The P2 experiment aims at high-precision measurements of the parity-violating asymmetry in elastic electron-proton and electron-$^{12}$C scatterings with longitudinally polarized electrons. We discuss here the sensitivity of P2 to leptoquarks, which within the P2 energy range can be described in the language of Standard Model Effective Field Theory (SMEFT). We give the expected P2 limits on the SMEFT operators and on the leptoquark parameters, which will test energy scales up to 15 TeV. In many cases those limits exceed current constraints from LHC and atomic parity violation (APV) experiments. We also demonstrate that degeneracies of different SMEFT operators can partially be resolved by use of APV experiments and different targets (protons and $^{12}$C) at P2. Moreover, we show that P2 could confirm or resolve potential tensions between the theoretical and experimental determinations of the weak charge of $^{133}$Cs.

I. INTRODUCTION

Leptoquarks are colored scalar or vector particles that couple to the quarks and leptons of the Standard Model (SM), see Ref. [1] for a review. They arise in many theories beyond the SM, including Grand Unified Theories [2–9], string and M-theories [10], R-parity-violating supersymmetry [11] and radiative neutrino mass models [12–16]. They are frequently used candidates to explain the current anomalies in the muon anomalous magnetic moment and in semileptonic $B$-decays [17–65]; see Ref. [66] for a review. In general, the quantum numbers of leptoquarks are governed by the quantum numbers of SM particles involved [67]. As the SM is a chiral theory, hence violates parity, leptoquarks can be expected to influence measurable parity violation. Moreover generally, parity-violating interactions at low-energy scales from new physics at large mass scales can be described by operators of SM Effective Field Theory (SMEFT) [68, 69].

In this paper we focus on the P2 experiment, which will measure the parity-asymmetry in elastic electron-proton or electron-$^{12}$C scatterings at the upcoming Mainz Energy-recovering Superconducting Accelerator (MESA) facility [70]. The crucial observable is the parity violating cross section asymmetry $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$ for the scattering of longitudinally polarized electrons off the targets. The expectation is that the SM parity asymmetry can be measured with 1.4% (0.3%) relative uncertainty for a proton ($^{12}$C) target, which can be used to constrain beyond SM contributions [70, 71]. Our goal in this paper is to use these expected values to set prospective limits on SMEFT coefficients and leptoquark masses and couplings to first-generation SM fermions.

As the momentum exchange relevant for P2 is less than 100 MeV [70] which is very small compared to the allowed mass of leptoquarks, one can approximate their interactions in terms of effective SMEFT operators. Hence, we start by obtaining the prospective limits on relevant SMEFT operators in Table III and Table IV, which can be translated into constraints on specific models inducing these operators, as shown in Table V. Subsequently, we use the identification with SMEFT operators to map out expected bounds on leptoquark parameters. We confront those leptoquark bounds with current constraints, most notably from atomic parity violation (APV) using $^{133}$Cs [72] and from leptoquark production at the LHC in the pair-production [73, 74], Drell-Yan [75] and single resonant production [76] channels. As we will show in Figures 1 and 2, in many cases the P2 limits will supersede current constraints, if the mass of the leptoquark exceeds roughly 2 TeV. We also confirm that certain SMEFT operators lead to an indistinguishable effect in a given observable. In this case one can partially resolve this degeneracy by taking advantage of the fact that different observables use different amounts of up- and down-quarks in the target material, as illustrated in Figure 3. We therefore stress the complementarity of using protons and $^{12}$C at P2, as well as $^{133}$Cs in APV to better disentangle up- and down-quark interactions.

We note that there have been a number of studies on low-energy parity violating effects of new physics [77–84] and in particular on the P2 sensitivity to new physics [71, 85]. While Ref. [71] focuses on low-mass
gauge bosons and Ref. [85] considers broadly a variety of constraints from low-energy observables to collider searches, this work presents a dedicated study on the \( \Lambda \) to apply SMEFT, with an application to the leptoquark scenario. Our main new observation is the importance of using \( ^{12}\text{C} \) target to break the degeneracy between up- and down-quark couplings.

