Biomass feedstocks are promising candidates of renewable clean energy. The development and utilization of biological energy is in line with the concept of sustainable development and circular economy. As an important platform chemical, γ-valerolactone (GVL) is often used as green solvent and biofuel additive. Regarding this, the efficient synthesis of GVL from biomass derivative furfural (FF) has attracted wide attention recently. However, suitable catalyst with appropriate acid-base sites is required due to the complex reaction progress. In this Mini Review, the research progress of catalytic synthesis of GVL from furfural by Zr/Hf-based catalysts was reviewed. The different effects of Lewis acid-base and Brønsted acid sites in the catalysts on each steps in the reaction process were discussed firstly. Then the effects of regulation of acid-base sites in the catalysts was also studied. Finally, the advantages and challenges of Zr/Hf-based catalysts in FF converted to GVL system were proposed.

Keywords: biomass, furfural, γ-valerolactone, Zr/Hf-based catalysts, active site regulation

INTRODUCTION

Although the exploration and utilization of fossil energy promote the development of human society, it also causes nonnegligible harm to the environment, which makes people focus on available energy to reduce dependence on fossil energy (Roman-Leshkov et al., 2007; Luterbacher et al., 2014; Zhang et al., 2019). Biomass, as the only renewable organic carbon source, has received extensive attention due to its abundance, cheapness, and availability (Li et al., 2014; Zhao et al., 2019; Li H. et al., 2020). A variety of valuable compounds (e.g., xylose, furfural, furfuryl alcohol, levulinic acid and its esters, and γ-valerolactone) can be obtained from biomass (Liu et al., 2015; Li F. et al., 2017; Li H. et al., 2017; Lingaiah, 2018; Li et al., 2019a; Luo et al., 2019). Among them, γ-valerolactone (GVL) has excellent physical and chemical properties such as high boiling point (207°C), low melting point (31°C), and low toxicity (LD₅₀ = 8,800 mg/kg). It can be used as a green organic solvent in a variety of reactions, and has broad application prospects in the organic synthesis, biorefinery, and food industry (Yan et al., 2015; Ye et al., 2020b). In addition, GVL can be further converted into various valerate esters (these have been identified as new generation biofuels), which can be used to synthesize various biomass-based liquid fuels (Yu et al., 2019).

In recent years, the related research on the synthesis of GVL mainly focuses on the direct hydrogenation or catalytic transfer hydrogenation (CTH) with levulinic acid and its esters as substrates. Both noble metal (Ru, Rh, Pt, Pd, Au) catalysts and non-precious metal (Ni, Cu, Co.)
Catalysts have been used for the hydrogenation of LA to GVL (Yuan et al., 2013; Luo et al., 2014; Molleti et al., 2018). Obregon et al. studied the liquid phase hydrogenation of LA on Ni/Al2O3, after reacting at 250°C and 6.5 MPa H2 pressure for 2 h. The yield of GVL reached 92% (Obregon et al., 2014). Although high yield was achieved by hydrogenation, however, the use of pressurized hydrogen gas is often associated with potential explosion hazard, so the transfer hydrogenation strategy for the synthesis of GVL from LA has been developed. Numerous supported Ru, Pd, Ni, and Cu catalysts were investigated for this reaction (Dutta et al., 2019; Ye et al., 2020b). Fu et al. firstly reported a non-precious skeletal Ni catalyst which could effectively catalyze the reaction with i-PrOH as H-donor at room temperature over 9 h (Yang et al., 2013). In addition, different hydrogen donors such as formic acid, hydrosilicon and alcohol have been exploited for this transformation, compared to other H-donors, the secure, safe and easily operated alcohol not only can act as H-donor, but also can serve as a solvent, furthermore, it can enhance the selectivity in the hydrogenation process, too (He et al., 2020a). Compared with levulinic acid, furfural (FF) is more available from biomass feedstocks, so the researchers considered FF directly as a feedstock for GVL production (Bui et al., 2013).

The conversion of FF to GVL requires a series of cascade reactions (Figure 1) such as CTH, etherification, ring-opening, partial hydrogenation, and cyclization reaction (Zhu et al., 2016). Such complex reaction processes require higher performance catalysts. Therefore, it is necessary to fully consider both the structure and acid-base properties of the catalyst to improve the catalyst activity. Since Zr/Hf-based catalysts show excellent catalytic performance in CTH reactions and are more economical than precious metals, more and more researchers applied them to the reaction of converting GVL from FF (Li et al., 2016; Wu et al., 2018; Zhou et al., 2019a; Wang et al., 2019).

