(Received 19 July 2016, accepted 19 October 2016; J-STAGE Advance published date: 21 December 2016)

Hair cells in the cochlea display highly regulated actin polymerization, which is mediated by the human diaphanous-related formin 1 gene (\textit{DIAPH1}; also called \textit{DFNA1}, \textit{DIA1}). \textit{DFNA1}, the first type of autosomal dominant nonsyndromic hearing loss (ADNSHL), is known to be associated with mutations in \textit{DIAPH1}. However, no genetic study of \textit{DFNA1} in Koreans with hearing loss has yet been reported. A 51-year-old patient in a Korean family with ADNSHL was examined by pure-tone audiometry, and genetic analysis of \textit{DIAPH1} was performed. A novel variant, p.I530S (c.1589T > G), was identified in the \textit{DIAPH1} gene, and the mutation was located in the highly conserved coiled-coil domain of the DIA1 protein, where an amino acid substitution was predicted to change the domain structure. Further functional investigations will provide more information to help us understand the role of \textit{DIAPH1} in maintenance of hair cell function in the auditory pathway.

Key words: \textit{DIAPH1}, diaphanous-related formin 1, DFNA1, autosomal dominant nonsyndromic hearing loss in Koreans

Hair cells in the inner ear are mechanoreceptors that mediate mechanoelectrical transduction in the auditory pathway (Frolenkov et al., 2004). Stereocilia, which are apical modifications of the hair cells in the cochlea, are the key organelles that convert the mechanical stimulation of sound waves into electrical signals in the hair cells (Hudspeth and Corey, 1977). The stereocilium is composed of actin filaments that are tightly regulated by polymerization and depolymerization to maintain the structure of stereocilia (Tilney et al., 1983; Breneman et al., 2009). Actin polymerization is mediated by the direct interaction between formin proteins and profilin–actin complexes (Tilney et al., 1983; Nouvian et al., 2006; Breneman et al., 2009). Formins recruit these complexes to the barbed ends of the growing actin filaments, leading to the assembly of new actin polymers (Krebs et al., 2001; Evangelista et al., 2003; Suarez et al., 2015). Actin polymerization is involved in various central cellular processes such as differentiation, migration, adhesion, signaling and gene expression, as well as structural maintenance (Mattila and Lappalainen, 2008).

The diaphanous-related formins (DRFs), members of the formin family, directly promote actin filament growth (Wallar and Alberts, 2003). The human diaphanous-related formin 1 (DIA1) protein is encoded by the \textit{DIAPH1} gene (Lynch et al., 1997). \textit{DIAPH1} is located on chromosome 5q31 and consists of 28 exons, and is known to be associated with autosomal dominant nonsyndromic hearing loss (ADNSHL) (Lynch et al., 1997). To date, only a small number of mutations in this gene have been reported as the cause of ADNSHL, including the Costa Rican kindred with low-frequency progressive hearing loss.
loss (Lynch et al., 1997; Baek et al., 2012). In this study, we report a novel missense variant in the DIAPH1 gene in a Korean patient with ADNSHL.

A 51-year-old male with sensorineural hearing loss (HL) presented to our hospital. He had been diagnosed with HL a decade previously. This patient (III-1) had a family history of HL (Fig. 1A), the heredity pattern of which was autosomal dominant. The threshold hearing levels of the patient were examined by pure-tone audiometry in a sound-proof room, at sound frequencies of 250, 500, 1,000, 2,000, 4,000 and 8,000 Hz. The level of HL was based on the standards of a previous study (Sagong et al., 2016). The pure-tone audiogram of the patient revealed a steeply sloping form (Fig. 1B).

For genetic analysis, 100 unrelated individuals with normal hearing were recruited from Kyungpook National University as control subjects. The participants provided written informed consent before the study according to the protocol approved by the Ethics Committee of Kyungpook National University Hospital. Genomic DNA from blood samples of the patient and control individuals was extracted using the FlexiGene DNA Extraction Kit (Qiagen, Hilden, Germany). Primers were designed using 3web (http://primer3.ut.ee) to amplify each coding region containing flanking splice junctions of DIAPH1 (Supplementary Table S1). Amplification of each exon was carried out by PCR using h-Taq DNA polymerase (Solgent, Daejeon, Korea), and the PCR products were confirmed on a 1.5% agarose gel by electrophoresis. Exonuclease I (USB, Cleveland, OH, USA) and shrimp alkaline phosphatase (USB) were used to purify the PCR products, and their sequences were determined by thermal cycling PCR using the BigDye Terminator v3.1 Cycle Sequencing Kit (Applied Biosystems, Foster City, CA, USA). Sanger