The rest of the paper is organized as follows. In Section II we lay out the formalism of SMEFT operators and leptoquarks with focus on parity violation in the first generation. In Section III we map the fundamental quark-level couplings to nucleon and nucleus couplings, calculate the parity asymmetry and set limits on SMEFT energy scales and leptoquark masses. Section IV compares those limits to current ones from APV and LHC. The advantage of using different targets is illustrated in Section V by taking two effective couplings at a time. Our conclusions are presented in Section A. The parametrization of the form factors is presented in Section B.

II. HIGH-ENERGY ORIGINS OF PARITY VIOLATION IN ELECTRON-HADRON SCATTERING

New physics at large mass scales may lead to deviations from the expected parity violation at scattering experiments. In this section, we describe two frequently investigated scenarios of new physics. The first is the model-independent approach of parametrizing new physics as effective operators in the SMEFT. The second approach is considering minimal scenarios of leptoquarks as explicit particle extensions of the SM.

A. Standard Model Effective Field Theory

If one considers new physics at some high mass scale \( \Lambda \gg m_W \), a suitable framework to encode different possible effects at energies well below that scale is given by effective field theories. For the SM it is convenient to apply SMEFT [86]. Besides the SM Lagrangian, this effective theory consists of a series of non-renormalizable operators of higher mass-dimension \( d \geq 5 \), such that we can write

\[
\mathcal{L}_{\text{eff}} = \mathcal{L}_{\text{SM}} + \sum_i \sum_{n \geq 5} \frac{1}{\Lambda^{n-4}} C_i \mathcal{O}_i^{(n)},
\]

where \( C_i \) denotes the dimensionless Wilson coefficient of the operator \( \mathcal{O}_i \) defined e.g. in Refs. [68, 69]. Operators of dimension \( 4 + n \) are suppressed by respective factors of \( \Lambda^{-n} \). This expansion is supposed to be applicable at interaction energies \( q^2 \ll \Lambda^2 \), while new particles associated with \( \Lambda \) may only be produced on-shell at much higher energy scales.

The SMEFT operators of lowest dimension giving rise to \( eeuu \) or \( eedd \) interactions relevant at the P2 experiment are, in the usual terminology [69], the parity-violating operators\(^{1}\) \( \mathcal{O}_{\text{lequ}(1)} \), \( \mathcal{O}_{\text{lequ}(3)} \), \( \mathcal{O}_{\text{lu}} \), \( \mathcal{O}_{\text{ld}} \), \( \mathcal{O}_{\text{qe}} \), \( \mathcal{O}_{\text{eu}} \), \( \mathcal{O}_{\text{ed}} \), and the parity-conserving operators \( \mathcal{O}_{\text{ledq}} \), \( \mathcal{O}_{\text{lequ}(1)} \), and \( \mathcal{O}_{\text{lequ}(3)} \). Starting with the parity-violating operators the effective Lagrangian can be written as

\[
\mathcal{L}_{\text{PV}} = \frac{1}{\Lambda^2} \sum_{f=u,d} \sum_{X=L,R} \left( \bar{\epsilon} \gamma_{\mu} P_X \epsilon \right) \left[ C_{XVf}(\ell_1^\mu f) + C_{XAf}(\ell_1^{\mu \gamma_5} f) \right],
\]

where \( e, u, \) and \( d \) denote electron, up quark and down quark mass eigenstates. The chirality projectors are given by \( P_{L,R} = \frac{1}{2}(1 \mp \gamma_5) \). The coefficients \( C_{XVf} \) are related to the coefficients of SMEFT operators in the mass basis via

\[
\begin{align*}
C_{LVu} &= \frac{1}{2}(C_{\text{lequ}(1)} - C_{\text{lequ}(3)} + C_{\text{lu}}), \\
C_{LVd} &= \frac{1}{2}(C_{\text{lequ}(1)} + C_{\text{lequ}(3)} + C_{\text{ld}}), \\
C_{LAu} &= \frac{1}{2}(-C_{\text{lequ}(1)} + C_{\text{lequ}(3)} + C_{\text{lu}}), \\
C_{LAd} &= \frac{1}{2}(-C_{\text{lequ}(1)} - C_{\text{lequ}(3)} + C_{\text{ld}}), \\
C_{RVu} &= \frac{1}{2}(C_{\text{qe}} + C_{\text{eu}}), \\
C_{RVd} &= \frac{1}{2}(C_{\text{qe}} + C_{\text{ed}}), \\
C_{RAu} &= \frac{1}{2}(-C_{\text{qe}} + C_{\text{eu}}), \\
C_{RAD} &= \frac{1}{2}(-C_{\text{qe}} + C_{\text{ed}}),
\end{align*}
\]

