SKREW POLYNOMIAL RINGS, GRÖBNER BASES AND THE LETTERPLACE EMBEDDING OF THE FREE ASSOCIATIVE ALGEBRA

ROBERTO LA SCALA* AND VIKTOR LEVANDOVSKYY**

Abstract. In this paper we introduce an algebra embedding \(\iota : K\langle X\rangle \to S\) from the free associative algebra \(K\langle X\rangle\) generated by a finite or countable set \(X\) into the skew monoid ring \(S = P \ast \Sigma\) defined by the commutative polynomial ring \(P = K[X \times \mathbb{N}^*]\) and by the monoid \(\Sigma = \langle \sigma \rangle\) generated by a suitable endomorphism \(\sigma : P \to P\). If \(P = K[X]\) is any ring of polynomials in a countable set of commuting variables, we present also a general Gröbner bases theory for graded two-sided ideals of the graded algebra \(S = \bigoplus S_i\) with \(S_i = P \sigma^i\) and \(\sigma : P \to P\) an abstract endomorphism satisfying compatibility conditions with ordering and divisibility of the monomials of \(P\). Moreover, using a suitable grading for the algebra \(P\) compatible with the action of \(\Sigma\), we obtain a bijective correspondence, preserving Gröbner bases, between graded \(\Sigma\)-invariant ideals of \(P\) and a class of graded two-sided ideals of \(S\). By means of the embedding \(\iota\) this results in the unification, in the graded case, of the Gröbner bases theories for commutative and non-commutative polynomial rings. Finally, since the ring of ordinary difference polynomials \(P = K[X \times \mathbb{N}]\) fits the proposed theory one obtains that, with respect to a suitable grading, the Gröbner bases of finitely generated graded ordinary difference ideals can be computed also in the operators ring \(S\) and in a finite number of steps up to some fixed degree.

1. Introduction

Let \(P\) be a \(K\)-algebra and let \(\Sigma\) be a monoid of endomorphisms of \(P\). If \(I\) is an ideal of \(P\) which is invariant under the maps in \(\Sigma\) then it is possible to codify the action of \(P\) and \(\Sigma\) over \(I\) as a single left module structure with respect to the skew monoid (or semigroup) ring \(S = P \ast \Sigma\). The study of some properties of \(I\), as for instance its finite \(\Sigma\)-generation, can be reduced hence to that of general properties of the operators ring \(S\) as its Noetherianity (see [26, 21]). Ideals which are stable under the action of monoids of endomorphisms or groups of automorphisms are natural in many contexts as the representation theory (a classical reference is [6]), or in the study of PI-algebras [5, 13] where \(P\) is the free associative algebra and \(\Sigma\) the complete monoid of endomorphisms of \(P\). Another context of relevant interest is the study of so-called “difference ideals” [23] which are ideals invariant under shift operators in applications to combinatorics, (nonlinear) differential and difference equations. For the viewpoint of computing in the ring of (differential-difference) operators an important contribution is [25].

To control in an effective way the structure of the left \(S\)-module \(P/I\) one generally needs to compute a \(K\)-basis of it. If \(P\) is a ring of polynomials in commutative or
non-commutative variables and one fixes a suitable ordering for the monomials of $P$, then a $K$-linear basis of monomials for $P/I$ can be obtained by using the elements of a suitable generating set of $I$ as rewriting rules. Such generating set is usually called a “Gröbner basis” of $I$. Since $I$ is a $\Sigma$-invariant ideal, it is natural to consider $\Sigma$-bases of $I$ that is sets $G \subset I$ such that $I$ is the smallest $\Sigma$-ideal of $P$ containing $G$. In other words, $G$ is a generating set of $I$ as left $\Sigma$-module. It follows that one has to harmonize the notion of Gröbner basis with that of $\Sigma$-basis and attempts in this direction can be found for instance in [1, 3] and also in [9, 22]. If the elements of $\Sigma$ are automorphisms, the main obstacle in the definition of a Gröbner $\Sigma$-basis is that their action on $P$ does not preserve the monomial ordering. Then, it has been shown in [3] and before in [22] that an appropriate setting to define Gröbner $\Sigma$-bases is that of a commutative polynomial ring $P = K[X]$ in an infinite number of variables and a monoid $\Sigma$ of monomial monomorphisms of infinite order which are compatible with the ordering and divisibility of monomials of $P$.

In this paper we propose a systematic study of the case when $\Sigma$ is generated by a single map $\sigma$. In this case the skew monoid ring $S$ coincides with the skew polynomial ring $P[s; \sigma]$ which is an Ore extension where $\sigma$-derivation is zero. The approach we follow is to consider an abstract map $\tau$ satisfying compatibility conditions able to provide a “natural” Gröbner bases theory. Note that this generalizes in particular the results contained in [30] where the map $\sigma : x_i \mapsto x_i^e$ with $e > 1$ has been studied. We choose to consider a single endomorphism essentially because a major application of our theory is the unification, in the graded case, of the Gröbner bases theory for non-commutative polynomials introduced in [15, 27, 29] with the classical commutative theory based on the notion of $S$-polynomial (see for instance [17]). In Section 6 we show in fact that there exists an algebra embedding $\iota : K\langle X \rangle \rightarrow S$ where $K\langle X \rangle$ is the free associative algebra generated by the variables $x_i$ and $S$ is the skew polynomial ring defined by the algebra $P$ of commutative polynomials in double indexed variables $x_{i}(j)$ and the endomorphism $\sigma : P \rightarrow P$ such that $x_{i}(j) \mapsto x_{i}(j+1)$, for all $i, j$. This algebra embedding is a significant improvement of the linear map $\iota' : K\langle X \rangle \rightarrow P$ defined as $x_{i_{1}} \cdots x_{i_{d}} \mapsto x_{i_{1}(1)} \cdots x_{i_{d}(d)}$ and introduced by [11, 7] for the aims of physics and invariant/representation theory. In fact, the use of the map $\iota$ clarifies the phenomenon found in [22] of a bijective correspondence between all graded two-sided ideals of $K\langle X \rangle$ and some class of $\Sigma$-invariant ideals of $P$. Note that in the same paper, a competitive new algorithm for non-commutative homogeneous Gröbner bases based on this correspondence has been implemented and experimented in SINGULAR [5].

In Section 2 one finds a brief account of the equivalence between the notion of $\Sigma$-invariant $P$-module and that of left $S$-module, together with the description of some properties of the generating sets of graded two-sided ideals of $S = \bigoplus S_i$ with $S_i = Ps^i$. A Gröbner basis theory for such ideals is introduced in Section 3 where we assume $P = K[x_0, x_1, \ldots], \Gamma = \langle \sigma \rangle$ and $\sigma : P \rightarrow P$ be a monomorphism of infinite order sending monomials into monomials. Additional assumptions for $\sigma$ are that $\gcd(\sigma(x_i), \sigma(x_j)) = 1$ for $i \neq j$ and the monomial ordering of $P$ is such that $m \prec n$ implies that $\sigma(m) \prec \sigma(n)$, for all monomials $m, n$. Such conditions are quite natural in many contexts as the shift operators defining difference ideals [23] or the maps used in [3]. Note that the algorithms we introduce for the computation of homogeneous Gröbner bases in $S$ are based on the free $P$-module structure of this ring and hence they appear as a variant of the classical module Buchberger
algorithm where the number of S-polynomials to be considered is reduced owing to the symmetry defined by Σ on the graded ideals of the ring S.

In Section 5 we analyze the notion of Gröbner Σ-basis for Σ-invariant ideals of P. When P can be endowed with a suitable grading compatible with the action of Σ, we describe a bijective correspondence between all graded Σ-invariant ideals of P and some class of graded two-sided ideals of S. Such correspondence preserves Gröbner bases and gives rise to a “duality” between homogeneous algorithms in P and in S. Note that for finitely generated ideals all these procedures admit termination when truncated at some degree. As we said earlier, in Section 6 the algebra embedding ι: K⟨X⟩ → S is introduced and a bijective correspondence between the ideals of K⟨X⟩ and suitable ideals of S is hence obtained by extension. The Gröbner bases are preserved by this correspondence and one obtains an alternative algorithm for computing non-commutative homogeneous Gröbner bases of K⟨X⟩ in the free P-module S. By means of the bijection of the Section 5, we reobtain in Section 7 the ideal correspondence and related algorithms introduced in [22] which provide the computation of non-commutative homogeneous Gröbner bases directly in P. Therefore, the theory for such bases can be deduced by the classical Buchberger algorithm for commutative polynomial rings. In Section 8 we propose the explicit computation of a finite Gröbner basis of an ideal of ordinary difference polynomials that can be obtained as a special case by the algorithms we introduced. Moreover, in this section we provide some timings obtained by an improvement of the library freegb.lib of SINGULAR initially developed for [22]. Finally, in Section 9 we propose some conclusions and suggestions for future developments of the theory of Gröbner Σ-bases and its methods.

The preliminary full-size version of this paper has been accepted for oral presentation at MEGA 2011 conference in Stockholm.

2. Modules over skew monoid rings

Fix K any field and let P be a commutative K-algebra. Let now Σ ⊂ End_K(P) a submonoid of the monoid of K-algebra endomorphisms of P. Denote S = P * Σ the skew monoid ring defined by Σ over P that is S is the free P-module with (left) basis Σ and the multiplication is defined by the identity σf = σ(f)σ, for all f ∈ P, σ ∈ Σ. If Σ ≠ {id} then S is a non-commutative K-algebra where the ring P and the monoid Σ are embedded. Note that if Σ = ⟨σ⟩ with σ : P → P a map of infinite order one has that S ≈ P[s; σ], the skew polynomial ring in the variable s and coefficients in P defined by the endomorphism σ. Moreover, if P is a domain and all maps in Σ are injective then S is also a domain. To simplify notations, we denote f^σ = σ(f) for any f ∈ P, σ ∈ Σ.

Definition 2.1. Let M be a P-module. We call M a Σ-invariant module if there is a monoid homomorphism ρ: Σ → End_K(M) such that ρ(σ)(fx) = f^σρ(σ)(x), for all f ∈ P, x ∈ M and σ ∈ Σ. We denote as usual σ · x = ρ(σ)(x). If M, M’ are Σ-invariant modules and ϕ : M → M’ is a P-module homomorphism such that ϕ(σ · x) = σ · ϕ(x) for all x ∈ M, σ ∈ Σ, then the map ϕ is called a homomorphism of Σ-invariant modules.

Proposition 2.2. The category of Σ-invariant P-modules is equal to the category of left S-modules.
Proof. Let $M$ be a left $S$-module. Then $M$ is a $P$-module since $P \subset S$. By restriction to $\Sigma \subset S$, one has a monoid homomorphism $\rho : \Sigma \rightarrow \text{End}_K(M)$. Moreover we have $\sigma \cdot (fx) = (\sigma f) \cdot x = (f^\sigma) \cdot x = f^\sigma(\sigma \cdot x)$, for all $f \in P, x \in M$ and $\sigma \in \Sigma$. Let now $M$ be a $\Sigma$-invariant $P$-module. We can define a left $S$-module structure by putting $(\sum_i f_i \sigma_i) \cdot x = \sum_i f_i (\sigma_i \cdot x)$ with $f_i \in P, \sigma_i \in \Sigma$ and $x \in M$. Consider a homomorphism $\varphi : M \rightarrow M'$ of $\Sigma$-invariant modules. Since $\varphi$ is $P$-linear, one has

$$\varphi((\sum_i f_i \sigma_i) \cdot x) = \sum_i f_i \varphi(\sigma_i \cdot x) = \sum_i f_i (\sigma_i \cdot \varphi(x)) = (\sum_i f_i \sigma_i) \cdot \varphi(x).$$

$$\square$$

Let $M$ be a left $S$-module and let $G = \{g_i\} \subset M$ be a generating set of $M$. Note that $x \in M$ if and only if $x = \sum f_i \sigma_i \cdot g_i$ with $f_\sigma \in P$ that is $M$ is generated by $\Sigma \cdot G = \{\sigma \cdot g_i\}_{i, \sigma}$ as $P$-module. We want now to describe homogeneous bases for graded two-sided ideals of $S$. In fact, the algebra $S$ has a natural grading over the monoid $\Sigma$ that is $S = \bigoplus_{\sigma \in \Sigma} S_\sigma$ and $S_\sigma S_\tau \subset S_{\sigma \tau}$ where $S_\sigma = P\sigma$. Note that $S_{id} = P$, all $S_\sigma$ are $P$-submodules of $S$ and $S_\sigma \tau = S_{\sigma \tau}$.

**Proposition 2.3.** Let $J \subset S$ be a graded (two-sided) ideal and let $G \subset J$ be a set of homogeneous elements. Then $G$ is a generating set of $J$ if and only if $G \Sigma$ is a left basis of $J$ that is $\Sigma G \Sigma$ is a basis of $J$ as $P$-module.

**Proof.** Assume $G = \{g_i\sigma_i\}$ with $g_i \in P, \sigma_i \in \Sigma$, for all $i$. Let $p_i, q_i \in S$ with $q_i = \sum \sigma q_{i\sigma} \sigma$ and $q_i \sigma \in P$. It is sufficient to note that $\sum p_i g_i \sigma_i q_i = \sum \sigma p_i g_i \sigma_i q_{i\sigma} \sigma = \sum_{i, \sigma} p_i q_{i\sigma}^\sigma g_i \sigma_i \sigma$.

$$\square$$

**Corollary 2.4.** Let $f, g \in S$ and let $g$ be a homogeneous element. Then, one has that $f = pgq$ with $p, q \in S$ if and only if $f$ belongs to the (graded) left ideal generated by $\{g\sigma\}_{\sigma \in \Sigma}$.

