Abstract
A problem of finding stationary states of open quantum systems is addressed. We focus our attention on a generic type of open system: a qubit coupled to its environment. We apply the theory of block operator matrices and find stationary states of two-level open quantum systems under certain conditions applied on both the qubit and the surrounding.

1. Introduction

In quantum mechanics, the density operator \( \rho \) of a quantum system is called a stationary state if \( [H, \rho] = 0 \), where \( H \) is a given time-independent Hamiltonian of the system. Since \( \rho \) satisfies the Liouville–von Neumann equation \( i\hbar \partial_t \rho = [H, \rho] \), it is clear that stationary states are invariant with respect to the transformation \( \rho \mapsto U_t \rho U_t^\dagger \), where \( U_t = \exp(-iHt) \) is the time evolution operator. In other words, stationary states do not change during the time evolution.

For low-dimensional closed systems, the stationary states can be obtained relatively easily [1, 2]. It is a common situation that a small quantum system is immersed in another, mostly large, system called the environment [3]. Such an open system does not evolve unitarily in time. An analysis of open quantum systems [4, 5] is much more complicated as they are a stage of a variety of physical phenomena [6–8]. The famous decoherence process [9] may serve as an example. In open quantum systems the character of potentially existing stationary states is not obvious.

There are various physical problems related to the properties of open quantum systems, which has already been addressed and intensively discussed (see e.g. [10, 11]). The existence and properties of stationary states have significant importance in quantum information processing and quantum theory itself; nevertheless, the procedure of deriving such states
has not been studied in a full detail and many open questions remain, e.g.

(i) do the stationary states exist for a given open system?
(ii) what features of a given model are responsible for the existence of such states?
(iii) how such states can be constructed?

The answers to the above questions are still incomplete. For example, it is known that the stationary states exist for completely positive (CP) evolution of the open system; this fact follows directly from Schauder’s fixed point theorem. However, this is only an existential result and so far there are no available methods to determine explicit form of stationary states. Furthermore, the very existence of the stationary states in general case is an open problem, e.g., in the presence of initial system–environment correlations.

The primary goal of the presented work is to propose a method of calculating the stationary states in the case of two-dimensional open quantum systems. The theory of block operator matrices is adapted to achieve this goal. In particular, we use the Riccati operator equation to solve the eigenproblem for the total Hamiltonian. It is shown how to derive the stationary states by using the solution of the equation.

2. Block operator matrix approach

We begin with a brief review of the block operator matrices approach to the problem of decoherence in the case of a single qubit. Let $H$ be the Hamiltonian of the total system. We will assume that it has the following form:

$$H = H_Q \otimes I_E + I_Q \otimes H_E + H_{\text{int}},$$

(1)

where $H_Q$ and $H_E$ represent the Hamiltonian of the qubit and the environment, respectively, while $H_{\text{int}}$ specifies the interaction between the systems. The Hamiltonian $H$ acts on the Hilbert space $\mathcal{H}_{\text{tot}} = \mathbb{C}^2 \otimes \mathcal{H}_E$, where $\mathcal{H}_E$ is the Hilbert space (possibly infinite-dimensional) related to the environment. $I_Q$ and $I_E$ are the identity operators on $\mathbb{C}^2$ and $\mathcal{H}_E$, respectively.

Since the isomorphism $\mathbb{C}^2 \otimes \mathcal{H}_E \cong \mathcal{H}_E \oplus \mathcal{H}_E$ holds true, the Hamiltonian (1) admits the block operator matrix representation

$$H = \begin{bmatrix} H_L & V \\ V^\dagger & H_R \end{bmatrix}$$

(2)

on $\mathcal{D}(H) = (\mathcal{D}(H_L) \cap \mathcal{D}(V^\dagger)) \oplus (\mathcal{D}(V) \cap \mathcal{D}(H_R))$.

