Abstract

Several years ago the second author playing with different “recognizers of real constants”, e.g., the LLL algorithm, the Plouffe inverter, etc. found the following formula empirically. Let $p_n/q_n$ denote the $n$th convergent of the continued fraction of the constant $e$. Then

$$\sum_{n \geq 0} |q_n e - p_n| = \frac{e}{4} \left( -1 + 10 \sum_{n \geq 0} \frac{(-1)^n}{(n+1)! (2n^2 + 7n + 3)} \right).$$

The purpose of the present paper is to prove this formula and to give similar formulas for some powers of $e$.

**Keywords:** Continued fractions; convergents; approximation of real numbers; Hurwitzian continued fractions; error sum function.

**MSC Classes:** 11A55, 11J70, 11B83, 11B75.

*The author was partially supported by the ANR project “FAN” (Fractals et Numération), ANR-12-IS01-0002.
1 Introduction

Playing with the convergents of $e$, the second author discovered several years ago the formula

$$
\sum_{n \geq 0} |q_n e - p_n| = \frac{e}{4} \left( -1 + 10 \sum_{n \geq 0} \frac{(-1)^n}{(n+1)!(2n^2 + 7n + 3)} \right).
$$

(1)

While trying to prove the formula rigorously we began being interested in the following quantity. If $\alpha$ is a positive real number, and if $p_n/q_n$ is the $n$th convergent of its continued fraction, the quantity $|q_n \alpha - p_n|$ tends rapidly to zero. Thus the series $\sum_{n \geq 0} |q_n \alpha - p_n|$ converges. This series measures in some sense the “global approximation” of $\alpha$ by its convergents. We then learned from J. Shallit that the quantity $\sum_{n \geq 0} |q_n \alpha - p_n|$ was investigated in several papers [5, 8, 9, 6], where the study of the quantity $\sum_{n \geq 0} (q_n\alpha - p_n)$ (first defined in [28]) can also be found.

It is natural to ask whether the sum of the series $\sum_{n \geq 0} |q_n \alpha - p_n|$ can be expressed in terms of $\alpha$ without explicitly using the convergents, in particular in the case where $\alpha$ has a “nice” continued fraction expansion, e.g., when $\alpha$ is quadratic or when $\alpha = e$.

2 Quadratic numbers

The case of quadratic numbers was addressed in [5] (also see [6]).

Theorem 1 (Elsner) Let $p_n/q_n$ be the $n$th convergent of the continued fraction of $\alpha$. Then the series $\sum_{n \geq 0} (q_n\alpha - p_n)x^n$ converges absolutely at least for $|x| < \frac{1+\sqrt{5}}{2}$ and

$$
\sum_{n \geq 0} (q_n\alpha - p_n)x^n \in \mathbb{Q}[\alpha](x).
$$

In particular (taking $x = -1$), $\sum_{n \geq 0} |q_n \alpha - p_n|$ belongs to $\mathbb{Q}[\alpha]$.

Example 1 (Elsner)

- $\sum_{n \geq 0} |q_n \sqrt{7} - p_n| = \frac{7+5\sqrt{7}}{14}$.
- For any integer $n \geq 1$ we have $\sum_{n \geq 0} |q_n \left(\frac{n+\frac{4+n^2}{2}}{2}\right) - p_n| = \frac{1}{2n+\sqrt{n^2+4n} - 1}$.
- In particular $\sum_{n \geq 0} |q_n \left(\frac{1+\sqrt{5}}{2}\right) - p_n| = \frac{1+\sqrt{5}}{2}$.

3 Powers of $e$

Euler [10] proved that the continued fraction expansion of $e$ is $[2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, ...]$ (sometimes replaced by the not really regular expression $[1, 0, 1, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, ...]$). After Euler, a large number of papers contained the computation of continued fraction...
expansions for some expressions containing $e$ (typically certain powers of $e$ possibly multiplied by some rational numbers, or numbers like $\frac{e^{2k-1}}{e^{2k+1}}$), see in particular [11, 19, 13, 20, 4, 24, 23, 27, 3, 26, 14, 22, 15, 17, 16, 21, 18, 12].

The fundamental theorem we will use here is due to Komatsu [17, Theorem 6, first part]. Komatsu’s theorem contains several previous results.