3. **Monomial orderings and Gröbner bases**

Denote $\mathbb{N} = \{0, 1, \ldots\}$ the set of non-negative integers and let $X = \{x_0, x_1, \ldots\}$ be a countable set. From now on, we make the assumption that $P = K[X]$ is a commutative polynomial ring in the variables set $X$. Starting from Section 6 we will assume in particular that this set has the form $X \times \mathbb{N}$. Moreover, we fix $\sigma : P \rightarrow P$ an algebra homomorphism of infinite order and define the monoid $\Sigma = \langle \sigma \rangle \approx \mathbb{N}$. Then, the skew monoid ring $S = P * \Sigma$ is isomorphic to the skew polynomial ring $P[s; \sigma]$ and we identify $\Sigma = \{\sigma^i\}$ with the monoid $\{s^i\}$ of powers of the variable $s$. Note that $S$ is a free $P$-module of infinite rank. We denote $f^s = f^{\sigma^i} = \sigma^i(f)$, for all $f \in P, i \geq 0$. Moreover, a homogeneous element $f \in S_i = Ps^i$ for some $i$ is also called $s$-homogeneous and we put $\deg_s(f) = i$. Note finally that in the theory of difference ideals [23], the ring $S$ is called ring of ordinary difference operators over $P$.

Denote by $\text{Mon}(P)$ the set of all monomials of $P$ (including 1). Clearly, $\text{Mon}(P)$ is a multiplicative $K$-basis of $P$ that is $mn \in \text{Mon}(P)$ for all $m, n \in \text{Mon}(P)$. By definition of $S$, a $K$-basis of such algebra is given by the elements $ms^i$ where $m \in \text{Mon}(P)$ and $i \geq 0$ is an integer. We call such elements the monomials of $S$ and we denote the set of them as $\text{Mon}(S)$. Clearly $\text{Mon}(P) \subset \text{Mon}(S)$. Note that $\text{Mon}(S)$ is in fact the “monomial basis” of $S$ as a free $P$-module.

In what follows, we assume also that the endomorphism $\sigma : P \rightarrow P$ is injective and monomial that is it stabilizes the set $\text{Mon}(P)$. In other words, $\{\sigma(x_i)\}$ is a set of algebraically independent monomials. Since $P$ is a domain, it follows that $S$ is also
a domain and the $K$-basis $\text{Mon}(S)$ is multiplicative since $ms^i\n s^j = mn^s i + j \neq 0$, for all $m,n \in \text{Mon}(P)$ and $i,j \geq 0$.

We want to study now some divisibility relations in $\text{Mon}(S)$. Let $f,g \in S$. We say that $f$ left-divides $g$ if there is $a \in S$ such that $g = af$. Clearly, left divisibility is a partial ordering (up to units). Since $\sigma$ is a monomial injective map, one has that if $f,g \in \text{Mon}(S)$ then also $a \in \text{Mon}(S)$.

**Proposition 3.1.** Let $v = ms^i, w = ns^j \in \text{Mon}(S)$ with $m,n \in \text{Mon}(P)$. Then $v$ left-divides $w$ if and only if $i \leq j$ and $m^{s^i} | n$.

**Proof.** Let $a = ps^k \in \text{Mon}(S)$ with $p \in \text{Mon}(P)$ such that $ns^j = ps^k ms^i = pm^s i s^{k+i}$. Then, we have that $j - i = k \geq 0$ and $m^s i | n$. \hfill $\Box$

Note that $S$ has also a free $P$-module structure and so $\text{Mon}(S)$ inherits another notion of divisibility. Precisely, let $v,w \in \text{Mon}(S)$. We say that $v$ $P$-divides $w$ if $\deg_s(v) = \deg_s(w)$ and there is $a \in \text{Mon}(P)$ such that $w = av$. Clearly $P$-divisibility is a partial ordering and one has the following result.

**Proposition 3.2.** Let $v,w \in \text{Mon}(S)$. Then $v$ left-divides $w$ if and only if $s^k v$ $P$-divides $w$ for some $k \geq 0$.

Note that left divisibility coincides with $P$-divisibility when the monomials have the same $s$-degree. If there are $v,w,a,b \in \text{Mon}(S)$ such that $w = avb$ we say that $v$ (two-sided) divides $w$. It is easy to prove that such divisibility is also a partial ordering.

**Proposition 3.3.** Let $v,w \in \text{Mon}(S)$. Then $w$ is a multiple of $v$ if and only if there is $j \geq 0$ such that $w$ is a left multiple of $vs^j$, that is $w$ is a $P$-multiple of $s^i vs^j$ for some $i,j \geq 0$.

**Proof.** Since monomials are $s$-homogeneous elements of $S$, by applying Corollary [2,4] we obtain that $w$ is a multiple of $v$ if and only if $w$ belongs to the (graded) left ideal generated by $\{vs^j\}_{j \geq 0}$. Clearly, this happens when $w$ is a left multiple of $vs^j$ for some $j$. \hfill $\Box$

We start now considering monomial orderings.

**Definition 3.4.** Let $\prec$ be a total ordering on the set $\text{Mon}(S)$. We call $\prec$ a monomial ordering of $S$ if it satisfies the following conditions

(i) $\prec$ is a well-ordering, that is every non-empty set of $\text{Mon}(S)$ has a minimal element;

(ii) $\prec$ is compatible with multiplication, that is if $v \prec w$ then $pvq \prec pwq$, for all $v,w,p,q \in \text{Mon}(S)$.

It follows immediately that $1 \preceq w$ for any $w \in \text{Mon}(S)$ and if $w = pvq$ with $p \neq 1$ or $q \neq 1$ then $v \prec w$ for all $v,w,p,q \in \text{Mon}(S)$. Note that the above conditions agree with general definitions of orderings on $K$-bases of associative algebras that provide a Gröbner basis theory (see for instance [16, 24]). The same conditions define monomial orderings of the free algebras $K\langle X \rangle$ and $K[X]$. Note that such algebras can be endowed with a monomial ordering even if the set of variables $X$ is countable. This is provided by the Higman’s lemma [19] which implies that any multiplicatively compatible total ordering of the monomials such that $1 \prec x_0 \prec x_1 \prec \ldots$ is a monomial ordering. Recall that $f^s$ stands for $\sigma(f)$ for any $f \in P$. 

Definition 3.5. Let $\prec$ be a monomial ordering on $P$. We call $\sigma$ compatible with $\prec$ if $\sigma$ is a strictly increasing map when restricted to $\text{Mon}(P)$, that is $m \prec n$ implies that $m^s \prec n^s$ for all $m, n \in \text{Mon}(P)$.

The following result is based essentially on Remark 3.2 in [3].

Proposition 3.6. Assume $\sigma$ be compatible with $\prec$. Then $\sigma$ is not an automorphism and $m \preceq m^s$, for all $m \in \text{Mon}(P)$.

Proof. Since $\sigma \neq \text{id}$, there is $m \in \text{Mon}(S)$ such that $m \neq m^s$. If $m \succ m^s$, by compatibility of $\sigma$ one gets an infinite descending chain $m \succ m^s \succ m^{s^2} \succ \ldots$ which contradicts the condition that $\prec$ is a well-ordering. We conclude that $m \prec m^s$.

Assume $\sigma$ has the inverse $\sigma^{-1}$. By applying $\sigma$, from $m^{s^{-1}} \prec n^{s^{-1}}$ it follows that $m \prec n$. Since $\sigma^{-1}$ is injective, we have therefore that $m \prec n$ implies that $m^{s^{-1}} \prec n^{s^{-1}}$. Now, by compatibility of $\sigma^{-1}$ we obtain $m \prec m^{s^{-1}}$ which contradicts $m \prec m^s$. \hfill \Box

There are many endomorphisms $\sigma$ with are compatible with usual monomial orderings on $P$ like lex, degrevlex, etc. For instance, we have the following maps.

- $\sigma(x_i) = x_{f(i)}$ for any $i$, where $f : \mathbb{N} \to \mathbb{N}$ is a strictly increasing map. Such maps have been considered in [3]. In particular, one may define the shift operator $\sigma(x_i) = x_{i+1}$ which is used in difference algebra.
- $\sigma(x_i) = x_i^e$ for any $i$, with $e > 1$. This map has been considered in [30].

Proposition 3.7. Let $\prec$ be a monomial ordering on $S$. Then $\sigma$ is compatible with the restriction of $\prec$ to $\text{Mon}(P)$. Moreover, for any $m, n \in \text{Mon}(P)$ and $i, j \geq 0$ one has that $ms^i \prec ns^i$ implies that $m \prec n$ or $i < j$.

Proof. Suppose $m \prec n$ with $m, n \in \text{Mon}(P)$. Then $sm \prec sn$ that is $ms^i \prec ns^i$. If $m^s \succeq n^s$ then $ms^i \prec ns^i$ which is a contradiction. We conclude that $m^s \prec n^s$.

Now, assume that $m \succeq n$ and $i \geq j$. We have $ms^i \succeq ms^j \succeq ns^j$.

Assume now $\sigma$ be compatible with a monomial ordering $\prec$ of $P$. We define a total ordering on $\text{Mon}(S)$ by putting $ms^i \prec' ns^j$ if and only if $i < j$, or $i = j$ and $m \prec n$, for all $m, n \in \text{Mon}(P)$ and $i, j \geq 0$. Clearly, the restriction of $\prec'$ to $\text{Mon}(P)$ is $\prec$.

Proposition 3.8. The ordering $\prec'$ is a monomial ordering on $S$ that extends $\prec$.

Proof. Clearly, an infinite descending sequence in $\text{Mon}(S)$ implies an infinite descending sequence in $\text{Mon}(P)$ which contradicts the condition that $\prec$ is a well-ordering. Let $ms^i, ns^j \in \text{Mon}(S)$ and suppose $ms^i \prec ns^j$ that is $i < j$, or $i = j$ and $m \prec n$. Let $qs^k \in \text{Mon}(S)$ and consider right multiplications $ms^iqs^k = mq^s^i s^{i+k}$ and $ns^iqs^k = nqs^i s^{i+k}$. If $i < j$ then $i + k < j + k$. If $i = j$ and $m \prec n$ then $mq^s^i \prec nqs^i = nqs^i$. We conclude in both cases that $mq^s^i s^{i+k} \prec nqs^i s^{i+k}$. For left multiplications $qs^km^s^i = qm^s^k s^{k+i}$ and $qs^kn^s^j = qn^s^k s^{k+j}$, note that $m \prec n$ implies that $m^s^k \prec n^s^k$. Then, one may argue in a similar way as for right multiplications. \hfill \Box

Clearly, a byproduct of Proposition 3.7 and Proposition 3.8 is that there exist monomial orderings on the skew polynomial ring $S$ if and only if $\sigma$ is compatible with a monomial ordering of $P$. Note that $\prec'$ is well-known as module ordering when we consider $S$ as a free $P$-module. Moreover, by Proposition 3.7 it follows
also that the monomial ordering of $S$ is uniquely defined by the one of $P$ when one compares monomials of the same s-degree.

From now on, we assume $S$ be endowed with a monomial ordering $\prec$.

**Definition 3.9.** Let $f \in S$, $f = \sum_i \alpha_i m_i s^i$ with $m_i \in \text{Mon}(P), \alpha_i \in K^*$. Then, we denote $\text{lm}(f) = m_k s^k = \max \{m_i s^i\}, \text{lct}(f) = \alpha_k$ and $\text{lt}(f) = \text{lct}(f) \text{lm}(f)$. If $G \subset S$ we put $\text{lm}(G) = \{\text{lm}(f) \mid f \in G, f \neq 0\}$. We denote as $\text{LM}(G)$ and $\text{LM}_i(G)$ respectively the two-sided ideal and the left ideal of $S$ generated by $\text{lm}(G)$. Moreover, we denote by $\text{LM}_P(G)$ the $P$-submodule of $S$ generated by $\text{lm}(G)$.

**Proposition 3.10.** Let $J$ be an ideal (respectively left ideal) of $S$. Then, the set $\{w + J \mid w \in \text{Mon}(S) \setminus \text{LM}(J)\}$ (resp. $\{w + J \mid w \in \text{Mon}(S) \setminus \text{LM}_i(J)\}$) is a $K$-basis of the space $S/J$. If $J \subset S$ is a $P$-submodule, in the same way one defines the $K$-basis $\{w + J \mid w \in \text{Mon}(S) \setminus \text{LM}_P(J)\}$.

**Proof.** Let $w \in \text{Mon}(S)$. By induction on the monomial ordering of $S$, we can assume that for any monomial $v \in \text{Mon}(S)$ such that $v \prec w$ there is a polynomial $f \in S$ belonging to the span of $N = \text{Mon}(S) \setminus \text{LM}(J)$ such that $v - f \in J$. If $w \notin N$ then there is $g \in J$ such that $w = pm(g)q$ with $p, q \in \text{Mon}(S)$. Therefore $f = w - (1/\text{lct}(g))pqg$ is such that $\text{lm}(f) \prec w$ and by induction $f - f' \in J$ for some $f' \in \langle N \rangle_K$. We conclude that $w - f' \in J$. Finally if $f \in N \cap J$ then necessarily $f = 0$. Mutatis mutandis one proves the remaining assertions. \qed

**Definition 3.11.** Let $J$ be an ideal (respectively left ideal) of $S$ and $G \subset J$. We call $G$ a Gröbner basis (resp. left basis) of $J$ if $\text{LM}(G) = \text{LM}(J)$ (resp. $\text{LM}_i(G) = \text{LM}_i(J)$). As usual, if $J$ is a $P$-submodule of $S$ then $G$ is a Gröbner $P$-basis of $J$ when $\text{LM}_P(G) = \text{LM}_P(J)$.