All the entries of (2) are operators acting on $\mathcal{H}_E$. Moreover, the diagonal entries, i.e., $H_L$ are self-adjoint. In this paper, we will focus on the case in which $V$ is bounded; thus, $V^\dagger$ is bounded as well; however, no assumption on the boundedness of $H_L$ is made. Under these circumstances we have $\mathcal{D}(H) = \mathcal{D}(H_L) \oplus \mathcal{D}(H_R)$, where domains $\mathcal{D}(H_L)$ are assumed to be dense in $\mathcal{H}_E$.

The generally accepted procedure to obtain the reduced time evolution of the open system, the so-called reduced dynamics, reads

$$\rho_t = \text{Tr}_E[\{U_t(\rho_0)U_t^\dagger\}] \equiv T_t(\rho_0).$$

(3)

Above, $\rho_0$ specifies the state of the open system at $t = 0$. The map $\Phi$ assigns to each initial state $\rho_0$ a single state $\Phi(\rho_0)$ of the total system. The assignment map must be chosen properly so that $T_t$ can be well defined [24–26]. For instance, if no correlations between the systems are initially present, then $\Phi(\rho_0) = \rho_0 \otimes \omega$ for some initial state of the environment $\omega$. It is worth mentioning that if the initial state cannot be factorized, the definition of $\Phi$ is not accessible [27]. The unitary operator $U_t = \exp(-iHt)$ describes the time evolution of the total system.
The map \( \text{Tr}_E \) denotes the so-called partial trace
\[
\text{Tr}_E \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix} = \begin{bmatrix} \text{Tr}M_{11} & \text{Tr}M_{12} \\ \text{Tr}M_{21} & \text{Tr}M_{22} \end{bmatrix} \in M_2(\mathbb{C}), \quad \text{where} \quad M_{ij} \in \mathcal{T}(\mathcal{H}_E).
\] (4)

\( \text{Tr} \) refers to the usual trace operation on \( \mathcal{H}_E \); \( \mathcal{T}(\mathcal{H}_E) \) denotes the Banach space of the trace class operator with the trace norm \( \|A\|_1 = \text{Tr}(\sqrt{AA^\dagger}) \), whereas \( M_2(\mathbb{C}) \) is the Banach space of \( 2 \times 2 \) complex matrices. Note that the partial trace is a linear operation transforming the block operator matrices (square brackets) to the ordinary matrices (round brackets).

3. Main results

Fixed point theorems like Banach or Schauder indicate the existence of stationary states for a given evolution \( T_t \). However, there is no general analytical procedure to obtain the explicit form of such states. In this section we propose a method of deriving stationary states for two-level open quantum systems. The generalization to the higher dimensions seems to be possible. However, we will not deal with this issue in this paper. We begin with some definitions.

**Definition 1.** The density matrix \( \rho \) is said to be a stationary state if it is invariant with respect to reduced evolution, \( T_t(\rho) = \rho \).

**Definition 2.** Let \( X \) be an operator acting on the Hilbert space \( \mathcal{H}_E \). The subset \( \Gamma_X \) of \( \mathcal{H}_E \oplus \mathcal{H}_E \) defined as
\[
\Gamma_X := \left\{ \begin{bmatrix} |\psi\rangle \\ X|\psi\rangle \end{bmatrix} : |\psi\rangle \in D(X) \subset \mathcal{H}_E \right\}
\] (5)
is said to be the graph of \( X \).

The graph of a linear and closed operator is a subset of the Hilbert space, which is a Hilbert space itself equipped with the inner product
\[
\langle \Psi_1|\Psi_2 \rangle = \langle \psi_1|\psi_2 \rangle + \langle \phi_1|\phi_2 \rangle, \quad |\Psi_i\rangle = \begin{bmatrix} |\psi_i\rangle \\ |\phi_i\rangle \end{bmatrix} \in \Gamma_X \quad (i = 1, 2).
\] (6)