At present, some excellent reviews are related to the synthesis of GVL, Zr/Hf-based catalysts showed good performance, as shown in Table 1. Zhu et al. first used Au/ZrO2 (providing Lewis acid-base sites) with ZSM-5 (providing Bronsted acid sites) to catalyze the conversion of FF to GVL (Zhu et al., 2016). The experimental results showed that when Au/ZrO2 was used as the catalyst, FF was almost completely converted to furfuryl alcohol (FA) (99.0% yield) rather than GVL. Similarly, no GVL was detected when only ZSM-5 was used as the catalyst. These results showed that the presence of both Lewis acid-base and Bronsted acid sites in the catalyst was necessary to successfully catalyze the conversion of FF to GVL. Rojas-Buzo et al. found that the prepared Hf-MOF-808 catalyst could successfully catalyze the CTH reaction of FF to FA and levulinic acid to obtain GVL, but could not directly catalyze the synthesis of GVL from FF (Rojas-Buzo et al., 2018). However, when the Hf-MOF-808/Al-β zeolite (containing Bronsted acid sites) combined catalyst was applied to this reaction, a good 75% yield of GVL was obtained at 120°C for 48 h. This result strongly shows that Bronsted acid is crucial to the ring-opening process involved in the conversion of FA to levulinate in this reaction process. Although combined catalyst system could improve the reaction yield, the catalyst preparation process becomes complicated and the production cost increases.

To simplify the preparation process of the catalyst and increase the reaction yield of GVL, the exploration of bifunctional catalysts containing both Lewis and Bronsted acid sites has attracted more and more attention. Bui et al. first used the physical mixture of Zr-Beta and mesoporous Al-MFI zeolite as Lewis acid and Bronsted acid catalysts to convert FF into GVL in one-pot (Bui et al., 2013). Later, Iglesias et al. synthesized a bifunctional catalyst containing...
both Lewis acid and Bronsted acid by loading ZrO₂ on SBA-15 zeolite (Iglesias et al., 2018). The catalyst can control the strength of Lewis acid and Bronsted acid by changing the number of ZrO₂ layers. Kinetic studies showed that the strength of Lewis acid in the catalyst had an important influence on the distribution of products. Strong Lewis acid sites promote etherification and isomerization of FA rather than MPV reduction. Srinivasa Rao et al. used the impregnation method to load different proportions of ZrO₂ and phosphotungstic acid (TPA) on β-zeolite to further study the effect of Lewis/Bronsted acid content in the catalyst on the yield of GVL (Srinivasa Rao et al., 2021). The experimental results show that more Bronsted acid sites and fewer Lewis acid sites in the catalyst are more conducive to the production of levulinic acid ester rather than GVL. Therefore, the key to obtain high yield GVL is to control the Lewis acid-base and Bronsted acid sites with appropriate strength and number of bifunctional catalysts. Very recently, Tan et al. synthesised a variety of novel coordination organophosphate–Hf polymers from vinylphosphonic acid (VPA), p-toluenesulfonic acid (p-TSA), and HCl. Specifically, VPA–Hf(1 : 1.5)–0.5 with an appropriate L/B acid ratio of 5.3 and was found to exhibit superior performance in the one-step conversion of furfural (FF) to γ-valerolactone (GVL) in a high yield of 81.0%, with a turnover frequency of 5.0 h⁻¹. (Tan et al., 2022).

Zeolite with a complex microporous structure has an open framework with regular pore size and appropriate size, which is conducive to mass transfer and is easy to adjust acidity (Wang et al., 2017; Wang et al., 2020; Peng et al., 2020; Chai et al., 2021). Since zeolite has these unique advantages, the existing catalysts for FF conversion to GVL are mostly prepared with various zeolites as supporter. These catalysts mainly change the content of Lewis acid sites in the catalysts by changing the metal loading, and different kinds and concentrations of acids are used to control the content of Bronsted acid in the catalysts (Srinivasa Rao et al., 2019; Winoto et al., 2019; He et al., 2020a; Ye et al., 2020a). He et al. adjusted the content of Lewis/Bronsted acid in the catalyst by adding different amounts of ZrOCl₂·8H₂O (He et al., 2020b). The more Zr is loaded in the catalyst, the higher the molar ratio of Lewis acid to Bronsted acid is. NH₃-TPD results showed that with the increase of Zr loading in the catalyst, the total number of acid sites in the catalyst increased gradually. But excessive Zr loading will produce zirconia clusters, which will reduce the activity of the catalyst. Li et al. treated the catalyst by soaking DUT-67 (Hf) in different concentrations of sulfuric acid solution to change the content of Bronsted acid (Li W. et al., 2019). The results showed that with the increase of sulfuric acid concentration, the total content of acid sites in the catalyst increased continuously, but excessive Bronsted acid in the catalyst would lead to side reactions, which decreased the yield of GVL. Srinivasa Rao et al. loaded phosphotungstic acid (TPA) and ZrO₂ with different contents inside and outside the pores of SBA-15, respectively (Srinivasa Rao et al., 2021). Under the premise of keeping the total Lewis acid content in the catalyst unchanged, the molar ratio of Lewis acid to Bronsted acid in the catalyst was adjusted by controlling the amount of ZrO₂ and TPA. The catalyst showed excellent catalytic activity, and the yield of GVL reached 90% at 170°C for 10 h.