**Proposition 3.12.** Let $J$ be an ideal (respectively left ideal) of $S$ and $G \subset J$. The following conditions are equivalent:

(i) $G$ is a Gröbner basis (resp. left basis) of $J$;

(ii) for any $f \in J$, one has a Gröbner representation of $f$ with respect to $G$ that is $f = \sum_i f_i g_i h_i$ (resp. $f = \sum_i f_i g_i$) with $\text{lm}(f) \geq \text{lm}(f_i) \text{lm}(g_i) \text{lm}(h_i)$ (resp. $\text{lm}(f) \geq \text{lm}(f_i) \text{lm}(g_i)$) and $f_i, h_i \in S$, for all $i$.

A similar characterization holds for Gröbner $P$-bases.

**Proof.** It follows immediately by the reduction process which is implicit in the proof of Proposition 3.10. \qed

**Proposition 3.13.** Let $J$ be a graded ideal of $S$ and $G \subset J$ be a subset of s-homogeneous elements. The following conditions are equivalent:

(i) $G$ is a Gröbner basis of $J$;

(ii) $G \Sigma$ is a Gröbner left basis of $J$;

(iii) $\Sigma G \Sigma$ is a Gröbner $P$-basis of $J$.

**Proof.** Assume $G = \{g_i\}$ is a Gröbner basis of $J$ and put $d_i = \text{deg}_s(g_i)$. If $f \in J$ then one has $f = \sum_i f_i g_i h_i$ where $f_i, h_i \in S$ and $\text{lm}(f) \geq \text{lm}(f_i) \text{lm}(g_i) \text{lm}(h_i)$, for all $i$. Decompose $h_i = \sum_j h_{ij} s^j$ with $h_{ij} \in P$ for any $i, j$. Then, we have $\text{lm}(f) \geq \text{lm}(f_i) \text{lm}(g_i) \text{lm}(h_{ij}) s^j$, for all $i, j$. Since $\text{lm}(g_i)$ has s-degree $d_i$, one obtains $\text{lm}(f_i) \text{lm}(g_i) \text{lm}(h_{ij}) s^j = \text{lm}(f_i) \text{lm}(h_{ij}) s^{d_i} \text{lm}(g_i s^j)$. Moreover, as in Proposition 2.2 we have $f = \sum_{i,j} f_i g_i h_{ij} s^j = \sum_{i,j} f_i h^{s^{d_i}}_{ij} g_i s^j$. From $\sigma$ compatible with $\prec$ it follows
that $\text{lm}(h_{ij}^{x_i}) = \text{lm}(h_{ij})^{x_i}$ and hence $f$ has a left Gröbner representation with respect to $G \Sigma$, that is this set is a left Gröbner basis of $J$. The rest of the proof is straightforward.  

\section{Buchberger algorithm}

After Proposition 4.2 in order to obtain a homogeneous Gröbner basis $G$ of a (two-sided) graded ideal $J \subset S$ one has to start with a homogeneous generating set $H$ and consider the $P$-basis $H' = \Sigma H \Sigma$. Then, one should transform $H'$ into a homogeneous Gröbner $P$-basis $G'$ of $J$ and finally reduce $G'$ as $G' = \Sigma G \Sigma$ with $G \subset J$. Apart with problems concerning termination of the module Buchberger algorithm ($P$ is not Noetherian and $S$ is a $P$-module of countable rank) that we will show solvable for the truncated algorithm up to some $s$-degree (see Proposition 4.7), it is more desirable to have a procedure able to compute $G$ without actually considering all elements of $G'$. To obtain this, we need an additional requirement for the endomorphism $\sigma$.

Note that, since $\sigma : P \to P$ is a ring homomorphism, such map is increasing with respect to the divisibility relation in $P$, that is $f \mid g$ implies that $f^s \mid g^s$ and in this case $(g/f)^s = g^s/f^s$ with $f, g \in P$.

\textbf{Proposition 4.1.} The following conditions are equivalent:

(a) $\gcd(x_i^s, x_j^s) = 1$, for all $i \neq j$;
(b) $\gcd(m^s, n^s) = \gcd(m, n)^s$, for all $m, n \in \text{Mon}(P)$.

Moreover, in this case one has $m \mid n$ if and only if $m^s \mid n^s$ and $\text{lcm}(m^s, n^s) = \text{lcm}(m, n)^s$ with $m, n \in P$. In other words, $\sigma$ is a lattice homomorphism with respect to the divisibility relation in $\text{Mon}(P)$.

\textbf{Proof.} Assume (a) and let $m, n \in \text{Mon}(P)$ such that $\gcd(m, n) = 1$. If $m = x_{i_1} \cdots x_{i_k}$ and $n = x_{j_1} \cdots x_{j_l}$ then $m^s = x_{i_1}^s \cdots x_{i_k}^s$ and $n^s = x_{j_1}^s \cdots x_{j_l}^s$ with ${i_1, \ldots, i_k} \cap {j_1, \ldots, j_l} = \emptyset$. Since $\gcd(x_i^s, x_j^s) = 1$ for all $i \neq j$, we conclude that $\gcd(m^s, n^s) = 1$. Assume now $\gcd(m, n) = u$ and hence $\gcd(m/u, n/u) = 1$. Then $\gcd(m^s/u^s, n^s/u^s) = \gcd((m/u)^s, (n/u)^s) = 1$ and therefore $\gcd(m^s, n^s) = u^s$ that is (b) holds. Suppose $m^s \mid n^s$ that is $m^s = \gcd(m^s, n^s) = \gcd(m, n)^s$. Since $\sigma$ is injective we have that $m = \gcd(m, n)$ that is $m \mid n$. Moreover, one obtains $\text{lcm}(m, n)^s = (mn/\gcd(m, n))^s = (mn)^s/\gcd(m, n)^s = m^s n^s/\gcd(m^s, n^s) = \text{lcm}(m^s, n^s)^s$ for all $m, n \in \text{Mon}(P)$.  

\textbf{Definition 4.2.} We say that $\sigma$ is compatible with divisibility in $\text{Mon}(P)$ if for all $i \neq j$, one has $\gcd(x_i^s, x_j^s) = 1$ that is the variables occurring in the monomials $x_i^s, x_j^s$ are disjoint.

Note that if a monomial endomorphism of $P$ is compatible with divisibility then it is automatically injective since the monomials $x_i^s$ are algebraically independent. Let $\mid$ be the divisibility relation and $\prec$ a monomial ordering on $\text{Mon}(P)$. Throughout the rest of the paper, we make the assumption that the monomial endomorphism $\sigma : P \to P$ is compatible both with $\mid$ and with $\prec$.

We recall now some basic results in the theory of module Gröbner bases by applying them to the free $P$-module $S$ whose (left) free basis is $\Sigma = \{s_i\}_{i \geq 0}$. Consider $f, g \in S \setminus \{0\}$ two elements whose leading monomials have the same $s$-degree (component), that is $\text{lm}(f) = ms^i, \text{lm}(g) = ns^i$ with $m, n \in \text{Mon}(P)$ and $i \geq 0$. If we put $\text{lc}(f) = \alpha, \text{lc}(g) = \beta$ and $l = \text{lcm}(m, n)$, one defines the
S-polynomial \( \text{spoly}(f, g) = (1/\alpha_m)f - (1/\beta_n)g \). Clearly \( \text{spoly}(f, g) = -\text{spoly}(g, f) \) and \( \text{spoly}(f, f) = 0 \).

**Proposition 4.3** (Buchberger criterion). Let \( G \) be a generating set of a \( P \)-submodule \( J \subset S \). Then \( G \) is a Gröbner basis of \( J \) if and only if for all \( f, g \in G \setminus \{0\} \) such that \( \deg_s(\text{lm}(f)) = \deg_s(\text{lm}(g)) \), the S-polynomial \( \text{spoly}(f, g) \) has a Gröbner representation with respect to \( G \).

Usually the above result, see for instance [10, 17], is stated when \( P \) is a polynomial ring with a finite number of variables and \( S \) is a \( P \)-module of finite rank. In fact such assumptions are not needed since Noetherianity is not used in the proof, but only the existence of a monomial ordering for the ring \( P \) and the free module \( S \). See also the comprehensive Bergman’s paper [2] where the “Diamond Lemma” is proved without any restriction on the finiteness of the variable set. In the following results we show how the Buchberger criterion, and hence the corresponding algorithm, can be reduced up to the symmetry defined by the monoid \( \Sigma \) on \( S \).

**Lemma 4.4.** Let \( f, g \in S \setminus \{0\} \) and let \( i \leq j \) such that \( \deg_s(\text{lm}(f)) + i = \deg_s(\text{lm}(g)) + j \). Then \( \text{spoly}(s^i f, s^j g) = s^i \text{spoly}(f, s^{j-i} g) \) and \( \text{spoly}(f s^i, g s^j) = \text{spoly}(f, g s^{j-i}) s^i \).

**Proof.** Let \( \text{lt}(f) = \alpha m^s f, \text{lt}(g) = \beta n^s g \) with \( \alpha, \beta \in K^* \) and \( m, n \in \text{Mon}(P) \). Then \( \text{lt}(s^i f) = \alpha m^s s^{i+k}, \text{lt}(s^j g) = \beta n^s s^{j+l} \) and \( \text{lt}(s^{j-i} g) = \beta n^{s^{j-i}} s^{j-i+l} \). By compatibility of \( \sigma \) with divisibility in \( \text{Mon}(P) \), if \( q = \text{lcm}(m, n^{s^{j-i}}) \) then \( \text{lcm}(m^s, n^s) = q^s \).

Therefore \( h = \text{spoly}(f, s^{j-i} g) = (q/\alpha m) f - (q/\beta n^{s^{j-i}}) s^{j-i} g \) and hence we have \( h s^i = (q/\alpha m^s) f s^i - (q/\beta n^{s^{j-i}}) s^{j-i} g = \text{spoly}(f s^i, g s^j) \).

Note now that \( \text{lt}(f s^i) = \alpha m^s s^{i+k}, \text{lt}(g s^j) = \beta n^{s^{j+i}} s^{j+l} \) and \( \text{lt}(g s^{j-i}) = \beta n^{s^{j-i}} s^{j-i+l} \). If \( q = \text{lcm}(m, n) \) and \( h = \text{spoly}(f, g s^j) = (\alpha m^s f - (q/\beta n) g s^j) \) we have simply that \( h s^i = (q/\alpha m^s) f s^i - (q/\beta n) g s^j = \text{spoly}(f s^i, g s^j) \). \( \square \)

**Proposition 4.5** (Two-sided \( \Sigma \)-criterion). Let \( G \) be an \( s \)-homogeneous basis of a graded two-sided ideal \( J \subset S \). Then \( G \) is a Gröbner basis of \( J \) if and only if for all \( f, g \in G \setminus \{0\} \) and for any \( i, j \geq 0 \), the S-polynomials \( \text{spoly}(f, s^i g s^j) \) (\( \deg_s(f) = \deg_s(g) + i + j \)) and \( \text{spoly}(f s^i, g s^j) \) (\( \deg_s(f) + i = \deg_s(g) + j \)) have a Gröbner representation with respect to \( \Sigma G \Sigma \).

**Proof.** By Proposition 3.13 we have to prove that \( G' = \Sigma G \Sigma \) is a Gröbner basis of \( J \) as \( P \)-module, that is \( G' \) is \( P \)-basis of \( J \) and the S-polynomials \( h = \text{spoly}(s^i f s^k, s^j g s^l) \) have a Gröbner representation with respect to \( G' \) for all \( f, g \in G \setminus \{0\} \) and for any \( i, j, k, l \geq 0 \) such that \( \deg_s(f) + i + k = \deg_s(g) + j + l \). Since \( G \) is a homogeneous basis of \( J \) as two-sided ideal, from Proposition 3.3 it follows that \( G' \) is a generating set of \( J \) as \( P \)-module. Consider now all possibilities \( i \leq j \) or \( i \geq j \) and \( k \leq l \) or \( k \geq l \) and apply Lemma 4.4. If \( i < j, k < l \) one has \( h = s^i \text{spoly}(f, s^{j-i} g s^{l-k}) s^k \), if \( i \leq j, k \geq l \) then \( h = s^i \text{spoly}(f s^{j-k}, s^{j-i} g) s^l \), and so on. Then, assume that \( h = \text{spoly}(f, g) \), with \( f, g \in G' \setminus \{0\} \), has a Gröbner representation with respect to \( G' \) as \( P \)-basis of \( J \), that is \( h = \sum_i f_i g_i \) with \( f_i \in P, g_i \in G' \) and \( \text{lm}(h) \geq \text{lm}(f_i) \text{lm}(g_i) \), for all \( i \). We have to prove that \( s^k h s^i \) has also a Gröbner representation with respect to \( G' \) for any \( k, l \geq 0 \). One has that \( s^k h s^i = \sum_i f_i s^k g_i s^l \) and \( \text{lm}(s^k h s^i) = s^k \text{lm}(h) s^l \geq s^k \text{lm}(f_i) \text{lm}(g_i) s^l = \text{lm}(f_i) s^k s^l \text{lm}(g_i) s^l = \text{lm}(f_i) s^k \text{lm}(g_i) \text{lm}(s^k g_i s^l) \). Since \( s^k g_i s^l \in G' = \Sigma G \Sigma \), one obtains that \( s^k h s^i \) has a Gröbner representation with respect to \( G' \). \( \square \)
A criterion similar to Proposition 4.5 holds clearly for Gröbner left bases of left ideals of $S$ where no restrictions about the $s$-homogeneity of bases and ideals are needed.