\( \langle \psi|\phi \rangle \) is an inner product on \( \mathcal{H}_E \). It is a known fact (see lemma 5.3 in [28]) that the graph \( \Gamma_X \) is \( \mathcal{H} \)-invariant, that is, \( \mathcal{H}(\Gamma_X \cap D(\mathcal{H})) \subset \Gamma_X \) if and only if \( X \) is a bounded solution (with \( \text{Ran}(X|_{D(\mathcal{H})}) \subset D(\mathcal{H}) \)) of the Riccati equation
\[
 XV + XH - H - X - V^\dagger = 0 \quad \text{on} \quad D(\mathcal{H}).
\] (7)

Along with the equation above we introduce the dual Riccati equation, namely
\[
 YV^\dagger Y + YH - H - V = 0 \quad \text{on} \quad D(\mathcal{H}).
\] (8)

It is proved in [28] that \( Y = -X^\dagger \) is a solution (with \( \text{Ran}(X^\dagger|_{D(\mathcal{H})}) \subset D(\mathcal{H}) \)) of (8) if and only if the orthogonal complement of \( \Gamma_X \), i.e. the subspace
\[
\Gamma_X^\perp = \left\{ \begin{bmatrix} -X^\dagger |\psi\rangle \\ |\psi\rangle \end{bmatrix} : |\psi\rangle \in D(X^\dagger) \subset \mathcal{H}_E \right\},
\] (9)
is \( \mathcal{H} \)-invariant. It is straightforward to see that a bounded operator \( X \) solves (7) if and only if \( Y = -X^\dagger \) is a solution of (8). Therefore, \( \Gamma_X \) and \( \Gamma_X^\perp \) are \( \mathcal{H} \)-invariant if and only if \( X \) is a bounded solution of (7). In other words, \( \Gamma_X \) is the reducing subspace of \( \mathcal{H} \) if and only if \( X \) is a bounded solution of (7). From considerations above it also follows that \( \Gamma_X \) and \( \Gamma_X^\perp \) are \( U_t \)-invariant.
Definition 3. Elements from the graph and its orthogonal complement are denoted by \(|X_\psi\rangle\) and \(|X^\psi\rangle\), respectively. The Riccati states are defined as \(\rho_\psi = \text{Tr}_E(\varrho_\psi)\) and \(\rho^\psi = \text{Tr}_E(\varrho^\psi)\), where \(\varrho_\psi := |X_\psi\rangle\langle X_\psi|\) and \(\varrho^\psi := |X^\psi\rangle\langle X^\psi|\).

The vectors \(|X_\psi\rangle\) and \(|X^\psi\rangle\) are not normalized with respect to the norm induced by the inner product (6). Moreover, the states \(\varrho_\psi\) and \(\varrho^\psi\) are not factorizable (i.e. correlations occur), unless \(X|\psi\rangle \sim |\psi\rangle\) and \(X^1|\psi\rangle \sim |\psi\rangle\), respectively. However, they are \(U_i(\cdot)U_i^\dagger\)-invariant, which is obvious because the vectors \(|X_\psi\rangle\) and \(|X^\psi\rangle\) are \(U_i\)-invariant. As a consequence, the Riccati states \(\rho_\psi\) and \(\rho^\psi\) are \(T_t\)-invariant, where the map \(T_t\) has been defined in (3). Therefore, the set of all the Riccati states is invariant under the time evolution. Nevertheless, the Riccati states are not the stationary states, in general. However, we show that the latter can be found among the Riccati states. To be specific, we will prove the following

Theorem 1. Let \(X\) be a bounded solution of the Riccati equation (7). Then,

(i) the Riccati state \(\rho_\psi\) is a stationary state if the vector \(|\psi\rangle\) is an eigenvector of the operator \(Z_\psi \equiv H_\psi + VX : D(H_\psi) \to \mathcal{H}_E\).

(ii) the Riccati state \(\rho^\psi\) is a stationary state if the vector \(|\phi\rangle\) is an eigenvector of the operator \(Z_\phi \equiv H - V^1X^1 : D(H) \to \mathcal{H}_E\).

