$ and at this point, Grönwall can be applied as before to obtain uniqueness in $p$ a.e. $t$ and $x$, which can then be transferred through the elasticity isomorphism $E$ to $p$. This results in uniqueness of the weak solution $(u, p) \in W_T$.

## 7 Appendix: Multivalued Fixed Point

We begin with a handful of definitions and straightforward theorems that will be relevant to the fixed point we are using in the construction of weak solutions. All of these considerations are taken from [1].

The basic setting considers $\phi : X \rightarrow Y$ as a correspondence, where, for each $x \in X$, $\phi(x)$ represents a subset of $Y$. (We do not use the equivalent point of view that $\phi : X \rightarrow 2^Y.$) The $\rightarrow$ notation indicates that $\phi$ need not be a function, but is thought of as a “multi-valued function.”

**Definition 6** (Notions of Closedness and Compactness). A correspondence $\phi : X \rightarrow Y$ between topological spaces is **closed-valued** if $\phi(x)$ is a closed set for each $x \in X$. The analogous definition is used for a **compact-valued** correspondence.

A correspondence $\phi : X \rightarrow Y$ between topological spaces is **closed** (or has a closed graph) if

$$\mathcal{G}(\phi) \equiv \{(x, y) \in X \times Y : y \in \phi(x)\}$$

is closed as a subset of $X \times Y$. 

Definition 7. A correspondence \( \phi : X \rightarrow Y \) between topological spaces is called upper hemicontinuous (or UHC) at the point \( x \in X \) if for every neighborhood \( U \ni x \) there is a neighborhood \( V \ni x \) such that
\[
z \in V \implies \phi(z) \subseteq U.
\]
We say that \( \phi \) is UHC on \( X \) if it is UHC at each \( x \in X \).

The next theorem provides the relationship between graph closedness and UHC. (We do not explicitly use this version in the body of the paper.)

**Theorem 7.1.** Suppose \( \phi : X \rightarrow Y \) is closed-valued. If \( \phi \) is UHC at \( x \), then for all \( x_n \in X \), \( y \in Y \), and \( y_n \in \phi(x_n) \)
\[
x_n \rightarrow x \quad \text{and} \quad y_n \rightarrow y \quad \implies \quad y \in \phi(x).
\]
If \( \phi \) is closed-valued and the range of \( \phi \) is compact, then the converse holds.

Alternatively, the following is the criteria we invoke in the proof of our main result:

**Theorem 7.2.** Suppose \( \phi : X \rightarrow Y \) is an UHC correspondence. If \( \phi \) is closed-valued (and \( Y \) is regular) OR \( \phi \) is compact-valued (and \( Y \) is Hausdorff), then \( \phi \) is closed.

The next theorem is a subtle variation on the previous sequential criteria for upper-hemicontinuity.

**Theorem 7.3.** Assume that a topological space \( X \) is first countable and \( Y \) is metrizable. Then for a correspondence \( \phi : X \rightarrow Y \) and a point \( x \in X \) TFAE:

- \( \phi \) is UHC at \( x \) and \( \phi(x) \subset Y \).
- If a sequence \( \{ (x_n, y_n) \} \) in \( \mathcal{G}(\phi) \) satisfies \( x_n \rightarrow x \) then \( \{ y_n \} \) has a limit point in \( \phi(x) \).

Finally, we are in a position to state the multi-valued fixed point theorem employed in our constructions above, the *Bohnenblust-Karlin* theorem. Historically, this theorem has been considered as the multi-valued version of the Schauder fixed point theorem. Let us note that fixed point for a correspondence \( \phi : X \rightarrow X \) is simply a point \( x \in X \) so that \( x \in \phi(x) \).

**Theorem 7.4 (Bohnenblust-Karlin).** Let \( X \) be a nonempty closed convex subset of a locally Hausdorff space, and let \( \varphi : X \rightarrow X \) be a correspondence with closed graph and nonempty convex values. If the range of \( \varphi \) is relatively compact (or equivalently, if it is included in a compact set), then the set of fixed points of \( \varphi \) is nonempty and compact.