**Proposition 4.6 (Left Σ-criterion).** Let $G$ be a basis of a left ideal $J \subset S$. Then $G$ is a Gröbner basis of $J$ if and only if for all elements $f, g \in G \setminus \{0\}$ such that $i = \deg_s(lm(f)) - \deg_s(lm(g)) \geq 0$, the $S$-polynomial $spoly(f, s^i g)$ has a Gröbner representation with respect to $\Sigma G$.

A standard procedure in the (module) Buchberger algorithm is the following.

**Algorithm 4.1 Reduce**

Input: $f \in S$ and $G \subset S$.
Output: $h \in S$ such that $f - h \in \langle G \rangle_P$ and $h = 0$ or $\text{lm}(h) \notin \text{LM}_P(G)$.

$h := f$;

while $h \neq 0$ and $\text{lm}(h) \in \text{LM}_P(G)$ do

choose $g \in G, g \neq 0$ such that $\text{lm}(g)$ $P$-divides $\text{lm}(h)$;

$h := h - (\text{lt}(h)/\text{lt}(g))g$;

end while;

return $h$.

Note that if $\text{lt}(g) = \alpha ms^i, \text{lt}(h) = \beta ns^i$ with $\alpha, \beta \in K^*$ and $m, n \in \text{Mon}(P)$, by definition $\text{lt}(h)/\text{lt}(g) = (\alpha m)/(\beta n)$. Moreover, the termination of Reduce is provided since $\prec$ is a well-ordering on $\text{Mon}(S)$. In particular, even if $G$ is an infinite set, there are only a finite number of elements $g \in G, g \neq 0$ such that $\text{lm}(g)$ $P$-divides $\text{lm}(h)$ and hence $\text{lm}(g) \preceq \text{lm}(h)$.

It is well-known that if $\text{Reduce}(f, G) = 0$ then $f$ has a Gröbner representation with respect to $G$. Moreover, if $\text{Reduce}(f, G) = h \neq 0$ then clearly we have $\text{Reduce}(f, G \cup \{h\}) = 0$. Therefore, from Proposition 4.5 it follows immediately the correctness of the following algorithm.
Algorithm 4.2 SkewGBasis

Input: \( H \), an \( s \)-homogeneous basis of a graded two-sided ideal \( J \subset S \).
Output: \( G \), an \( s \)-homogeneous Gröbner basis of \( J \).

\[
G := H; \\
B := \{(f, g) \mid f, g \in G\}; \\
\text{while } B \neq \emptyset \text{ do} \\
\quad \text{choose } (f, g) \in B; \\
\quad B := B \setminus \{(f, g)\}; \\
\quad \text{for all } i, j \geq 0 \text{ such that } i + j = \deg_s(f) - \deg_s(g) \text{ do} \\
\quad \quad h := \text{Reduce}(\text{spoly}(f, g), \Sigma G \Sigma); \\
\quad \quad \text{if } h \neq 0 \text{ then} \\
\quad \quad \quad B := B \cup \{(h, h), (h, k), (k, h) \mid k \in G\}; \\
\quad \quad \quad G := G \cup \{h\}; \\
\quad \quad \text{end if;} \\
\quad \text{end for;} \\
\quad \text{for all } i, j \geq 0 \text{ such that } j - i = \deg_s(f) - \deg_s(g) \text{ do} \\
\quad \quad h := \text{Reduce}(\text{spoly}(f^i, g^j), \Sigma G \Sigma); \\
\quad \quad \text{if } h \neq 0 \text{ then} \\
\quad \quad \quad B := B \cup \{(h, h), (h, k), (k, h) \mid k \in G\}; \\
\quad \quad \quad G := G \cup \{h\}; \\
\quad \quad \text{end if;} \\
\quad \text{end for;} \\
\text{end while;} \\
\text{return } G.
\]

Clearly, all well-known criteria (product criterion, chain criterion, etc) can be applied to SkewGBasis to shorten the number of \( S \)-polynomials to be considered. In fact, this algorithm can be understood as the usual (module) Buchberger procedure applied to the \( P \)-basis \( \Sigma H \Sigma \), where an additional criterion to avoid “useless pairs” is provided by Proposition 4.5. Note that owing to Proposition 4.6, one has also a similar procedure for computing a Gröbner left basis of any left ideal of \( S \). Since the set \( \Sigma H \Sigma \) if infinite even if the basis \( H \) is eventually finite (\( S \) is a non-Noetherian ring) one has that SkewGBasis does not admit general termination. In particular, the cycle “for all \( i, j \geq 0 \) such that \( j - i = \deg_s(f) - \deg_s(g) \) do” never stops unless one bounds the \( s \)-degree \( \deg_s(f) + i = \deg_s(g) + j \). As for other non-Noetherian structures like the free associative algebra that in fact can be embedded in \( S \) (see Section 6), the termination of homogeneous Gröbner bases computations can be obtained only under truncation.

Proposition 4.7. Let \( J \subset S \) be a graded two-sided ideal and fix \( d \geq 0 \). Assume that \( J \) has a \( s \)-homogeneous basis \( H \) such that \( H_d = \{f \in H \mid \deg_s(f) \leq d\} \) is a finite set. Then, there exists an \( s \)-homogeneous Gröbner basis \( G \) of \( J \) such that \( G_d \) is also finite. In other words, if we consider a selection strategy for the \( S \)-polynomials based on their \( s \)-degree, we obtain that the \( d \)-truncated version of the algorithm SkewGBasis terminates in a finite number of steps.

Proof. Denote \( H'_d = \{s^if^j \mid f \in H_d, i, j \geq 0, i + j + \deg_s(f) \leq d\} \). Since \( H_d \) is finite one has that \( H'_d \) is also finite. Then, consider \( X_d \) the finite set of variables of \( P \) occurring in the elements of \( H'_d \) and define \( P^{(d)} = K[X_d] \) and \( S^{(d)} = \bigoplus_{i \leq d} P^{(d)} s^i \).
In fact, the $d$-truncated algorithm SKEWGB basis computes a subset of a Gröbner basis of the $P^{(d)}$-submodule $J^{(d)} \subseteq S^{(d)}$ generated by $H_f$. By Noetherianity of the ring $P^{(d)}$ and the free $P^{(d)}$-module $S^{(d)}$ which has finite rank, we clearly obtain termination. 

Note that the above result implies algorithmic solution of the membership problem for graded ideals of $S$ which are finitely generated up to any degree.

5. $\Sigma$-invariant ideals of $P$

In this section we define Gröbner bases of $\Sigma$-invariant ideals $I \subseteq P$ which generates $I$ up to the action of $\Sigma$. Moreover, if $P$ can be endowed with a suitable grading, we show how such bases can be computed in the algebra $S$ for a class of graded $\Sigma$-invariant ideals. As usual, we fix a monomial endomorphism $\sigma : P \to P$ which is compatible both with the divisibility and a monomial ordering on $\text{Mon}(P)$ and we extend this to an ordering on $\text{Mon}(S)$. From Section 2 we know that $\Sigma$-invariant ideals of $P$ are just left $S$-submodules of $P$. Since we make use of identification $\Sigma = \{s^i\}$, for all $f \in P \subset S$ and for any $i \geq 0$ one has that $s^i \cdot f = f^* = \sigma_i(f)$ and $s^i f = (s^i \cdot f)s^i$.

**Definition 5.1.** Let $I \subseteq P$ be a $\Sigma$-invariant ideal and $G \subseteq I$. We say that $G$ is a $\Sigma$-basis of $I$ if $G$ is a basis of $I$ as left $S$-module. In other words, $\Sigma \cdot G$ is a basis of $I$ as $P$-ideal.

**Proposition 5.2.** Let $G \subseteq P$. Then $\text{lm}((\Sigma \cdot G)) = \Sigma \cdot \text{lm}(G)$. In particular, if $I$ is a $\Sigma$-invariant $P$-ideal then $\text{LM}_P(I)$ is also $\Sigma$-invariant.

**Proof.** Since $\sigma$ is compatible with the monomial ordering of $P$, it is sufficient to note that $\text{lm}(s^i \cdot f) = s^i \cdot \text{lm}(f)$ for any $f \in P$ and $i \geq 0$. □

**Definition 5.3.** Let $I \subseteq P$ be a $\Sigma$-invariant ideal and $G \subseteq I$. We call $G$ a Gröbner $\Sigma$-basis of $I$ if $\text{lm}(G)$ is a basis of $\text{LM}_P(I)$ as left $S$-module. In other words, $\Sigma \cdot G$ is a Gröbner basis of $I$ as $P$-ideal.

The computation of Gröbner $\Sigma$-bases of $\Sigma$-invariant $P$-ideals is relevant, for instance, in applications to difference algebra (cf. [23], Chapter 3). Such computations appear also in other contexts, see for instance [9] and [3]. Note that in the latter paper Gröbner $\Sigma$-bases are named “equivariant Gröbner bases”.

In analogy with Proposition 4.5 and Proposition 4.6 we present here a $\Sigma$-criterion that allows to reduce the number of $S$-polynomials to be checked to provide that a $\Sigma$-basis is of Gröbner type.

**Proposition 5.4 (\(\Sigma\)-criterion in $P$).** Let $G$ be a $\Sigma$-basis of a $\Sigma$-invariant ideal $I \subseteq P$. Then $G$ is a Gröbner $\Sigma$-basis of $I$ if and only if for all $f, g \in G \setminus \{0\}$ and for any $i \geq 0$, the $S$-polynomial $\text{spoly}(f, s^i \cdot g)$ has a Gröbner representation with respect to $\Sigma \cdot G$.

**Proof.** Consider any pair of elements $s^i \cdot f, s^j \cdot g \in \Sigma \cdot G$ ($f, g \in G$) and let $i \leq j$. By compatibility of $\sigma$ with divisibility in $\text{Mon}(P)$ (cf. Lemma 4.4), one has that $\text{spoly}(s^i \cdot f, s^j \cdot g) = s^i \cdot \text{spoly}(f, s^{j-i} \cdot g)$ with $k = j - i$. Assume that $\text{spoly}(f, s^k \cdot g) = h = \sum f_i(s^j \cdot g_i)$ ($f_i \in P, g_i \in G$) is a Gröbner representation with respect to $\Sigma \cdot G$. Since the endomorphism $\sigma$ is compatible with the monomial ordering of $P$, we have also the Gröbner representation $\text{spoly}(s^i \cdot f, s^j \cdot g) = s^i \cdot h = \sum (s^i \cdot f_i)(s^{i+l} \cdot g_i)$. □
Note that some version of this criterion can be found in [3], Theorem 2.5, where it is called “equivariant Buchberger criterion”. Before than this, the same ideas have been used in [22] for the Proposition 3.11. From this criterion it follows immediately the correctness of the following algorithm.

**Algorithm 5.1 SigmaGBasis**

Input: $H$, a $\Sigma$-basis of a $\Sigma$-invariant ideal $I \subset P$.
Output: $G$, a Gröbner $\Sigma$-basis of $I$.

1. $G := H$;
2. $B := \{(f, g) \mid f, g \in G\}$;
3. while $B \neq \emptyset$ do
   1. choose $(f, g) \in B$;
   2. $B := B \setminus \{(f, g)\}$;
   3. for all $i \geq 0$
      1. $h := \text{Reduce}(\text{spoly}(f, s^i \cdot g), \Sigma \cdot G)$;
      2. if $h \neq 0$ then
         1. $B := B \cup \{(h, h), (h, k), (k, h) \mid k \in G\}$;
         2. $G := G \cup \{h\}$;
      end if;
   end for;
4. end while;
5. return $G$. 
As for the algorithm SkewGBasis, all criteria to avoid useless pairs can be added to SigmaGBasis. Note that termination of this algorithm is not provided in general (note the infinite cycle “for all \( i \geq 0 \) do”) and this is, in fact, one of the main problems in applications to differential/difference algebra. Nevertheless, in what follows we describe some class of \( \Sigma \)-invariant ideals of \( P \) where a truncated version of the algorithm SigmaGBasis stops in a finite number of steps. Such ideals are in bijective correspondence with a class of graded (two-sided) ideals of \( S \) which have truncated termination of SkewGBasis provided by Proposition 4.7.

Consider now the \( P \)-module homomorphism \( \pi : S \to P \) such that \( s^i \mapsto 1 \), for all \( i \). Clearly \( \pi \) is a left \( S \)-module epimorphism whose kernel is the left ideal of \( S \) generated by \( s - 1 \).

**Definition 5.5.** Let \( J \) be a graded ideal of \( S \) and put \( J^P = \pi(J) \). Clearly \( J^P \) is a \( \Sigma \)-invariant ideal of \( P \).

**Proposition 5.6.** Let \( J \subset S \) be a graded ideal. If \( G \) is a homogeneous basis of \( J \) then \( G^P = \pi(G) \) is a \( \Sigma \)-basis of \( J^P \).