Proof. Let \(Z_\psi|\psi\rangle = \lambda|\psi\rangle\) for \(\lambda \in \mathbb{C}\) and \(|\psi\rangle \in D(H_\psi)\). From (7) we obtain that \(V^1 + H_\psi X = XZ_\psi\); hence, in view of (2) the last equality leads to \(H|X_\psi\rangle = \lambda|X_\psi\rangle\). Thus, the vector state \(|X_\psi\rangle\) is the eigenvector of the Hamiltonian with the corresponding eigenvalue \(\lambda\). Since \(H\) is self-adjoint we have \(\lambda \in \mathbb{R}\) and in consequence \(U_i\varrho_\psi U_i^\dagger = \varrho_\psi\), where \(\Phi(\varrho_\psi) = \varrho_\psi\), which ultimately leads to \(T_t(\rho_\psi) = \rho_\psi\).

In a comparable manner, we have \(H|X^\psi\rangle = \xi|X^\psi\rangle\) for \(\xi \in \mathbb{R}\) and \(|\phi\rangle \in D(H)\) so that \(Z_\phi|\phi\rangle = \xi|\phi\rangle\). Just as before \(U_i\Phi(\rho^\psi)U_i^\dagger = \rho^\psi\); therefore, \(T_t(\rho^\psi) = \rho^\psi\). \(\square\)

At this point, some remarks, regarding the theorem given above, should be made.

Remark 1. The question whether all stationary states are Riccati states or if it is possible that stationary states exist that are not Riccati states is still open.

Remark 2. Since the space \(\Gamma_X\) is closed, we have the following decomposition \(\mathcal{H}_{\text{tot}} = \Gamma_X \oplus \Gamma_X^\perp\). Thus, the total Hamiltonian is similar to certain block diagonal operator matrix, \(S^{-1}\mathcal{H}S = \mathcal{H}_d\), where

\[
\mathcal{H}_d = \begin{bmatrix}
Z_\psi & 0 \\
0 & Z_\phi
\end{bmatrix}
\quad \text{with} \quad D(Z_\psi) = D(H_\psi) \quad \text{and} \quad S = \begin{bmatrix}
I & -X^1 \\
X & I_E
\end{bmatrix}.
\]

This implies that \(\sigma(\mathcal{H}) = \sigma(Z_\psi) \cup \sigma(Z_\phi)\). Therefore, the eigenvalues of \(Z_\psi\) are exactly the eigenvalues of the Hamiltonian \(\mathcal{H}\).

Proof. Let \(X\) be a bounded solution of (7); \(V\) is assumed to be bounded as well. From the definition of \(Z_\psi\) we have \(D(Z_\psi) = D(H_\psi)\), and thus \(D(\mathcal{H}) = D(\mathcal{H}_d)\). Since \(X\) solves the Riccati equation (7), it is clear that \(HS = SH_d\). To prove \(H \sim \mathcal{H}_d\) we will show that \(S\) is invertible and \(S^{-1}\) is bounded. Indeed, \(S = I + X\), where

\[
X = \begin{bmatrix}
0 & -X^1 \\
X & 0
\end{bmatrix}.
\]

Since \(X^1 = -X\), the spectrum of \(X\) is a subset of the imaginary axis. In particular, \(-1 \notin \sigma(X)\); thus, \(0 \notin \sigma(S)\) and, hence, \(S\) has a bounded inverse. \(\square\)
Remark 3. The stationary states $\rho_\psi$, $\rho^\theta$ indicated in theorem 1 are given by

$$\rho_\psi = A \left( \frac{1}{\langle X_\psi \rangle} \frac{\langle X_\psi \rangle}{\|X_\psi\|^2} \right) \quad \text{and} \quad \rho^\theta = B \left( \frac{\|X^\dagger\phi\|^2 - \langle X_\phi \rangle}{\langle X_\phi \rangle} \right),$$

(12)

where $|\psi\rangle \in D(H_\psi)$ and $|\phi\rangle \in D(H_\phi)$ are normalized eigenvectors of $Z_{-}$ and $Z_{+}$, respectively. $A = \text{Tr}(\rho_\psi)$, $B = \text{Tr}(\rho^\theta)$ are normalization constants and $\langle X_\phi \rangle = \langle \psi | X | \psi \rangle$.