**Theorem 2 (Komatsu)** Let $\ell \geq 2$ and $s \geq 1$ be two integers. Let $p_n/q_n$ be the $n$th convergent of the continued fraction of

$$se^{1/(\ell s)} = [s, \ell - 1, 1, 2s - 1, 3\ell - 1, 1, 2s - 1, 5\ell - 1, 1, 2s - 1, \ldots, (2k - 1)\ell - 1, 1, 2s - 1, \ldots].$$

Then for $n \geq 0$

$$p_{3n} - se^{1/(\ell s)}q_{3n} = -\frac{1}{(s\ell)^{n+1}} \int_0^1 \frac{x^n(x - 1)^n}{n!} se^{x/(\ell s)}dx$$

$$p_{3n+1} - se^{1/(\ell s)}q_{3n+1} = \frac{1}{s(\ell s)^{n+1}} \int_0^1 \frac{(x + s - 1)x^n(x - 1)^n}{n!} se^{x/(\ell s)}dx$$

$$p_{3n+2} - se^{1/(\ell s)}q_{3n+2} = \frac{1}{s(\ell s)^{n+1}} \int_0^1 \frac{x^n(x - 1)^{n+1}}{n!} se^{x/(\ell s)}dx$$

Let $s \geq 1$ be an integer. Let $p^*_n/q^*_n$ be the $n$th convergent of the continued fraction of

$$se^{1/s} = [s + 1, 2s - 1, 2, 1, 2s - 1, 4, 1, \ldots, 2s - 1, 2k, 1, \ldots].$$

Then $p^*_n/q^*_n = p_{n+2}/q_{n+2}$ with $p_n/q_n$ as above. More precisely for $n \geq 0$

$$p^*_n - se^{1/s}q^*_n = \frac{1}{s^{n+2}} \int_0^1 \frac{x^n(x - 1)^{n+1}}{n!} se^{x/s}dx$$

$$p^*_{3n+1} - se^{1/s}q^*_{3n+1} = -\frac{1}{s^{n+2}} \int_0^1 \frac{x^{n+1}(x - 1)^{n+1}}{(n+1)!} se^{x/s}dx$$

$$p^*_{3n+2} - se^{1/s}q^*_{3n+2} = \frac{1}{s^{n+3}} \int_0^1 \frac{(x + s - 1)x^{n+1}(x - 1)^{n+1}}{(n+1)!} se^{x/s}dx$$

Using Komatsu’s result we can prove the following theorem. First recall that the “error function” $erf$ is defined by $erf(x) := \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$.

**Note** The name “error sum function” (or “error-sum function”) that goes back at least to [28] should not be confused with the name “error function”. To (try to) avoid any ambiguity, we will always write for the latter “error function erf”.

3
Theorem 3 Let \( \ell \geq 2 \) and \( s \geq 1 \) be two integers. Let \( p_n/q_n \) be the \( n \)th convergent of the continued fraction of
\[
se^{1/(\ell s)} = [s, \ell - 1, 1, 2s - 1, 3\ell - 1, 1, 2s - 1, 5\ell - 1, 1, 2s - 1, \ldots, (2k - 1)\ell - 1, 1, 2s - 1, \ldots].
\]
Then
\[
\sum_{n \geq 0} |p_n - se^{1/(\ell s)}q_n| = e^{1/\ell s} \sqrt{\frac{\pi s}{\ell}} \text{erf}(1/\sqrt{\ell s}).
\]

Let \( s \geq 1 \) be an integer. Let \( p^*_n/q^*_n \) be the \( n \)th convergent of the continued fraction of
\[
se^{1/s} = [s + 1, 2s - 1, 2, 1, 2s - 1, 4, 1, \ldots, 2s - 1, 2k, 1, \ldots].
\]
Then
\[
\sum_{n \geq 0} |p^*_n - se^{1/s}q^*_n| = e^{1/s} \sqrt{\pi s} \text{erf}(1/\sqrt{s}) + s(1 - e^{1/s}) - 1.
\]

Proof. It suffices to use Komatsu’s theorem (Theorem 2 above) after writing
\[
\sum_{n \geq 0} |p_n - se^{1/(\ell s)}q_n| = \sum_{0 \leq j \leq 2} \sum_{n \geq 0} |p_{3n+j} - se^{1/(\ell s)}q_{3n+j}|
\]
respectively
\[
\sum_{n \geq 0} |p^*_n - se^{1/s}q^*_n| = |p^*_0 - se^{1/s}q_0| + \sum_{1 \leq j \leq 3} \sum_{n \geq 0} |p^*_{3n+j} - se^{1/s}q^*_n|.
\]

We deduce the following corollary.