**Proof.** Since the map \( \pi \) is a left \( S \)-module homomorphism, it is sufficient to note that \( G \Sigma \) is a left basis of \( J \) and \( \pi(G \Sigma) = \pi(G) = G^P \).

We introduce now a grading on the algebra \( P \) which is compatible with action of \( \Sigma \). We start extending the structure \((\mathbb{N}, \max, +)\) in the following way.

**Definition 5.7.** Let \(-\infty \) be an element disjoint by \( \mathbb{N} \) and put \( \hat{\mathbb{N}} = \{-\infty\} \cup \mathbb{N} \). Then, we define a commutative idempotent monoid \((\hat{\mathbb{N}}, \max)\) with identity \(-\infty \) that extends \((\mathbb{N}, \max)\) (with identity 0) by imposing that \( \max(-\infty, x) = x \) for any \( x \in \hat{\mathbb{N}} \). Moreover, we define a commutative monoid \((\hat{\mathbb{N}}, +)\) with identity \(-\infty \) extending the monoid \((\mathbb{N}, +)\) by putting \(-\infty + x = -\infty \), for all \( x \in \hat{\mathbb{N}} \). Since \( + \) clearly distributes over \( \max \), one has that \((\hat{\mathbb{N}}, \max, +)\) is a commutative idempotent semiring, also known as commutative dioid or max-plus algebra [14].

Note that if \( \sigma^{-\infty} \in \text{End}_K(P) \) is the map such that \( x_i \mapsto 0 \) for any \( x_i \in X \), then \( \Sigma = \{ \sigma^{-\infty}\} \cup \Sigma \) is a commutative monoid isomorphic to \((\hat{\mathbb{N}}, +)\). Denote now \( M = \text{Mon}(P) \) the set of monomials of the polynomial ring \( P \).

**Definition 5.8.** A mapping \( w : M \to \hat{\mathbb{N}} \) such that for all \( m, n \in M \) and \( x_i \in X \) one has

(i) \( w(1) = -\infty \);

(ii) \( w(mn) = \max(w(m), w(n)) \);

(iii) \( w(s \cdot x_i) = 1 + w(x_i) \).

is called a weight function of \( P \) endowed with \( \sigma \).

Note that if \( m = x_{i_1} \cdots x_{i_j} \neq 1 \) with \( w(x_{i_1}) \leq \cdots \leq w(x_{i_j}) \) then \( w(m) = w(x_{i_j}) \). Moreover, the condition (iii) implies that \( w(s^i \cdot m) = i + w(m) \) for all \( i \in \hat{\mathbb{N}}, m \in M \) and hence \( s^i \cdot m = m \) if and only if \( m = 1 \) or \( i = 0 \). We put \( M_i = \{ m \in M \mid w(m) = i \} \) for all \( i \in \hat{\mathbb{N}} \) and define \( P_i \subset P \) the subspace spanned by \( M_i \). We have that \( P_{-\infty} = K \). Clearly \( P = \bigoplus_{i \in \hat{\mathbb{N}}} P_i \) is a grading of the algebra \( P \) defined by the monoid \((\hat{\mathbb{N}}, \max)\) by means of the function \( w \). Then, an element \( f \in P_i \) is said \( w \)-homogeneous of weight \( i \).

In what follows, we assume that \( P \) is endowed with a weight function. In fact, such functions are easily to define. Consider for instance the polynomial ring \( P =
K[X × N] and denote $x_i(j)$ each variable $(x_i, j) \in X \times N$. Let $\sigma : P \to P$ be the algebra monomorphism of infinite order such that $\sigma(x_i(j)) = x_i(j + 1)$, for all $i, j$. Clearly $\sigma$ is a monomial map compatible with divisibility in $\text{Mon}(P)$ and many usual monomial orderings on $P$, like lex, degrevlex, etc, are compatible with $\sigma$. For the algebra $P$ endowed with the map $\sigma$ we can clearly define the weight function $w(x_i(j)) = j$. In Section 6 we show how to embed the free associative algebra $K\langle X \rangle$ into the skew polynomial ring defined by $P$ and the monoid $\Sigma = \langle \sigma \rangle$.

Moreover, if we put $x_i(j) = \sigma^j(u_i)$ where $x_i(0) = u_i = u_i(t)$ is a set of (algebraically independent) univariate functions and $\sigma$ is the shift operator $u_i(t) \mapsto u_i(t + h)$ then $P = K[X \times N]$ is by definition the \textit{ring of ordinary difference polynomials} with constant coefficients in the field $K$ (see [23]). Such algebra is used to study systems of \textit{(ordinary) difference equations} for applications in combinatorics or discretization of systems of differential equations.

**Definition 5.9.** Let $I$ be an ideal of $P$. We call $I$ \textit{w-graded} if $I = \sum_i I_i$ with $I_i = I \cap P_i$ for any $i \in \mathbb{N}$.

Define now the skew monoid ring $\hat{S} = P * \hat{\Sigma}$ extending $S = P * \Sigma$ and let $\hat{\pi} : \hat{S} \to P$ the left $\hat{S}$-module epimorphism extending $\pi$ that is $s^i \mapsto 1$, for all $i \in \mathbb{N}$. The existence of a weight function for $P$ implies that one has also a mapping $\xi : P \to \hat{S}$ such that $\hat{\pi} \xi = \text{id}$.

**Proposition 5.10.** Define $\xi : P \to \hat{S}$ the homogeneous injective map such that $f \mapsto \sum_{i \in \mathbb{N}} f_i s^i$, for all $f = \sum_{i \in \mathbb{N}} f_i \in P$. Then $\xi$ is a $\Sigma$-equivariant map.

**Proof.** For all $i, j \in \mathbb{N}$ and $f \in P_j$ one has that $s^i \cdot f \in P_{i+j}$ and therefore $\xi(s^i \cdot f) = (s^i \cdot f)s^{i+j} = s^j fs^i = s^i \xi(f)$. \hfill $\square$

Let $I \subseteq P$ be a $\Sigma$-invariant ideal and consider $\xi(I) \subseteq \hat{S}$. Note that if $I \neq P$ then $I_{-\infty} = 0$ and the set $\xi(I)$ is in fact contained in $S$. Then, to get rid of the symbol $-\infty$ we restrict ourselves to ideals not containing constants.

**Definition 5.11.** Let $I \subseteq P$ be a $\Sigma$-invariant ideal of $P$. Denote by $I^S$ the graded (two-sided) ideal of $S$ generated by $\xi(I) \subseteq S$. In other words, if we put $G = \{f \in I_i | i \geq 0\}$ then $I^S$ is the left ideal generated by $G \Sigma = \{f s^i \in I_i | i \geq 0\}$ or equivalently $I^S$ has the basis $G \Sigma = \Sigma G \Sigma$ as $P$-submodule of $S$. We call $I^S$ the skew analogue of $I$.

**Proposition 5.12.** Let $I \subseteq P$ be a $\Sigma$-invariant ideal. Then $I^{SP} = I$, that is there is a bijective correspondence between all $\Sigma$-invariant ideals different from $P$ and their skew analogues in $S$.

**Proof.** Put $J = I^{SP} = \pi(I^S)$. For any $f \in I_i$ and $j \geq i$ we have clearly $\pi(f s^j) = f$.

Since the elements $f s^j$ are a left basis of $I^S$, the ideal $I$ is $\Sigma$-invariant and $\pi$ is a left $S$-module homomorphism, we have that $J \subseteq I$. Moreover, the elements $f \in I_i$ are a basis of $I = \sum_i I_i$ and one has also that $I \subseteq J$. \hfill $\square$

The next propositions need the following lemmas.

**Lemma 5.13.** If $s^k \cdot m$ divides $n$, with $m, n \in M$, then $w(n) - k \geq w(m)$.

**Proof.** Since $n = q(s^k \cdot m)$ with $q \in M$, we have $w(n) \geq w(s^k \cdot m) = k + w(m)$. \hfill $\square$

**Lemma 5.14.** Let $m, n \in M$ and put $l = \text{lcm}(m, n)$. Then, one has that $w(l) = \max(w(m), w(n))$. 

Proposition 5.15. Let \( I \subseteq P \) be a \( w \)-graded \( \Sigma \)-invariant ideal, then \( I^S \) is a graded ideal of \( S \). Let \( G = \bigcup_i G_i \) be a \( w \)-homogeneous \( \Sigma \)-basis of \( I \) that is \( G_i \subseteq I_i \). Then \( G^S = \xi(G) = \{ fs^i \mid f \in G_i, i \geq 0 \} \) is an \( s \)-homogeneous basis of \( I^S \).

Proof.
Consider the elements \( fs^i \) with \( f \in I_i, j \geq i \) which form a left basis of \( I^S \).
Since \( G \) is a \( \Sigma \)-basis, one has \( f = \sum_k f_k(s^k \cdot g_k) \) with \( f_k \in P, g_k \in G_i \).
From \( w(f) = i \), by Lemma 5.13, we obtain that \( i - k \geq i_k \).
We have therefore that \( fs^i = \sum_k f_k(s^k \cdot g_k)s^k s^{j-k} = \sum_k f_k s^k(g_k s^{j-k}) \) with \( j - k \geq i - k \geq i_k \) and hence \( g_k s^{j-k} \in G^S \), for all \( k \).

Note now that by Proposition 5.17, we have that \( ms^i \prec ns^i \) if and only if \( m < n \), for all \( m, n \in M \) and for any \( i \geq 0 \). In other words, if \( fs^i (f \in P) \) is an \( s \)-homogeneous element of \( S \) then \( \text{lm}(fs^i) = \text{lm}(f)s^i \).

Lemma 5.16. Let \( I \subseteq P \) be a \( w \)-graded \( \Sigma \)-invariant ideal.
If \( G = \bigcup_i I_i \), by definition \( I^S \) is the graded ideal of \( S \) generated by \( G^S = \xi(G) \). Then \( G^S \) is an \( s \)-homogeneous Gröbner basis of \( I^S \).

Proof.
Let \( fs^i, gs^j \in G^S \) is that the \( w \)-homogeneous elements \( f, g \in G \) are such that \( i \geq w(f), j \geq w(g) \).
Assume \( i \geq j \) and put \( k = i - j \). By Proposition 4.6, we have to check for Gröbner representations of the \( S \)-polynomial \( \text{spoly}(fs^i, s^k gs^j) \) with respect to \( \Sigma G^S \).
Since \( G \) is clearly a Gröbner \( \Sigma \)-basis of \( I \), one has that the \( S \)-polynomial \( \text{spoly}(f, s^k \cdot g) \) has a Gröbner representation with respect to \( \Sigma G \), say \( h = \text{spoly}(f, s^k \cdot g) = \sum f_i(s^i \cdot g_i) \) with \( f_i \in P, g_i \in G \).
Note that \( \text{spoly}(fs^i, s^k gs^j) = hs^i = \sum f_is^i(s^i \cdot g_i)s^j \).
We have to prove now that \( i \geq l + w(g_i) \) for any \( l \), because in this case, one has the Gröbner representation \( hs^i = \sum f_is^i(g_is^{j-l}) \).
In fact, by Lemma 5.13 and Lemma 5.14, we have that \( \max(w(f), w(g)) = w(h) = l + w(g_i) \).
Then, from \( i \geq w(f) \) and \( i \geq j \), one obtains the claim.

Proposition 5.17. Let \( G \subseteq \bigcup_{i \geq 0} I_i \). Then \( \text{lm}(G)^S = \text{lm}(G^S) \).
Moreover, if \( I \subseteq P \) is a \( w \)-graded \( \Sigma \)-invariant ideal then \( \text{LM}_P(I)^S = \text{LM}(I^S) \).

Proof.
If \( f \in P_i \) is a \( w \)-homogeneous element then \( w(\text{lm}(f)) = w(f) = i \) and \( \text{lm}(f)s^i = \text{lm}(fs^i) \).
We obtain that \( \text{lm}(G)^S = \text{lm}(G^S) \).
Consider now \( G = \bigcup_i I_i \).
By definition \( I^S \) is the ideal of \( S \) generated by \( G^S \).
Moreover, since \( I = \bigcup_i I_i \) one has that \( \text{lm}(G) = \text{lm}(I) \) and hence \( \text{LM}_P(I)^S \) is the ideal generated by \( \text{lm}(G)^S = \text{lm}(G^S) \).
Finally, by Lemma 5.16 one has that \( \text{LM}(I^S) \) is the ideal of \( S \) generated by \( \text{lm}(G^S) \).

Proposition 5.18. Let \( I \subseteq P \) be a \( w \)-graded \( \Sigma \)-invariant ideal. Let \( G = \bigcup_i G_i \) be a \( w \)-homogeneous Gröbner \( \Sigma \)-basis of \( I \). Then, \( G^S = \xi(G) \) is an \( s \)-homogeneous Gröbner basis of \( I^S \).

Proof.
By hypothesis \( \text{lm}(G) \) is a \( \Sigma \)-basis of \( \text{LM}_P(I) \).
Then \( \text{lm}(G^S) = \text{lm}(G)^S \) is a basis of \( \text{LM}_P(I)^S = \text{LM}(I^S) \) that is \( G^S \) is a Gröbner basis of \( I^S \).