Proof. Since $\text{Tr}[\psi \langle \phi \rangle] = \langle \phi \langle \psi \rangle \rangle$, equations (12) can be obtained directly from definition (3) and formula (4).

4. Examples

4.1. Spin-boson model

In this subsection, we will demonstrate an application of the presented method to a non-trivial example, namely the paradigmatic spin-boson model [29, 30]. Assume that the Hamiltonian of the qubit (spin-half) and its environment (boson) are in the following forms:

$$H_Q = \beta \sigma_z + \alpha \sigma_x \quad \text{and} \quad H_E = \omega a^\dagger a,$$

(13)

respectively. For the sake of simplicity, we consider the case where there is only one boson in the bath. The interaction between the systems reads

$$H_{int} = \sigma_z \otimes (g^* a + g a^\dagger) \equiv \sigma_z \otimes V.$$

(14)

In the above description, $\sigma_x$ and $\sigma_z$ are the standard Pauli matrices and $\alpha, \beta \in \mathbb{R}$. The creation $a^\dagger$ and annihilation $a$ operators obey the canonical commutation relation (CCR) $[a, a^\dagger] = 1$ [1]. Parameters $\omega > 0$ and $g \in \mathbb{C}$ represent the energy of the boson and the coupling constant between the qubit and the boson, respectively.

If $\alpha = 0$ (no energy exchange between the systems), the model can be solved, i.e. the reduced dynamics can be obtained, exactly [31, 32]. The solution describes the physical phenomena known as the pure decoherence or dephasing [33]. On the other hand, when $\alpha \neq 0$ the exact solution in not known. The objective is to estimate the stationary states for the latter case.

To proceed, we must clarify some technical aspects (e.g. domains of $H_\psi$). Clearly, the operators $a$ and $a^\dagger$ cannot both be bounded since the trace of their commutator does not vanish [34]. Therefore, the CCR holds only on some dense subspace $D_2$ of $\mathcal{H}_E$. Let $D_1$ be the dense domain of both $a$ and $a^\dagger$, on which they are mutually adjoint, that is, $(a^\dagger)\dagger = a$ and $a^\dagger = a^\dagger$. At this point, it is not obvious that the sets $D_1, D_2$, having desire properties, exist. The detailed construction can be found in [35] and the right choice is given by

$$D_k = \left\{ |\psi\rangle \in \mathcal{H}_E : \sum_{n=0}^{\infty} n^k |\langle \psi | \phi_n \rangle|^2 < \infty \right\}, \quad k = 1, 2.$$

(15)

On $D_1$ the creation and annihilation operators can be defined explicitly as (see also [36–38])

$$a|\phi\rangle = \sum_{n=1}^{\infty} \sqrt{n} \langle \phi_n | \phi \rangle |\phi_{n-1}\rangle, \quad a^\dagger|\phi\rangle = \sum_{n=0}^{\infty} \sqrt{n+1} \langle \phi_{n+1} | \phi \rangle |\phi_n\rangle, \quad |\phi\rangle \in D_1.$$

(16)

$\{|\phi_n\rangle\}_{n=0}^{\infty}$ is an orthonormal basis in $\mathcal{H}_E$. From (16) it follows that $a^\dagger|\phi_n\rangle = \sqrt{n+1} |\phi_{n+1}\rangle$ and $a|\phi_n\rangle = \sqrt{n} |\phi_{n-1}\rangle$, which in most books on quantum mechanics is a definition of the creation and annihilation operators. However, the operators defined in such a way are not closed; nevertheless, they are closable and their closures are given by (16).
Since $a$ is closed, $H_E$ is a positive self-adjoint operator and $D_2 \subset D_1$ is a core of $a$ (see, e.g., theorem 4.2.1 in \cite{39}). Henceforward, we assume that the basis $\{\phi_n\}_{n=0}^\infty$ is composed with the eigenvectors of $H_E$. In this case we have

$$H_E|\phi\rangle = \sum_{n=0}^\infty \alpha_n \langle \phi_n | \phi \rangle |\phi_n\rangle, \quad |\phi\rangle \in D_2. \quad (17)$$