Corollary 1 Let \( p^*_n/q^*_n \) be the \( n \)th convergent of the continued fraction of \( e \) (recall that \( e = [2, 1, 2, 1, 1, 4, 1, \ldots, 1, 2n, 1, \ldots] \)). Then
\[
\sum_{n \geq 0} |p^*_n - eq^*_n| = 2e \int_0^1 e^{-t^2} dt - e = e\sqrt{\pi} \text{erf}(1) - e.
\]

Let \( p_n/q_n \) be the \( n \)th convergent of the continued fraction of \( e^{1/\ell} \) (with \( \ell \geq 2 \)). Then
\[
\sum_{n \geq 0} |p_n - e^{1/\ell}q_n| = e^{1/\ell} \sqrt{\frac{\pi}{\ell}} \text{erf}(1/\sqrt{\ell}).
\]

Remark 1 The first result in Corollary 1 above was already obtained by Elsner in [5, p. 2].
Corollary 2 Let $A(\ell, s)$ be defined for positive reals $\ell$ and $s$ by

$$A(\ell, s) := \sum_{n \geq 0} \frac{(-1)^n}{(n + 1)!(2n^2 + 7n + 3)(\ell s)^n}.$$

Then

$$A(\ell, s) = -\frac{3}{10} \ell s + \frac{1}{5} \ell s(2 - \ell s - \ell^2 s^2)e^{-1/\ell s} + \frac{4}{5} \int_0^1 e^{-t^2/\ell s} dt.$$

In particular

$$A(1, 1) = -\frac{3}{10} + 4 \int_0^1 e^{-t^2} dt.$$

so that

$$\sum_{n \geq 0} |q_n e - p_n| = 2 \int_0^1 e^{-t^2} dt - e = \frac{e}{4}(-1 + 10A(1, 1)).$$

Proof. The proof is easy. First write

$$\frac{1}{2n^2 + 7n + 3} = \frac{2}{5(2n + 1)} - \frac{1}{5(n + 3)}.$$

Then introduce the series

$$\sum_{n \geq 0} \frac{(-1)^{n+1}x^{2n+1}}{(n + 1)!(\ell s)^{n+1}(2n + 1)} \quad \text{and} \quad \sum_{n \geq 0} \frac{(-1)^{n+1}x^{n+3}}{(n + 1)!(\ell s)^{n+1}(n + 3)}.$$

The derivative of these series are easily computed. We then need their values at $x = 1$. \qed

Remark 2 It is immediate to use the values of $A(\ell, s)$ to obtain similar formulas for $se^{\ell s}$. We also note we first thought that the quantity $(2n^2 + 7n + 3)$ was somehow crucial in Formula (1): there might ever have been (though it would have been quite surprising) a link with the number of independent parameters of the orthosymplectic group $\text{OSP}(3, 2n)$ which is precisely $(2n^2 + 7n + 3)$ (see, e.g., [2, p. 223]). But this quantity is not crucial; compare with Formula (2) given below which can be proved by using a step of the proof of Corollary 2 above with $s = \ell = 1$ and $x = 1$:

$$\sum_{n \geq 0} \frac{(-1)^{n+1}}{(n + 1)!(2n + 1)} = 1 - e^{-1} - 2 \int_0^1 e^{-t^2} dt.$$

This implies

$$\sum_{n \geq 0} |p_n - \alpha q_n| = e \sum_{n \geq 0} \frac{(-1)^n}{(n + 1)!(2n + 1)} - 1.$$  \hspace{1cm} \hspace{1cm} (2)

Remark 3 The value of $\sum_{n \geq 0} |p_n - \alpha q_n|$ for $\alpha$ equal to one of the above real numbers can also be expressed as another kind of series. Namely a classical series for the error function $\text{erf}$ (see, e.g., [1, 7.1.6, p. 297] reads

$$\text{erf}(z) = \frac{2}{\sqrt{\pi}} e^{-z^2} \sum_{n \geq 0} \frac{2^n}{1 \times 3 \times 5 \cdots \times (2n + 1)} z^{2n+1}.$$
Using Corollary [1] and the notation therein, this gives in particular the following formulas

\[
\sum_{n \geq 0} |p_n^* - e q_n^*| = \sum_{n \geq 0} \frac{2^{n+1}}{1 \times 3 \times 5 \cdots \times (2n+1)} - e = \sum_{n \geq 0} \frac{2^{n+1} n!}{(2n+1)!} - e
\]

(3)

and, for any integer \( \ell \geq 2 \),

\[
\sum_{n \geq 0} |p_n - e^{1/\ell} q_n| = \sum_{n \geq 0} \frac{2^{n+1}}{(\ell n+1) (1 \times 3 \times 5 \cdots \times (2n+1))} = \sum_{n \geq 0} \frac{2^{n+1} n!}{\ell^{n+1} (2n+1)!}.
\]

(4)

Note that the second author obtained Formula (4) empirically. Also note that the digits of the decimal expansion of the right side of Equation (3) (up to the \(-e\) term) is given in [25] as A125961, and that the expansions of the right side of Equation (4) above for \( \ell = 2 \) and \( \ell = 4 \) are given in [25] as A060196 and A214869 respectively.