In addition to using zeolite as a carrier, bifunctional materials prepared with ligands base on biomass derivatives are also applied to the conversion of FF to GVL. Using alizarin red S

### Table 1: Catalytic production of γ-valerolactone (GVL) from furfural (FF) over Zr/Hf-based catalysts.

| Entry | Catalysts | Acidity (mmol/g) | L/B | H-donor | Adjustment of active sites | Reaction conditions | GVL yield (%) | Ref |
|-------|-----------|-----------------|-----|---------|---------------------------|-------------------|--------------|-----|
| 1     | Zr-Beta + Al-MFI-ns | -- -- | 2-butanol | Lewis acid site and Bronsted acid site are independent of each other, which can adjust the content and strength of Lewis acid and Bronsted acid in the catalyst respectively | 120°C, 48 h | 78 | Bui et al. (2013) |
| 2     | Au/ZrO₂+ZSM-5 | -- -- | 2- propanol | Lewis acid site and Bronsted acid site are independent of each other, which can adjust the content and strength of Lewis acid and Bronsted acid in the catalyst respectively | 120°C, 30 h | 80.4 | Zhu et al. (2016) |
| 3     | Hf-MOF 808+Al-β zeolite | -- -- | 2- propanol | With the increase of the number of ZrO₂ film layers supported on the surface of SBA-15, the strength of Lewis acid in the catalyst increases, while the strength of Bronsted acid decreases | 120°C, 48 h | 75 | Rojas-Buzo et al. (2018) |
| 4     | ZrO₂-SBA-15(2) | 0.32 0.08 | 2- propanol | Change the loading of Zr in the catalyst | 170°C, 7 h | 37 | Iglesias et al. (2018) |
| 5     | Zr-KIT-5 | 1.86 6.5 | 2- propanol | Change the ratio of zeolite and NH₄H₂PO₄ in the catalyst | 180°C, 6 h | 40.1 | He et al. (2020b) |
| 6     | HZ-ZrP 1-5 | 0.87 4.1 | 2- propanol | Change the ratio of zeolite and NH₄H₂PO₄ in the catalyst | 185°C, 18 h | 64.2 | Ye et al. (2020a) |
| 7     | HPW/Zr-Beta | 0.78 3.2 | 2- propanol | Use different acid treatment catalysts | 160°C, 24 h | 68 | Winoto et al. (2019) |
| 8     | 20%Zr-5%Hf-β zeolite | 1.67 1.53 | 2- propanol | Adjust the ratio of TPA and Zr in the catalyst | 170°C, 10 h | 90 | Srinivasa Rao et al. (2019) |
| 9     | DUT-67(Hf)-0.06 | 1.28 -- | 2- propanol | Treatment of DUT-67-(Hf) with different concentrations of sulfuric acid | 180°C, 8 h | 70.7 | Li et al. (2019b) |
| 10    | FM-Zr-APR | 0.55 0.23 | 2- propanol | Modification of the catalyst with formic acid | 160°C, 8 h | 72.4 | Peng et al. (2021) |
| 11    | ZPS-1.0 | -- 3.25 | 2- propanol | Change the amount of Zr in the catalyst | 150°C, 18 h | 80.4 | Li et al. (2021c) |
Avoid the use of dangerous high-pressure \( H_2 \) and corrosive formic acid in the reaction process are completed by MPV reduction reaction, preparation process cannot be ignored. The key CTH reactions are generally completed through a six-membered ring transition state. Lewis acid sites are usually used to activate \( H_2 \) on the aldehyde group and \( C \) connected with the alcohol hydroxyl group. Lewis base sites are mainly used to activate the alcohol hydroxyl group, making \( H_2 \) easier to remove. Finally, the transfer hydrogenation process is completed through the six-membered ring transition state (Li et al., 2018; Zhou et al., 2019b; Li et al., 2019c). Jariyana et al. found that \( Hf-Uio-66 \) has lower activation energy (13.5 kcal/mol vs 14.9 kcal/mol) than \( Zr-Uio-66 \) based on density functional theory (DFT) (Sittiwong et al., 2021). It is due to \( Hf \) having stronger Lewis acidity, \( Hf \) has better performance than \( Zr \) in CTH reaction under the same preparation conditions (Luo et al., 2014; Xie et al., 2016; Injongkol et al., 2017; Li X. et al., 2020). Tan et al. prepared a new coordination organic phosphate-based \( Hf \) polymer \( VPA-Hf(1:1.5)\)-0.5, which showed good activity for one-pot cascade conversion of FF to GVL. By controlling the ratio of vinyl phosphoric acid, \( p \)-toluenesulfonic acid and \( HfCl_4 \), the content of Lewis acid sites and B acid sites can be accurately adjusted, and the E factor value (0.19) shows that the conversion process mediated by the catalyst is ecologically friendly.