A novel DIAPH1 gene variant in Koreans

sequence was carried out by capillary electrophoresis on a 3130xl Genetic Analyzer (Applied Biosystems). For sequence data analysis, Sequencing Analysis v5.2 (Applied Biosystems), SeqScape v2.5 (Applied Biosystems) and ChromasPro v1.7 (Technelysium, Tewantin, QLD, Australia) were used. Finally, the sequence of each exon was compared with that of the reference DIAPH1 (NG_011594.1, NM_005219.4) sequence registered in the NCBI (http://www.ncbi.nlm.nih.gov/) database. To investigate the probable pathogenicity and novelty of detected variants, several different exome databases were used as references: the 1000 Genomes Project Browser (http://www.1000genomes.org/), dbSNP (http://www.ncbi.nlm.nih.gov/snp/), the Human Genetic Variation database (http://www.genome.med.kyoto-u.ac.jp/), the NHLBI GO Exome Sequencing Project (http://evs.gs.washington.edu/ EVS/) and the Exome Aggregation Consortium (ExAC) browser (http://exac.broadinstitute.org/). Conservation of the DIAP1 protein sequence among species was compared using CLC Sequence Viewer v6.0 (CLC Bio, Aarhus, Denmark), and the change of structural stability caused by mutations was predicted using MUpro, a web-based program to predict the change of structural stability caused by mutations was predicted using MUpro to decrease the structural stability of the protein, with a highly significant confidence score of −1, suggesting that the p.I530S mutation would destabilize the coiled-coil (CC) domain in the DIA1 protein. Moreover, this variant was located in a region of DIA1 that is highly conserved among various mammalian species (Fig. 1D), suggesting that this region, including isoleucine 530, is important for protein function. The PCR products amplified from the 100 normal controls were not digested by Sse9I, indicating that these unrelated individuals did not harbor the p.I530S variant (Fig. 1E).

DIAPH1 was reported as the first causative gene of ADNSHL in a large Costa Rican kindred in 1997 (Lynch et al., 1997), but since then no further genetic studies of DIAPH1-related ADNSHL have been published. However, we recently reported a novel and probably pathogenic mutation in DIAPH1 in a patient with ADNSHL, identified by targeted massively parallel sequencing (Baek et al., 2012), which suggested the desirability of investigating the prevalence of DIAPH1-related ADNSHL in the Korean population. In this study, we have now found another novel missense variant in a different patient, suggesting the possibility that DIAPH1 is not a minor causative gene of hearing loss in Koreans. Further genetic analysis of DIAPH1 in a larger patient population will provide useful genetic information about Korean hereditary hearing loss.

Although DIA1-regulated actin polymerization is essential for cell activity (Mattila and Lappalainen, 2008), the pathogenic effect of DIA1 malfunction caused by structural change is not well known in hair cells. The DIA1 protein contains CC, Rho-GTPase binding, diaphanous inhibited, formin homology (FH)1, FH2, FH3, and diaphanous autoinhibitory domains (Zigmond, 2004; Higgs, 2005). FH domains play an important role in actin polymerization by interacting with profilin–actin complexes (Wallar and Alberts, 2004; Parry et al., 2008). Hydrophobic nonpolar residues such as leucine, isoleucine and valine are key to maintaining the stable helical structure of CCs (Harbury et al., 1993; Parry et al., 2008). This indicates that chemical features of individual amino acids in the CCs can affect or even determine structural stabilization or functions of the protein. The p.I530S variant found in this study is located in a repeated region of nonpolar residues in the CC domain (Fig. 2). Therefore, the change of nonpolar isoleucine to polar serine in this region might have the potential to affect the original repeating pattern of nonpolar residues, leading to structural alteration of the protein. Since the cells in the inner ear are highly sensitive to actin fibers and actin filament networks, func-
tional loss of actin regulators such as DIA1 may lead to failure in maintaining the normal morphology and functions of the cells (Tilney et al., 1980). In conclusion, we report a genetic analysis of the DIAPH1 gene in a Korean family with ADNSHL. Further functional investigations should provide stronger evidence to test our hypothesis that the p.I530S variant has the potential to disrupt the maintenance of normal DIA1 structure and functions.