By choosing a suitable coupling constant $g$, it is possible to make $H_a = H_E \pm V$ self-adjoint on $D_a := D_1 \cap D_2 = D_2$. To see this, let us first note that $(g^*a + ga^*)^* \supset g^*a + ga^*$; thus, $V$ is Hermitian (symmetric). Since $H_E$ is self-adjoint and $V$ Hermitian, it is sufficient to show that $V$ is relatively bounded with respect to $H_E$ ($H_E$-bounded) and has $H_E$-bound less than 1. A fundamental result of perturbation theory, known as the Kato–Rellich theorem \cite{34}, assures self-adjointness of $H_a$ in this case.

Recall that $B$ is $A$-bounded if (i) $D(A) \subset D(B)$ and (ii) $\|B(\phi)\|^2 \leq a\|A(\phi)\|^2 + b\|\phi\|^2$ for all $|\phi\rangle \in D(A)$ and some nonnegative constants $a$, $b$. The infimum of all $a$ for which a corresponding $b$ exists such that the last inequality holds is called the $A$-bound of $B$. Note that sometimes it is convenient to replace the condition (ii) by the equivalent one: $\|B(\phi)\| \leq a\|A(\phi)\| + b\|\phi\|$. \(\Box\)

It is not difficult to see that if two operators $B_1$ and $B_2$ are bounded with respect to the same operator $A$ and their relative bound are less than $b_1$ and $b_2$, respectively, then $a_1B_1 + a_2B_2$ is also $A$-bounded and its relative bounded is less than $|a_1|b_1 + |a_2|b_2$ (see lemma 6.1 in \cite{40}). In other words, the set of all $A$-bounded operators form a linear space. Therefore, to see that $V$ is $H_E$-bounded it is sufficient to prove that both $a$ and $a^1$ are $H_E$-bounded. To finish this, note

$$\|a(\phi)\|^2 = \sum_{n=1}^\infty n|\langle \phi_{n-1} | \phi \rangle|^2 = \sum_{n=0}^\infty (n+1)|\langle \phi_n | \phi \rangle|^2 \leq \sum_{n=0}^\infty n^2|\langle \phi_n | \phi \rangle|^2 + \sum_{n=0}^\infty |\langle \phi_n | \phi \rangle|^2 = \omega^{-1}\|H_E|\phi\|^2 + \|\phi\|^2. \quad (18)$$

In comparable manner one can also verify that $\|a^1(\phi)\|^2 \leq \omega^{-1}\|H_E|\phi\|^2$. Since $H_E$-bound of both $a$ and $a^1$ is less than 1, the $H_E$-bound of $V$ is also less than 1 for $|g| < 1/2$.

The block operator matrix representation of the spin-boson Hamiltonian reads

$$H = \begin{bmatrix} H_a & \alpha \\ \alpha & H \end{bmatrix}, \quad \text{where} \quad H_a = H_E \pm V \quad \text{and} \quad D(H) = D_2 \oplus D_2; \quad (19)$$

the quantity $\alpha$ is understood as $\alpha \|E\|$. For the sake of simplicity we have set $\beta = 0$; the example remains non-trivial because $[H_Q \otimes I_E, H_{\text{int}}] \neq 0$. The corresponding Riccati equation takes the form

$$\alpha X^2 + XH_a - H_aX - \alpha = 0 \quad \text{on} \quad D_2. \quad (20)$$

In order to solve this equation we define an operator $P$ as

$$P|\psi\rangle = \sum_{n=0}^\infty \omega^{\alpha n} \langle \phi_n | \psi \rangle |\phi_n\rangle, \quad |\psi\rangle \in H_E. \quad (21)$$