Proposition 5.19. Let \( I \subseteq P \) be a \( w \)-graded \( \Sigma \)-invariant ideal. If \( G \) is an \( s \)-homogeneous Gröbner basis of \( I^S \) then \( G^P = \pi(G) \) is a Gröbner \( \Sigma \)-basis of \( I \).
the product set denote the free associative algebra generated by commuting variables to the basis \( \sigma \). Since \( G \) is an \( s \)-homogeneous Gröbner basis of \( I^S \), there is \( gsk \in G \) (\( g \in P, k \geq 0 \)) such that \( \text{lm}(f^S) = qsk \cdot \text{lm}(gsk) \cdot s^j \) that is \( \text{lm}(f^S) = qsk \cdot \text{lm}(g) \cdot s^j = q(s^j \cdot \text{lm}(g)) \cdot s^j \) with \( q \in M \) and \( i + j + k = l \). It follows that \( \text{lm}(f) = q(s^j \cdot \text{lm}(g)) = q\text{lm}(s^j \cdot g) \) with \( g = \pi(gsk) \in GP \) and we conclude that \( GP \) is a Gröbner \( \Sigma \)-basis of \( I \). \( \square \)

Note that Proposition 5.18 and Proposition 5.19 explain that there is a complete equivalence between Gröbner bases computations for \( w \)-graded \( \Sigma \)-invariant ideals \( I \subset P \) and their skew analogues \( I^S \) which are graded two-sided ideals of \( S \). In particular, Gröbner \( \Sigma \)-bases of \( I \) can be computed by the algorithm \SigmaGBasis when applied to \( I^S \). Precisely, if \( H = \bigcup_i H_i \) is a \( w \)-homogeneous \( \Sigma \)-basis of \( I \) and \( G = \text{SKewGBasis}(H^S) \) then \( GP = \pi(G) \) is a \( w \)-homogeneous Gröbner \( \Sigma \)-basis of \( I \). We may call this procedure \SigmaGBasis2.

The following result provides algorithmic solution of the membership problem for a class of \( \Sigma \)-invariant ideals. Note that such kind of results are quite rare, for instance, in the theory of difference ideals.

**Proposition 5.20.** Let \( I \subset P \) be a \( w \)-graded \( \Sigma \)-invariant ideal and fix \( d \geq 0 \). Assume that \( I \) has a \( w \)-homogeneous basis \( H \) such that \( H_d = \{ f \in H \mid w(f) \leq d \} \) is a finite set. Then, there is a \( w \)-homogeneous Gröbner \( \Sigma \)-basis \( G \) of \( I \) such that \( G_d \) is also a finite set. In other words, if we consider for the algorithm \SigmaGBasis a selection strategy of the \( S \)-polynomials based on their weights, we obtain that the \( d \)-truncated version of \SigmaGBasis stops in a finite number of steps.

**Proof.** First of all, note that the algorithm \SigmaGBasis essentially computes a subset \( G \) of a Gröbner basis \( \Sigma \cdot G \) obtained by applying the Buchberger algorithm to the basis \( \Sigma \cdot H \) of \( I \). Moreover, by property (iii) of Definition 5.3 and Lemma 5.12 the elements of \( \Sigma \cdot H \) and hence of \( \Sigma \cdot G \) are all \( w \)-homogeneous. Denote \( H'_d = \{ s^i \cdot f \mid i \geq 0, f \in H_d, i + w(f) \leq d \} \). Since \( H'_d \) is also a finite set, consider \( X_d \) the finite set of variables of \( P \) occurring in the elements of \( H'_d \) and define \( P^{(d)} = K[X_d] \). In fact, the \( d \)-truncated algorithm \SigmaGBasis computes a subset of a Gröbner basis of the ideal \( I^{(d)} \) of \( P^{(d)} \) generated by \( H'_d \). By Noetherianity of the ring \( P^{(d)} \), we clearly obtain termination. \( \square \)

Note that the above result can be obtained also by Proposition 4.17. In fact, if \( I \subset P \) is finitely \( \Sigma \)-generated up to weight \( d \) then \( I^S \) is a graded ideal of \( S \) which is finitely generated up to \( s \)-degree \( d \). Precisely, if \( H = \bigcup_i H_i \) is a \( w \)-homogeneous \( \Sigma \)-basis of \( I \) and the set \( \bigcup_{i \leq d} H_i \) is finite for all \( d \), then \( \{ fs^i \mid f \in H_i, i \leq d \} \) is also a finite set that generates \( I^S \) up to degree \( d \).

### 6. The skew letterplace embedding

Denote \( \mathbb{N}^* = \{ 1, 2, \ldots \} \) the set of positive integers and let \( X = \{ x_1, x_2, \ldots \} \) be a finite or countable set of variables. We denote by \( x_i(j) \) each element \( (x_i, j) \) of the product set \( X \times \mathbb{N}^* \) and define \( P = K[X \times \mathbb{N}^*] \) the polynomial ring in the commuting variables \( x_i(j) \). Consider the algebra monomorphism of infinite order \( \sigma : P \to P \) such that \( x_i(j) \mapsto x_i(j + 1) \) for all \( i, j \). Note that \( \sigma \) is a monomial map that is compatible with divisibility in \( \text{Mon}(P) \). Then, put \( S = P[s; \sigma] \) the skew polynomial ring in the variable \( s \) defined by \( P \) and \( \sigma \). Finally, let \( F = K(X) \) denote the free associative algebra generated by \( X \). We consider \( F \) as a graded
algebra with respect to the total degree. Recall that \( S = \bigoplus_{i \in \mathbb{N}} S_i \) is also a graded algebra with \( S_i = Ps^i \).

**Definition 6.1.** Let \( A \subset S \) be a \( K \)-subalgebra. If \( A \) is spanned by a submonoid \( M \subset \text{Mon}(S) \) then we call \( A \) a monomial subalgebra of \( S \) and we denote \( \text{Mon}(A) = M \). In this case, a monomial ordering of \( S \) can be restricted to \( A \).

For instance, \( P \) is a monomial subalgebra of \( S \). We have now a result about the possibility to embed the free associative algebra \( F \) into the skew polynomial ring \( S \).

**Proposition 6.2.** The graded algebra homomorphism \( \iota : F \rightarrow S, x_i \mapsto x_i(1)s \) is injective. Then, the free associative algebra \( F \) is isomorphic to \( R = \text{Im}\iota, \) a graded monomial subalgebra of \( S \).

**Proof.** It is sufficient to note that by the commutation rule of the variable \( s \) and the definition of the endomorphism \( \sigma \), any word \( x_{i_1} \cdots x_{i_d} \in \text{Mon}(F) \) maps into \( x_{i_1}(1) \cdots x_{i_d}(d)s^d \in \text{Mon}(S) \). \( \square \)

We call \( S \) the skew letterplace algebra and the algebra monomorphism \( \iota \) the skew letterplace embedding. In Section 7 we will give motivation for such names. Fix now a monomial ordering \( \prec \) on the algebra \( S \) that is \( \sigma \) is compatible with the restriction of \( \prec \) to \( \text{Mon}(P) \). It is easy to show that many usual monomial orderings on \( P \) (lex, degrevlex, etc) satisfy such condition. Recall that the existence of monomial orderings for \( P \) is provided by the Higman’s lemma which implies the following result (see for instance \([\Pi]\), Corollary 2.3 and remarks at beginning of page 5175).

**Proposition 6.3.** Let \( \prec \) be a total ordering on the set \( \text{Mon}(P) \) such that for all \( m, n, t \in \text{Mon}(P) \) one has \( 1 \leq m \) and if \( m < n \) then \( tm < tn \). Then \( \prec \) is also a well-ordering of \( \text{Mon}(P) \) that is a monomial ordering of \( P \) if and only if the restriction of \( \prec \) to the variables set \( X \times \mathbb{N}^* \) is a well-ordering.

Clearly, it is easy to assign well-orderings to the set \( X \times \mathbb{N}^* \) which is in bijective correspondence to \( \mathbb{N}^2 \). Note that the algebra \( P \) has also a multigrading which is defined as follows. If \( m = x_{i_1}(j_1) \cdots x_{i_d}(j_d) \in \text{Mon}(P) \), then we denote \( \partial(m) = \mu = (\mu_k)_{k \in \mathbb{N}^*} \) where \( \mu_k = \# \{ \alpha \mid j_\alpha = k \} \). If \( P_\mu \subset P \) is the subspace spanned by all monomials of multidegree \( \mu \) then \( P = \bigoplus_\mu P_\mu \) is clearly a multigrading of the algebra \( P \). If \( \mu = (\mu_k) \) is a multidegree, we denote \( i \cdot \mu = (\mu_{k-i})_{k \in \mathbb{N}^*} \) where we put \( \mu_{k-i} = 0 \) when \( k-i < 1 \). By definition of the map \( \sigma \), if we denote \( S_{\mu,i} = P_\mu s^i \) one obtains that \( S = \bigoplus_{\mu,i} S_{\mu,i} \) and \( S_{\mu,i}S_{\nu,j} \subset S_{\mu+i,\nu+j} \). The elements of each subspace \( S_{\mu,i} \subset S \) are said multi-homogeneous. An ideal \( J \subset S \) is called multi-graded if \( J = \sum_{\mu,i} J_{\mu,i} \) with \( J_{\mu,i} = J \cap S_{\mu,i} \). In other words, the ideal \( J \) is generated by multi-homogeneous elements. For any integer \( i \geq 0 \) we denote by \( 1^i \) the multidegree \( \mu = (\mu_k)_{k \in \mathbb{N}^*} \) such that \( \mu_k = 1 \) if \( k \leq i \) and \( \mu_k = 0 \) otherwise. Clearly, a homogeneous element \( fs^i \in S \) \((f \in P)\) belongs to the graded subalgebra \( R \) if and only if \( f \) is multi-homogeneous and \( \partial(f) = 1^i \). In other words, \( R_i = R \cap S_i = S_{1^i,i} = P_1 s^i \).

**Lemma 6.4.** Let \( fs^i \in S \) with \( f \in P \) a multi-homogeneous element and consider \( f_{ij}s^i, g_{js}^j, h_{jk}s^k \in S \) where \( f_{ij}, g_{js}^j, h_{jk}s^k \in P \) are multi-homogeneous elements such that \( fs^i = \sum_{i+j+k=1} f_{ij}s^i g_{js}^j h_{jk}s^k \). Then, from \( fs^i \in R \) it follows that \( f_{ij}s^i, g_{js}^j, h_{jk}s^k \in R_i \) for all \( i, j, k \).
Proposition 6.5. Let \( \rho \) and \( \sigma \) be the definition of the map \( \rho = \partial(h^s_{jk}) \) and \( \sigma = \partial(g^s_{ij}) \) and put \( \alpha = \min\{k \mid \nu_k > 0\} \) and \( \beta = \min\{k \mid \rho_k > 0\} \). By definition of the map \( \sigma \), one has that \( \alpha \geq i + 1 \) and \( \beta \geq i + j + 1 \). If we assume \( fs^l \in R \) that is \( 1^{l} = \partial(f) = \mu + \nu + \rho \), then necessarily \( \mu = 1^{i}, \nu = i \cdot 1^{j} \) and \( \rho = (i + j) \cdot 1^{k} \) and hence \( \partial(f_{ij}) = 1^{i}, \partial(g_{ij}) = 1^{j}, \partial(h_{jk}) = 1^{k} \).

\[ \square \]

Proposition 6.5. Let \( I \) be a graded (two-sided) ideal of \( R \subset S \) and let \( J \) be the extension of \( I \) to \( S \) that is \( J \) is the (multigraded) ideal generated by \( I \) in \( S \). If \( G \) is a multi-homogeneous basis of \( J \) then \( G \cap R \) is a (homogeneous) basis of \( I \). In particular, the contraction \( J \cap R \) is equal to \( I \), that is there is a bijective correspondence between all graded ideals of \( R \) and their extensions to \( S \).

Proof. Consider \( fs^l \in I \subset R (f \in P) \) a homogeneous element and let \( G = \{g_{ij}s^{l}\} \) with \( g_{ij} \in P \), \( g_{ij} \) multi-homogeneous. Since \( f \) is multi-homogeneous and \( G \) is a basis of \( J \subset I \), one has \( fs^l = \sum_{i+j+k+l} f_{ij}s^{l}g_{ij}s^{l}h_{jk}s^{k} \) with \( f_{ij}, h_{jk} \in P \), \( f_{ij}, h_{jk} \) multi-homogeneous. From Lemma 6.4 it follows immediately that all elements \( f_{ij}s^{l}, g_{ij}s^{l}, h_{jk}s^{k} \in R \) that is \( G \cap R \) is a basis of \( I \).

\[ \square \]

Proposition 6.6. Let \( I \subset R \) be a graded ideal and let \( J \subset S \) be its extension. If \( G \subset J \) is a multi-homogeneous Gröbner basis of \( J \) then \( G \cap R \) is a homogeneous Gröbner basis of \( I \).

