ABSTRACT

Background: Silicosis is an occupational lung disease caused by inhalation of dust containing crystalline silica particles of size 0.5-5 microns in diameter. It commonly occurs in workers involved in quarrying, mining, sandblasting, tunneling, foundry work and ceramics. Pneumothorax is one of the complications of silicosis. The occurrence of pneumothorax in a patient with silicosis is a rare event, but it may be fatal. The incidence of secondary spontaneous pneumothorax (SSP) in silicosis as such is not known. This study aims to report the cases of secondary spontaneous pneumothorax in patients of silicosis in Southern part of Rajasthan.

Methods: 50 patients of silicosis established by historical, clinical evaluation and radiological evidence with increased dyspnoea were included in the study. In all patients Chest X ray was done immediately.

Results: Among 50 patients of silicosis with increased dyspnoea, Chest X ray showed pneumothorax in 20 patients of which 4 had bilateral pneumothorax, 7 had right pneumothorax and 9 had left pneumothorax. The mean duration of exposure to silica particles was 10 years (5 to 15 years). All the patients had various degrees of dyspnoea and chest pain. Tube thoracostomy was performed in 15 patients while 5 patients were managed conservatively with oxygen and bronchodilators.

Conclusions: Our study showed an increased incidence of secondary pneumothorax in silicosis patients. The occurrence of pneumothorax, though rare in silicosis is a potentially life-threatening complication and may cause serious morbidity and mortality. The patients of silicosis who develop sudden onset of dyspnoea should be promptly investigated for this complication.

Keywords: Dyspnoea, Secondary spontaneous pneumothorax, Silicosis, Silica particles

INTRODUCTION

Silicosis is an occupational lung disease caused by the inhalation and accumulation of crystalline silica particles in the lung. It is the most prevalent type of pneumoconiosis. It is characterized by symptoms of shortness of breath, cough, chest pain. It commonly occurs in workers involved in quarrying, mining, sandblasting, tunneling, foundry work and ceramics. Exposure to large amounts of free silica can go unnoticed because silica is odorless, non-irritant and does not cause any immediate health effects. As silicosis is incurable, clinical management includes removing the worker from the industry and giving symptomatic treatment. Public health goals are to detect early cases through monitoring of currently and formerly exposed workers, to establish surveillance programmes, to slow progression and to reduce disability.

Pleural involvement, including pleural effusion, pleural thickening, or pneumothorax, is rarely seen in silicosis. Pneumothorax is one of the most important complications...
of silicosis associated with pleura. In silicosis, the pneumothorax is usually unilateral and may be fatal.\(^4,6\) This study aims to report secondary spontaneous pneumothorax (SSP) in silicosis patients.

**METHODS**

50 patients of silicosis who visited chest OPD at Geetanjali Hospital, Udaipur with increased symptoms of dyspnoea and chest pain were enrolled in the study. Such patients with history of working in stone mines and radiological evidence of silicosis were thoroughly interrogated regarding occupation, nature of work, duration of exposure to dust and silica particles before inclusion in the study. These patients were working in the mines near Udaipur region in Rajasthan. In all the cases, pneumothorax was diagnosed clinically by auscultation and then confirmed radiologically by recent Chest X-ray.

**RESULTS**

Among 50 patients of silicosis, 45 were males and 5 patients were females. 30 male patients had history of smoking. The mean duration of exposure to silica particles was 10 years (5 to 15 years). All the patients were diagnosed on basis of occupational, historical, clinical and radiological evaluation. All of the patients had varying degrees of dyspnoea and chest pain which were increased recently. Chest X rays of all patients revealed bilateral, widespread reticulonodular and nodular appearances. Bilateral hilar popcorn calcification was seen in 1 patient.

Progressive massive fibrosis lesions were seen in 10 patients who had history of long and continuous exposure to silica particles. Pneumothorax was seen bilaterally in 4 cases, right side in 7 cases and left side in 9 cases. So, the overall incidence of pneumothorax among silicosis patients was 40% (20/50) which is higher as compared to the evidences till now. All the patients who developed pneumothorax were smokers. Tube thoracostomy was performed in 15 patients while 5 patients with minimal pneumothorax were managed conservatively with oxygen and bronchodilators.
prevalence of pneumothorax was 40% (20/50), which is higher as compared to the evidences till now. All the patients with pneumothorax in our study were known smokers. So, smoking could be one of the etiological factor for SSP in our study. Though it remains unclear whether smoking predisposes exposed miners to silicosis or nonspecific radiographic changes from smoking are misinterpreted as silicosis.11 Mohebbi et al reported that in acute and accelerated silicosis, there is a significant association between the presence of bulla and secondary spontaneous pneumothorax.12

As in other cases of SSP, pneumothorax in silicosis patients requires an aggressive approach to treatment. However, there is no accepted consensus for the treatment. In our study, Tube thoracostomy was performed in 15 patients while 5 patients with minimal pneumothorax were managed conservatively with oxygen and bronchodilators.

CONCLUSION

Our study showed an increased prevalence of secondary pneumothorax in silicosis patients. Smoking may be a risk factor for development of pneumothorax. Pneumothorax in silicosis patients can cause serious morbidity and mortality. Although the occurrence of SSP is rare in silicosis, but whenever chest pain and dyspnoea occur suddenly or has increased recently in a silicosis patient, the patient should be promptly investigated and pneumothorax should be kept in mind.