Directly from (21) we have $P = P^*$ and $P^2 = \|E\|$; thus, $P$ is both self-adjoint and unitary. Formally, $P$ can be written as $P = \exp(i\frac{\alpha}{2}H_E)$; however, unlike $H_E$, $P$ is everywhere defined. The Hellinger–Toeplitz theorem guarantees that $P$ is bounded, which can also be seen directly. Indeed, from unitarity we obtain $\|P|\psi\| = \|\psi\|$, for $|\psi\rangle \in H_E$; hence, $\|P\| = 1$. $P$ is, in fact,
the bosonic parity operator \([41]\). We will show that \(X = P\) solves (20). Since \(P^2 = 1\) it is sufficient to show that
\[
PH_1 - H_1P = 0 \quad \text{or equivalently} \quad PH_1 P = H_1 \quad \text{on} \quad D_2. \tag{22}
\]
In order to prove (22) let us first note that \(P|\psi\rangle \in D_2\) for \(|\psi\rangle \in D_2\), which means \(\text{Ran}(P|D_1) \subset D_2\). This follows from \(|e^{it\sigma} \rangle = 1\). Furthermore, \(PHE P = HE\) and \(PV P = -V\). The first equality is obvious, while the second one follows from \(PaP = -a\) and \(Pa^\dagger P = -a^\dagger\). As a result we obtain (22).

The stationary states in this example can be written as
\[
\rho_\pm = \frac{1}{2} \begin{pmatrix} 1 & r_\pm \\ r_\pm & 1 \end{pmatrix}, \quad \text{where} \quad r_\pm = \pm \langle \psi_\pm | P | \psi_\pm \rangle, \tag{23}
\]
and \(|\psi_\pm\rangle\) are normalized eigenvectors of \(Z = H_1 = \alpha P\). Unfortunately, the solution of this eigenproblem is not known for \(\alpha \neq 0\). However, one can determine certain bounds on \(r_\pm\) using properties of \(P\) and \(\rho_\pm\). First, \(r_\pm\) are real numbers because \(P\) is self-adjoint. From the non-negativity of \(\rho_\pm\) we obtain that \(r_\pm \in [-1, 1]\).

Equation (23) provides an estimate of the stationary state of the qubit immersed in the bosonic bath. This result has been obtained without any approximations. Of course, \(r_\pm\) can be computed approximately with the use of known methods. It is important to stress that to obtain the exact reduced dynamics for the model in question one needs to resolve an eigenvalue problem for \(Z_{\alpha}\).

4.2. Commuting environment

In the second example we consider the Hamiltonian in the following form:
\[
H = \alpha \sigma_x \otimes 1_E + 1_E \otimes H_0 + \sigma_z \otimes H_1, \quad \alpha \neq 0. \tag{24}
\]
Here we assume that the linear operators \(H_0\) and \(H_1\) are bounded and commute. Moreover, we impose restriction to the spectra of \(H_0\) and \(H_1\), i.e. \(\sigma(H_0)\), \(\sigma(H_1)\) are discrete and non-degenerated. The Hamiltonian (24) describes a qubit in contact with an environment and in the presence of the magnetic field \(\mathbf{B} = B\mathbf{e}_z\), where \(B \sim \alpha\). Examples of such systems occur in the literature, e.g. \([42–44]\). The block operator matrix representation of (24) is given by (19) with \(H_+ = H_0 \pm H_1\) and \(D(H) = 1_E \oplus 1_E\). The corresponding Riccati equation reads (20).