Proof. If \( fs^l = \sum_{i+j+k+l} f_{ij}s^{l}g_{ij}s^{l}h_{jk}s^{k} \) is a Gröbner representation in \( S \) of a homogeneous element \( fs^l \in I \subset J \) with respect to \( G = \{g_{ij}s^{l}\} \), then it is sufficient to use the same argument of Proposition 6.5 to obtain that \( fs^l \) has a Gröbner representation in \( R \) with respect to \( G \cap R \).

\[ \square \]

We obtain finally an algorithm to compute Gröbner bases of graded two-sided ideals of the subring \( R \subset S \) which is isomorphic to the free associative algebra \( F \) by the map \( \iota \). Note that the considered monomial orderings on \( F \) are obtained as the restriction of monomial orderings on \( S \) to the monomial subalgebra \( R \). By applying Proposition 6.6, the computation of homogeneous Gröbner bases in \( R \) is obtained as a slight modification of the algorithm \text{SKWGBASIS} for the ideals of \( S \). It is interesting to note that the latter procedure is in turn a variant of the Buchberger algorithm for modules over commutative polynomial rings. Thus, we may say that these computations in associative algebras are reduced to analogue ones over commutative rings via the notion of skew polynomial ring (see also Section 7). This reverses somehow the trivial fact that commutative algebras are just a subclass of the associative ones.
Algorithm 6.1 FreeGBasis2

Input: $H$, a homogeneous basis of a graded two-sided ideal $I \subset R$.
Output: $G$, a homogeneous Gröbner basis of $I$.

$G := H$;
$B := \{(f, g) \mid f, g \in G\}$;

while $B \neq \emptyset$ do
  choose $(f, g) \in B$;
  $B := B \setminus \{(f, g)\}$;
  for all $i, j \geq 0, i + j = \deg_s(f) - \deg_s(g)$ and $\text{spoly}(f, s^i g s^j) \in R$ do
    $h := \text{Reduce}(\text{spoly}(f, s^i g s^j), \Sigma G \Sigma)$;
    if $h \neq 0$ then
      $B := B \cup \{(h, h), (h, k), (k, h) \mid k \in G\}$;
      $G := G \cup \{h\}$;
    end if;
  end for;
  for all $i, j \geq 0, j - i = \deg_s(f) - \deg_s(g)$ and $\text{spoly}(f s^i, s^j g) \in R$ do
    $h := \text{Reduce}(\text{spoly}(f s^i, s^j g), \Sigma G \Sigma)$;
    if $h \neq 0$ then
      $B := B \cup \{(h, h), (h, k), (k, h) \mid k \in G\}$;
      $G := G \cup \{h\}$;
    end if;
  end for;
end while;
return $G$.

Note explicitly that conditions $\text{spoly}(f, s^i g s^j), \text{spoly}(f s^i, s^j g) \in R$ are equivalent to ask that such multi-homogeneous elements of $S$ have multidegrees of type $(1^d, d)$, for some $d \geq 0$.

Proposition 6.7. The algorithm FreeGBasis2 is correct.

Proof. Since $G$ is multi-homogeneous implies that $\Sigma G \Sigma$ is also multi-homogeneous, the procedure $\text{Reduce}$ clearly preserves multi-homogeneity. Moreover, any element $f \in G$ ($f \notin H$) is obtained by reduction of a $S$-polynomial, say $h$. Owing to Proposition 6.6 we are interested only in the elements $f \in R$ and this holds if and only if $h \in R$. □

Assume now that the graded ideal $I \subset R$ has a finite number of generators up to some degree $d > 0$. Note that the $d$-truncated algorithm FreeGBasis2 has termination provided by termination of SkewGBasis as stated in Proposition 4.7. This generalizes a well-known result about algorithmic solution of the word problem (membership problem) for finitely presented graded associative algebras.

7. Letterplace in $P$

As in Section 5, consider the $P$-linear map $\pi : S \to P$ such that $s^i \mapsto 1$, for all $i$. Note now that $\iota' = \pi \iota : F \to P$ is an injective $K$-linear map such that $x_{i_1} \cdots x_{i_d} \in \text{Mon}(F) \mapsto x_{i_1}(1) \cdots x_{i_d}(d) \in \text{Mon}(P)$. Recall that $F = \bigoplus F_i$ is a graded algebra with respect to total degree. Moreover, consider the weight map $w : \text{Mon}(P) \to \mathbb{N}$ such that $w(x_{i}(j)) = j$ for all $i, j \geq 1$ and the corresponding
Proposition 7.2. Let \( w \in \mathbb{F} \). Define by \( \mathcal{I} \) the \( \mathbb{F} \)-homogeneous map (note \( K = F_0 = P_{-\infty} \) and \( P_0 = 0 \) and \( \iota = \xi \iota' \) which is an algebra homomorphism.

Definition 7.1. Let \( I \subseteq \mathbb{F} \) a be graded (two-sided) ideal. Denote by \( I' \subseteq P \) the \( \mathbb{F} \)-graded \( \Sigma \)-invariant ideal \( \Sigma \)-generated by \( \iota'(I) \). In other words, if \( G = \{ \iota'(f) \mid f \in I_i, i > 0 \} \) then \( I' \) is the ideal of \( P \) generated by \( \Sigma \cdot G \). We call \( I' \) the letterplace analogue of \( I \).

Proposition 7.2. Let \( I \subseteq \mathbb{F} \) a be graded ideal and \( I' \subseteq P \) its letterplace analogue. Denote by \( J = I'^S \) the skew analogue of \( I' \) and call \( J \) the skew letterplace analogue of \( I \). We have that \( J \) is the extension to \( \mathbb{F} \) of the ideal \( \iota(I) \subset R \). Then, there is a bijective correspondence between all graded ideals of \( F \) and their (skew) letterplace analogues.

Proof. Let \( J' \) be the extension of \( \iota(I) \) to \( \mathbb{F} \). By definition \( J' \) is the ideal generated by the elements \( \iota(f) = \iota'(f) s^i \), for all \( f \in I_i \). Since \( J' \) is \( \Sigma \)-generated by the \( \mathbb{F} \)-homogeneous elements \( \iota'(f) \) of weight \( i \), we conclude that \( J = I'^S = J' \).

Moreover, the bijective correspondence between graded two-sided ideals of \( \mathbb{F} \) and their letterplace analogues is obtained by composing the bijections contained in Proposition 5.12 and Proposition 6.5.

The bijection between graded ideals of \( \mathbb{F} \) and their letterplace analogues has been introduced in [22] and called “letterplace correspondence”. The motivation of such name is essentially historical since the linear map \( \iota' \) was first considered in [11, 7]. Note that in these articles the endomorphism \( \sigma \) and the algebra embedding \( \iota \) were not introduced. The polynomial ring \( \mathbb{F} \) was named there the “letterplace algebra” because in the monomial \( \iota'(x_{i_1} \cdots x_{i_d}) = x_{i_1}(1) \cdots x_{i_d}(d) \) the indices \( 1, \ldots, d \) play the role of the “places” where the “letters” \( x_{i_1}, \ldots, x_{i_d} \) occur in the word \( x_{i_1} \cdots x_{i_d} \in \text{Mon}(\mathbb{F}) \).

Fix now a monomial ordering \( \prec \) on the algebra \( \mathbb{F} \) that is \( \sigma \) is compatible with the restriction of \( \prec \) to \( \text{Mon}(\mathbb{F}) \). By restricting \( \prec \) to \( R \) one obtains a monomial ordering on \( \mathbb{F} \). Denote by \( V \) the image of the map \( \iota' \) that is \( V = \bigoplus_i V_i \) is a graded subspace of \( \mathbb{F} \) where \( V_i = P_{i_1} \subset P_{i_1} \). Note that \( V \) is a left \( R \)-module isomorphic to \( R \approx \mathbb{F} \). In fact, \( V = \pi(R) \) and the restriction \( \pi : R \to V \) has the restriction \( \xi : V \to R \) as its inverse. In [22] one has the following result which is now a direct consequence of Proposition 5.18 and Proposition 6.6.

Proposition 7.3. Let \( I \subseteq \mathbb{F} \) be a graded ideal and denote by \( J \subseteq P \) its letterplace analogue. Then \( J \) is a multigraded (hence \( \mathbb{F} \)-graded) \( \Sigma \)-invariant ideal of \( P \). If \( G \) is a multi-homogeneous (hence \( \mathbb{F} \)-homogeneous) Gröbner \( \Sigma \)-basis of \( I \) then \( \iota^{-1}(G \cap V) \) is a homogeneous Gröbner basis of \( I \).

From this result and algorithm \text{SIGMA} \text{GB} \text{AS} \text{IS} one obtains the correctness of the following procedure which also has been introduced in [22].
Algorithm 7.1 FreeGBasis

Input: $H$, a homogeneous basis of a graded two-sided ideal $I \subseteq F$.
Output: $\iota^{-1}(G)$, a homogeneous Gröbner basis of $I$.

$G := \iota(H)$;
$B := \{(f, g) \mid f, g \in G\}$;

while $B \neq \emptyset$ do
  choose $(f, g) \in B$;
  $B := B \setminus \{(f, g)\}$;
  for all $i \geq 0$ such that $\text{spoly}(f, s^i \cdot g) \in V$ do
    $h := \text{Reduce}(\text{spoly}(f, s^i \cdot g), \Sigma \cdot G)$;
    if $h \neq 0$ then
      $B := B \cup \{(h, h), (h, k), (k, h) \mid k \in G\}$;
      $G := G \cup \{h\}$;
    end if;
  end for;
end while;
return $\iota^{-1}(G)$.

Assume finally that the graded ideal $I \subseteq F$ has a finite number of generators up to some degree $d > 0$. Note that the $d$-truncated algorithm FreeGBasis has now termination provided by Proposition 5.20.

8. Examples and timings

In this section we propose an explicit computation and some timings in order to provide some concrete experience with the algorithms we introduced.

Let $X = \{x\}$ and consider the ring of ordinary difference polynomials $P = K[X \times \mathbb{N}]$ that is $P$ is the polynomial ring in the variables $x(j)$ which are the shifts of a single univariate function $x = x(0)$. Moreover, let $P$ be endowed with the lexicographic monomial ordering where $x(0) < x(1) < \ldots$. Denote by $J$ the difference ideal generated by the single difference polynomial $g_1 = x(2)x(0) - x(1)$. This ideal has been considered in [18] as an example of an ordinary difference equation with periodic solutions. A variant of this equation has also been considered in [12]. By the algorithm SigmaGBasis one can compute that $J$ has a finite Gröbner difference basis with elements

$g_1 = x(2)x(0) - x(1),
g_2 = x(4)x(1) - x(3)x(0),
g_3 = x(3)^2x(0) - x(3),
g_4 = x(4)x(3)x(0) - x(4),
g_5 = x(5) - x(4)x(0)$.

Let us see how the algorithm SigmaGBasis is able to obtain this. If $\Sigma = \langle \sigma \rangle$ where $\sigma : P \rightarrow P$ is the shift endomorphism $x(i) \mapsto x(i + 1)$, then the ideal $J$ is by definition $\Sigma$-generated by $\{g_1\}$ that is it is generated by $\Sigma \cdot \{g_1\} = \{x(2)x(0) - x(1), x(3)x(1) - x(2), x(4)x(2) - x(3), \ldots\}$. Up to the product criterion, to compute a Gröbner basis of $J$ one should consider all the S-polynomials $\text{spoly}(\sigma^i g_1, \sigma^{i+2} \cdot g_1)$ for any $i \geq 0$. We are interested in fact in computing a Gröbner $\Sigma$-basis of $J$ and hence we can apply the $\Sigma$-criterion that kills all these S-polynomials except for $\text{spoly}(g_1, \sigma^2 \cdot g_1)$. The reduction of this element with respect to $\Sigma \cdot \{g_1\}$ leads
to \( g_2 = x(4)x(1) - x(3)x(0) \). Now the current \( \Sigma \)-basis of \( J \) is \( \{g_1, g_2\} \). The \( S \)-
polynomials that survive to product and \( \Sigma \)-criterion are now

\[
\text{spoly}(g_2, \sigma \cdot g_1), \text{spoly}(g_2, \sigma^2 \cdot g_1), \text{spoly}(g_2, \sigma^3 \cdot g_1), \text{spoly}(g_1, \sigma \cdot g_2), \\
\text{spoly}(g_2, \sigma^3 \cdot g_2).
\]

Then \( \text{spoly}(g_2, \sigma^2 \cdot g_1) \rightarrow 0 \) and \( \text{spoly}(g_2, \sigma \cdot g_1) \) reduces to \( g_3 \) with respect to \( \Sigma \cdot \{g_1, g_2\} \). The list of new \( S \)-polynomials arising from \( g_3 \) that pass product and \( \Sigma \)-criterion is

\[
\text{spoly}(g_3, g_1), \text{spoly}(g_3, \sigma \cdot g_1), \text{spoly}(g_3, \sigma^2 \cdot g_1), \text{spoly}(g_3, \sigma^3 \cdot g_1), \\
\text{spoly}(g_2, \sigma \cdot g_3), \text{spoly}(g_3, \sigma^2 \cdot g_3), \text{spoly}(g_3, \sigma^3 \cdot g_3), \text{spoly}(g_2, \sigma^4 \cdot g_3).
\]

We have now that \( \text{spoly}(g_3, \sigma \cdot g_1) \rightarrow 0, \text{spoly}(g_3, g_1) \rightarrow 0 \) and \( \text{spoly}(g_2, \sigma \cdot g_3) \rightarrow g_4. \)

Up to all criteria, including chain criterion, the list of \( S \)-polynomials has to be updated with the following ones

\[
\text{spoly}(g_4, \sigma \cdot g_1), \text{spoly}(g_4, \sigma^2 \cdot g_1), \text{spoly}(g_4, \sigma^3 \cdot g_1), \text{spoly}(g_4, \sigma^4 \cdot g_1), \\
\text{spoly}(g_4, \sigma^3 \cdot g_2), \text{spoly}(g_4, \sigma \cdot g_4), \text{spoly}(g_4, \sigma^2 \cdot g_4), \text{spoly}(g_4, \sigma^3 \cdot g_4), \\
\text{spoly}(g_4, \sigma^2 \cdot g_4), \text{spoly}(g_4, \sigma \cdot g_2), \text{spoly}(g_4, \sigma^3 \cdot g_2), \text{spoly}(g_4, \sigma^4 \cdot g_2).
\]