EFFECT OF REACTION PARAMETERS

The reaction can be carried out under mild conditions (120°C) when combined catalysts were used (Table 1). For bifunctional catalysts containing both Lewis acid and Bronsted acid, although the preparation of the catalyst is simpler and the cost is reduced, a higher reaction temperature (150–180°C) is often required to ensure the sufficient progress of the reaction. This may due to the dependent active sites can also effectively reduce the adverse effects of steric hindrance in the reaction process, so the reaction can be carried out under mild conditions. However, the disadvantages such as excessively long reaction time and more tedious catalyst preparation process cannot be ignored. The key CTH reactions in the reaction process are completed by MPV reduction reaction, and more green and safe alcohols are usually used as \( H \)-donors to avoid the use of dangerous high-pressure \( H_2 \) and corrosive formic acid. In general, the \( \beta-H \) of secondary alcohols is easier to be removed from the transition state, so the hydrogen supply capacity of secondary alcohols is stronger than that of primary alcohols (Elsayed et al., 2020; Li J. et al., 2021). However, the steric hindrance of secondary alcohols will gradually increase with the extension of the carbon chain, and excessive steric hindrance is not conducive to the formation of stable transition states, thereby reducing the hydrogen supply capacity (Li M. et al., 2021; Li W. et al., 2021). Therefore, due to the small steric hindrance, 2-propanol was used as the \( H \)-donor to prepare GVL in most cases. In addition, the reusability of the catalyst is also an important aspect to evaluate the catalytic system. However, humus is usually formed during the reaction, which not only affects the carbon balance of the reaction system but also reduces the activity of the catalyst during recycling. Usually, calcination can remove the humus attached to the catalyst and restore the activity of the catalyst (Iglesias et al., 2018; Ye et al., 2020a; Tang et al., 2021). In addition, the catalyst may also have active site leaching during recycling, and it needs to be treated with acid before being put into the next recycling (Li W. et al., 2019).

CONCLUSION AND OUTLOOK

GVL is an important biomass derivative, which can be used as green solvents and biofuels. Highly efficient cascade conversion of FF to GVL presents great challenges due to complex reaction processes and high requirements for catalyst performance. In this mini-review, the influence of the catalyst preparation process on catalyst activity was reviewed, and the reaction parameters such as temperature and \( H \)-donor were also discussed. The acid-base properties of the catalyst have a great influence on its catalytic performance. The Lewis acid-base sites in the catalyst are mainly used to catalyze the CTH reaction, and the crucial ring-opening reaction needs to be carried out in the presence of Bronsted acid sites. There is no doubt that higher acid content in the catalyst can provide more active sites, but the imbalance of Lewis acid and Bronsted acid ratio can easily lead to undesirable side reactions. It may lead to carbon imbalance and GVL yield reduction, while the formation of humus attached to the catalyst will reduce the reusability of the catalyst.

Renewable biomass-based carbonaceous support catalysts have great potential for the green synthesis of GVL. Organic hybrid materials have proved to have good activity for CTH reaction, but the Bronsted acid sites are usually not sufficient to catalyze the ring-opening reaction. Therefore, how to improve the strength of Bronsted acid while ensuring the stability of the catalyst structure is the challenge that must be overcome for its application for FF synthesis to GVL. In addition, the accurate control of the strength and content of each active site in the catalyst can better control the reaction process, which is crucial to improving the yield of GVL. Due to the strong Lewis acidity of \( Zr/Hf \) materials, \( Zr/Hf \)-Based Catalysts showed high performance in the reaction of convert FF to GVL. However, most of the exiting catalytic system still suffered from high temperature as well as not so excellent yield, so it is still a challenge to design novel and efficient catalyst for this reaction.