Using the fact that \(H_0\) and \(H_1\) commute, so they have a common set of eigenvectors, we write
\[
H_0|\phi_n\rangle = \lambda_n|\phi_n\rangle \quad \text{and} \quad H_1|\phi_n\rangle = \xi_n|\phi_n\rangle, \tag{25}
\]
where \(\lambda_n \in \sigma(H_0), \xi_n \in \sigma(H_1)\) and \(|\phi_n\rangle|\phi_m\rangle = \delta_{nm}\) for \(n, m \in \mathbb{N}\). The Riccati equation has a positive and self-adjoint solution \(X = f(H_1)\), where the function \(f\) is given by
\[
f(x) = \frac{\sqrt{x^2 + a^2} - x}{a} \quad \text{for} \quad x \in \sigma(H_1). \tag{26}
\]
Unlike the spin-boson model, in this case the eigenproblem for \(Z_{\alpha}\) can be readily solved. Indeed, we have
\[
Z_{\alpha}|\phi_n\rangle = [\lambda_n \pm \xi_n f(\xi_n)]|\phi_n\rangle. \tag{27}
\]
According to remark 3 we obtain
\[
\rho_\pm = C_n \left( \frac{1}{f(\xi_n)}, \frac{f(\xi_n)}{|f(\xi_n)|^2} \right) \quad \text{and} \quad \rho_0 = C_n \left( \frac{|f(\xi_n)|^2}{-f(\xi_n)}, 1 \right). \tag{28}
\]
where \(C_n = (1 + |f(\xi_n)|^2)^{-1}\). In this case there are no initial correlations between the systems because \(X|\phi_n\rangle \sim |\phi_n\rangle\). We wish to emphasize that there may exist other solutions of the Riccati equation. For an explicit example see [21].
4.3. Sylvester equation

In the case $V = 0$, the Hamiltonian (2) is already in a block diagonal form. One can note that the Riccati equation simplifies to the Sylvester equation:

$$X H_0 - H_0 X = 0 \quad \text{on} \quad D(H_0). \quad (29)$$

There exists at least one solution, namely $X = 0$. The corresponding stationary states are given by the projections $P_0 = \text{diag}(0, 1) = |0\rangle\langle 0|$ and $P_1 = \text{diag}(1, 0) = |1\rangle\langle 1|$.

4.4. All unbounded entries

In the last example, we consider an interesting example in which all the entries of $H$ are unbounded, but still the solution of the Riccati equation exists as a bounded operator. To see this, let us choose $H_0 = H_0$ with the domain $D(H_0)$ and let us assume that $V$ is self-adjoint with the domain $D(V)$. Then, the Riccati equation

$$XVX + XH_0 - H_0 X - V = 0 \quad \text{on} \quad D(H_0) \cap D(V) \quad (30)$$

has at least two bounded solutions, $X_s = \pm 1$. The stationary states read

$$\rho_s = \frac{1}{2} \begin{pmatrix} 1 & \pm 1 \\ \pm 1 & 1 \end{pmatrix}. \quad (31)$$

An example in which all the entries of a block operator matrix are bounded and the solution of the Riccati equation is unbounded has been provided in [15].

5. Summary

In this paper we have proposed a method of calculating the stationary states for two-level open quantum systems. We have used the theory of block operator matrices; in particular, we have related the solution of the algebraic Riccati equation to stationary states. In the presented method, the stationary states are generated from the stationary states of the total system by tracing out the environment. Our investigation includes the case when the initial system–environment correlations occur. In fact, this case is embedded in the method since the eigenstates of the total Hamiltonian are entanglement.

Finally, we want to stress that the method cannot be used when the total Hamiltonian is not known. Such a situation arises, e.g., when the details of the interaction between the systems are not accessible. We hope that despite aforementioned weaknesses, the results of the paper may serve as a starting point for further investigations.

Acknowledgments

The authors are deeply grateful to the referee for very careful reading of the original manuscript and valuable suggestions. BG would like to thank Jerzy Dajka for his suggestions and comments. This work was financed from the Polish science budget resources in the years 2010–2013 as a research projects: grant no N N519 442339 and project no IP 2010 0334 70.