Now, one has the following reductions: \( \text{spoly}(g_4, \sigma \cdot g_1) \rightarrow 0, \text{spoly}(g_4, \sigma^2 \cdot g_1) \rightarrow 0 \) and \( \text{spoly}(g_1, \sigma \cdot g_2) \rightarrow f = x(5)x(1) - x(3)x(0)^2 \). We will show that the element \( f \) of the \( \text{Gröbner} \) \( \Sigma \)-basis of \( J \) is in fact redundant because \( g_5 \) is also in this basis. The new \( S \)-polynomials arising from \( f \) are

\[
\text{spoly}(f, \sigma \cdot g_1), \text{spoly}(f, \sigma^2 \cdot g_1), \text{spoly}(f, \sigma \cdot g_2), \text{spoly}(f, \sigma^2 \cdot g_2), \\
\text{spoly}(g_1, \sigma \cdot f), \text{spoly}(g_2, \sigma^2 \cdot f), \text{spoly}(g_3, \sigma^2 \cdot f), \text{spoly}(g_4, \sigma \cdot f), \\
\text{spoly}(g_4, \sigma^3 \cdot f), \text{spoly}(g_4, \sigma^4 \cdot f).
\]

Then, we start again with reductions: \( \text{spoly}(f, \sigma \cdot g_2) \rightarrow 0, \text{spoly}(f, \sigma \cdot g_1) \rightarrow 0, \)

\( \text{spoly}(g_3, \sigma^3 \cdot g_1) \rightarrow 0, \text{spoly}(g_2, \sigma \cdot g_4) \rightarrow g_5 \) and therefore \( f \) is redundant. The last \( S \)-polynomials to be added are

\[
\text{spoly}(g_5, \sigma^3 \cdot g_1), \text{spoly}(g_5, \sigma^3 \cdot g_1), \text{spoly}(g_5, \sigma \cdot g_2), \text{spoly}(g_5, \sigma^4 \cdot g_2), \\
\text{spoly}(g_5, f), \text{spoly}(g_5, \sigma^3 \cdot f).
\]

If \( G = \{g_1, g_2, g_3, g_4, g_5\} \) then we have that all remaining \( S \)-polynomials to be
considered reduce to zero with respect to \( \Sigma \cdot G \), that is \( G \) is a \( \text{Gröbner} \) \( \Sigma \)-basis (difference basis) of the \( \Sigma \)-ideal (difference ideal) \( J \).

We present now some timings obtained with an implementation of the algorithm \textsc{FreeGBasis}. This implementation, which is still under development, is an improvement of the one we presented in \cite{22}. We decided not to start implementing also \textsc{FreeGBasis2} until \textsc{FreeGBasis} will evolve to some final form. We propose here new comparisons with the system \textsc{Magma} that contains one of the most effective implementations of the classical algorithm \cite{27, 15, 29} for computing non-commutative \( \text{Gröbner} \) bases. Note that this implementation takes also advantage by the use of Faugère’s F4 approach. The tests were performed on a PC with four Intel Core i7 CPU 940 2.93GHz processors with 12 GB RAM running Ubuntu Linux. We used \textsc{Singular} 3-1-3 with \textsc{freegb.lib} release 14203 and \textsc{Magma} version 2.17-8.

We measured the time for real execution of the process (thus differently to the way we did comparisons in \cite{22}) in “min:sec” format. The number of generators in the input and in the output are given as well.
This table shows essentially that the letterplace approach to the computation of non-commutative Gröbner bases is comparable with the classical algorithms and hence it is feasible. From the viewpoint of implementations we record that MAGMA achieved significant improvements with respect to comparisons included in [22] and this stimulate us to further optimize our code. In fact, there is an ongoing work to enhance freegb.lib in SINGULAR. We will make more extensive comparisons in future articles that will be concentrated on technical aspects of implementing the letterplace algorithms.

Here is a brief description of the examples we considered for testing. In all the examples the last integer indicates the total degree that bounds the computations. The examples G3-5-6-2, G2-3-13-4 refer to the class of presented groups $G(l, m, n; q) = \langle r, s | r^n, s^m, (rs)^q, [r, s]^q \rangle$, where $[r, s]$ denotes the commutator. As for the example G3-8-13, this one is from the class of groups $G(m, n, p) = \langle a, b, c | a^m, b^n, c^p, (ab)^2, (bc)^2, (ca)^2, (abc)^2 \rangle$. All these groups has been considered by Coxeter [4] for the problem of determining their finiteness. For our computations we considered a homogenization of the ideal of the free associative algebra defining the group algebra of such groups. The example serf-g2 are modified full Serre relations built from the Cartan matrix $G_2$. The following non-commutative polynomials are explicitly the generators we considered for homogenization:

$$
\begin{align*}
&f_1 f_2 f_3 - 2 f_3 f_1 f_2 + f_3 f_2 f_1 + e_1 e_2 e_2 - 2 e_2 e_1 e_2 + e_2 e_2 e_1, \\
&f_1 f_2 f_1 f_2 - 4 f_1 f_2 f_1 f_1 + 6 f_1 f_1 f_2 f_1 - 4 f_1 f_2 f_1 f_1 + f_2 f_1 f_1 f_1, \\
&e_1 e_1 e_2 e_2 - 4 e_1 e_1 e_2 e_1 + 6 e_1 e_1 e_2 e_1 - 4 e_1 e_1 e_2 e_1 + e_2 e_1 e_2 e_1,
\end{align*}
$$

For the example cliff5d9 refer to the class of presented groups $(4, 1)$ (see [20]) and includes also variations of those. For instance, cliff5d9 is given by

$$
\begin{align*}
&f_5 = K\langle x_1, x_2, x_3, x_4, x_5 \rangle \text{ and define } \Gamma \subseteq \text{End}_K(F_5) \text{ the submonoid of all algebra endomorphisms sending variables into variables. The example cliff5 is the ideal } I \subseteq F_5 \text{ which is } \Gamma\text{-generated by the polynomials } [x_1 \circ x_2, x_3] = (x_1 x_2 + x_2 x_1) x_3 - x_3 (x_1 x_2 + x_2 x_1) \text{ and } s_5 = \sum_{\pi \in S_5} \text{sgn}(\pi)x_{\pi(1)}x_{\pi(2)}x_{\pi(3)}x_{\pi(4)}x_{\pi(5)}. 
\end{align*}
$$

The quotient ring $F_5/I$ is the generic Clifford algebra in 5 variables of a 4-dimensional vector space. Finally, the family C41 of examples originates from random linear substitutions into the ideal of 6 generators, defining the non-cancellative monoid $C(4, 1)$ (see [20]) and includes also variations of those. For instance, C41W is given by

$$
\begin{align*}
&f_5 = K\langle x_1, x_2, x_3, x_4, x_5 \rangle \text{ and define } \Gamma \subseteq \text{End}_K(F_5) \text{ the submonoid of all algebra endomorphisms sending variables into variables. The example cliff5 is the ideal } I \subseteq F_5 \text{ which is } \Gamma\text{-generated by the polynomials } [x_1 \circ x_2, x_3] = (x_1 x_2 + x_2 x_1) x_3 - x_3 (x_1 x_2 + x_2 x_1) \text{ and } s_5 = \sum_{\pi \in S_5} \text{sgn}(\pi)x_{\pi(1)}x_{\pi(2)}x_{\pi(3)}x_{\pi(4)}x_{\pi(5)}. 
\end{align*}
$$
by
\[
\begin{align*}
x_4 x_4 - 25x_4 x_2 - x_1 x_4 - 6x_1 x_3 - 9x_1 x_2 + x_1 x_1, \\
x_4 x_3 + 13x_4 x_2 + 12x_4 x_1 - 9x_3 x_4 + 4x_3 x_2 + 41x_3 x_1 - 7x_1 x_4 - x_1 x_2, \\
x_4 x_3 - 9x_3 x_2 + 2x_1 x_4 + x_1 x_1, 17x_4 x_2 - 5x_2 x_2 - 41x_1 x_4, \\
x_2 x_2 - 13x_2 x_1 - 4x_1 x_3 + 2x_1 x_2 - x_1 x_1, x_2 x_1 + 4x_1 x_2 - 3x_1 x_1.
\end{align*}
\]

while \(C41\) is given by
\[
\begin{align*}
189x_4 x_4 + 63x_4 x_3 - 66x_4 x_2 - 161x_4 x_1 - 103x_3 x_4 + 19x_3 x_3 + 262x_3 x_2 + 467x_3 x_1 - \\
300x_2 x_4 - 144x_2 x_3 + 24x_2 x_2 + 136x_2 x_1 + 175x_1 x_4 + 35x_1 x_3 - 160x_1 x_2 - 315x_1 x_1, \\
27x_4 x_4 + 409x_4 x_3 + 82x_4 x_2 - 42x_4 x_1 - 57x_3 x_4 - 403x_3 x_3 + 26x_3 x_2 - 42x_3 x_1 - \\
50x_2 x_4 - 434x_2 x_3 - 12x_2 x_2 - 14x_2 x_1 + 45x_1 x_4 + 435x_1 x_3 + 30x_1 x_2, \\
232x_4 x_4 - 29x_4 x_3 + 77x_4 x_2 + 332x_4 x_1 - 147x_3 x_4 + 175x_3 x_3 + 60x_3 x_2 - 269x_3 x_1 - \\
107x_2 x_4 + 184x_2 x_3 + 83x_2 x_2 - 217x_2 x_1 + 28s_1 x_4 - 217x_1 x_3 - 139x_1 x_2 + 120x_1 x_1, \\
52x_1 x_4 + 233x_1 x_3 - 129x_1 x_2 + 155x_1 x_1 - 248x_3 x_4 - 205x_3 x_3 + 171x_3 x_2 + 138x_3 x_1 + \\
100x_2 x_4 - 58x_2 x_3 - 177x_2 x_2 + 84x_2 x_1 + 39x_1 x_4 - 43x_1 x_3 - 73x_1 x_2 - \\
225x_4 x_4 - 150x_4 x_3 - 179x_4 x_2 - 262x_4 x_1 + 91x_3 x_4 - 94x_3 x_3 + 225x_3 x_2 + 74x_3 x_1 + \\
214x_2 x_4 + 224x_2 x_3 + 90x_2 x_2 + 266x_2 x_1 - 175x_1 x_4 - 50x_1 x_3 - 205x_1 x_2 - 190x_1 x_1, \\
289x_4 x_4 - 170x_4 x_3 - 289x_4 x_2 - 153x_4 x_1 - 186x_3 x_4 + 95x_3 x_3 + 177x_3 x_2 + 106x_3 x_1 - \\
231x_2 x_4 + 35x_2 x_3 + 168x_2 x_2 + 175x_2 x_1 + 241x_1 x_4 + 60x_1 x_3 - 115x_1 x_2 - 233x_1 x_1.
\end{align*}
\]

9. CONCLUSIONS AND FUTURE DIRECTIONS

From the previous sections we can conclude that, owing to the notion of Gröbner \(\Sigma\)-basis and the skew letterplace embedding \(i\), the theory of non-commutative Gröbner bases developed for the free associative algebra \(F = K\langle X \rangle\) using the concepts of overlappings, tips or obstructions \([15, 27, 29]\) can be deduced from, unified to the classical Buchberger theory for commutative polynomial rings based on \(S\)-polynomials, at least in the graded case. From a practical point of view, one obtains the alternative algorithms \textsc{FreeGBasis} and \textsc{FreeGBasis2} which are implementable in any computer algebra system providing commutative Gröbner bases. The feasibility of such methods has been already shown in \([22]\) and confirmed by the new timings we have collected in Section 8.

Moreover, the general theory developed in this paper can be applied to any context where a monoid of endomorphisms \(\Sigma\) acts on the polynomial algebra \(P = K[X]\) in a way which is compatible with Gröbner bases theory. We propose not only an abstract definition of what this may mean contributing to a current research trend (see for instance \([9, 11, 13]\)), but also a method to transfer the related algorithms from \(P\) to the skew monoid ring \(S = P \ast \Sigma\) when a suitable grading is given for \(P\). This theory applies in particular to the shift operators and hence a stimulating \(\langle\text{Gröbner }\Sigma\text{-bases theory}\rangle\) to any finitely generated free commutative monoid \(\Sigma = \langle \sigma_1, \ldots, \sigma_r \rangle\) in order to cover partial difference ideals and to extend the letterplace method for \(F\) to the non-graded case by means of suitable (de)homogenization techniques. An effective implementation of all proposed algorithms will be clearly important to understand the actual performance of the methods.

ACKNOWLEDGMENTS

First of all, we would like to thank Vladimir Gerdt for introducing us to the theory of difference polynomial rings and thus leading us to note that the letterplace algebra \(K[X \times \mathbb{N}]\) endowed with the endomorphism \(x_i(j) \mapsto x_i(j + 1)\) is just an
instance of them (ordinary case). We are grateful to Albert Heinle, Benjamin Schnitzler and Grischa Studzinski for adopting the SYMBOLICDATA project [28] for handling ideals in free algebras. The timings in this article were obtained with the help of the updated SYMBOLICDATA system. We like also to thank the anonymous reviewers for their valuable comments and suggestions.