4 More fun with the error sum function

Formulas similar to the formulas in the previous section can be stated by using results on the convergents for continued fractions with “regular” patterns, in particular at least for (some of) the so-called Hurwitz continued fractions, sometimes also called (regular) continued fractions of Hurwitzian type, see, e.g., [22]. We simply list below results that can be used to yield nice formulas for the error sum function we considered. They give in terms of integrals for some reals \( \alpha \) and their convergents \( p_n/q_n \) the quantity \( p_{an+b} - \alpha q_{an+b} \) (for any \( b \) in a complete system of residues modulo \( a \)) and they are due to Komatsu.

- for \( \alpha = e^{1/s} \), with \( s \) and \( \ell \) any two integers \( \geq 2 \), and \( \alpha = e^{1/s} \), with \( s \geq 2 \), integral expressions for \( p_{3n+j} - \alpha q_{3n+j} \) with \( j \in \{0, 1, 2\} \) are given in [17] Theorem 3, second part.
- for \( \alpha = e^{2/s} \), with \( s \geq 3 \) and odd, integral expressions for \( p_{5n+j} - \alpha q_{5n+j} \) with \( j \in \{0, 1, 2, 3\} \) are given in [14].
- for \( \alpha = \sqrt[3]{(3s+1)/3} \) (resp. \( \alpha = \sqrt[3]{(3s+2)/3} \)), integral expressions for \( p_{9n+j} - \alpha q_{9n+j} \) with \( j \in \{-6, -5, -4, -3, -2, -1, 0, 1, 2\} \) are given in [17];
- for \( \alpha = \sqrt{\frac{u}{v}} \) tanh \( 1/\sqrt{uv} \), integral expressions for \( p_{2n-1} - \alpha q_{2n-1} \) and \( p_{2n} - \alpha q_{2n} \) are given in [16];
- for \( \alpha = \sqrt{\frac{u}{v}} \) tan \( 1/\sqrt{uv} \), integral expressions for \( p_{4n-j} - \alpha q_{4n-j} \) with \( j \in \{0, 1, 2, 3\} \) are given in [16].

The last result we would like to cite here is a nice particular case of a theorem of Hetyei [12, Theorem 2.9] (also see [12, p. 21]) which could be used to compute the error sum function for \( \alpha = \frac{4(11 \sin(1/2) - 6 \cos(1/2))}{53 \cos(1/2) - 97 \sin(1/2)} \).
Theorem 4 (Hetyei) We have the following continued fraction expansion

\[ \frac{4(11 \sin(1/2) - 6 \cos(1/2))}{53 \cos(1/2) - 97 \sin(1/2)} = [4, 3, 4, 4, 4, 4, 4, 5, 4, 6, 4, 7, 4, \ldots]. \]

5 Conclusion

The error sum function of some other continued fractions with “regular” patterns could probably be studied. Another appealing possibility is the definition and study of error sum functions similar continued fractions in the function field case (see in particular [29, 30, 31]). Finally we give a last relation that the second author discovered empirically: we did not locate it in the literature (yet) and did not prove it (yet)

\[ \int_0^1 e^{-t^2} \, dt = \frac{3}{8} + \frac{5/4}{3 + \frac{9}{21 + \frac{288}{63 + \frac{n(n+2)(2n-1)^2}{(2n+5)(n^2+n+1)+\ldots}}}}. \]

Acknowledgements We want to warmly thank J. Shallit who indicated to us the papers [5, 8, 9, 6].

Addendum After we posted the first version of this paper on ArXiv, C. Elsner kindly sent us the preprint [7], which was written a few months ago, and where the reader can find some results in another direction (limit formulas, differential equations, algebraic independence results, relations to Hall’s theorem) but also a proof of the result in Corollary 1

\[ \forall \ell \geq 2, \sum_{n \geq 0} |p_n - e_1/\ell q_n| = e_1/\ell \sqrt{\frac{\pi}{\ell}} \text{erf}(1/\sqrt{\ell}). \]