where first-generation indices \( ee11 \) are implied. For a mapping to the flavor basis, see Section A. The parity-conserving scalar and tensor interactions read

\[
\mathcal{L}_{\text{PC}} = \frac{1}{\Lambda^2} \sum_{f=u,d} \left( \bar{\epsilon} P_L \epsilon \right) \left[ C_{SF}(\ell_1^\mu f) + C_{PF}(\ell_1^{\mu \gamma_5} f) \right] + \text{H.c.},
\]

with the mass-basis coefficients

\[
\begin{align*}
C_{Su} &= C_{Pu} = -\frac{1}{2} C_{\text{lequ}(1)}, \\
C_{Sd} &= C_{Pd} = \frac{1}{2} C_{\text{ledq}}, \\
C_{Tu} &= -C_{\text{lequ}(3)}, \\
C_{Td} &= 0.
\end{align*}
\]

We have checked that these definitions are consistent with previous investigations of parity violation from

\(^{1}\) Other works on the parity-violating operators can be found e.g. in Refs. [87, 88].
SMEFT [88]. Since (pseudo)scalar and tensor interactions are parity-conserving, the P2 sensitivity of these interactions is poor compared to other probes. For this reason we focus on the parity-violating vector and axial vector interactions.

### B. Leptoquarks

Leptoquarks are hypothetical scalar or vector particles which generically contribute to parity-violating interactions. In this work we follow the naming convention of Ref. [67] and consider all leptoquarks which can give rise to effective quark-electron interactions. In this work we follow the naming convention of Ref. [67] and consider all leptoquarks which can give rise to effective quark-electron interactions.

These are listed, along with their quantum numbers, in Table I. For convenience, we write all of them as fundamental representations of SU(3)$_C$.

The contributions to the parity-violating SMEFT operators from integrating out heavy leptoids read

\[
C_{LQ(1)} = \frac{1}{4} |s_1 L|^2 - \frac{3}{4} |s_3 L|^2 + \frac{1}{2} |u_1 L|^2 + \frac{3}{2} |u_3 L|^2, \quad (6a)
\]

\[
C_{LQ(3)} = \frac{1}{4} |s_1 L|^2 - \frac{1}{4} |s_3 L|^2 + \frac{1}{2} |u_1 L|^2 - \frac{1}{2} |u_3 L|^2, \quad (6b)
\]

\[
C_{eu} = -\frac{1}{2} |s_1 R|^2 + |\bar{u}_1|^2, \quad (6c)
\]

\[
C_{ed} = -\frac{1}{2} |\bar{s}_1|^2 + |u_1 R|^2, \quad (6d)
\]

\[
C_{qe} = \frac{1}{2} |r_2 L|^2 - |v_2 R|^2, \quad (6e)
\]

\[
C_{lu} = \frac{1}{2} |r_2 L|^2 - |\bar{v}_2|^2, \quad (6f)
\]

\[
C_{ld} = \frac{1}{2} |\bar{r}_2|^2 - |v_2 L|^2, \quad (6g)
\]

where we have identified \( \Lambda = m_{LQ} \) (the same for all leptoquarks). The couplings are defined through the interaction Lagrangians

\[
\mathcal{L}_{F=2} = (s_{1L} \bar{q}^{a} e^{ab}(l^{c})^{b} + s_{1R} \bar{w} e^{c}) S_{1} + s_{1R} \bar{e}^{c} S_{1} + s_{3} \bar{q}^{a} (\bar{\tau})^{ab} (l^{c})^{d} \bar{S}_{3} + (v_{2R} \bar{q}^{a} \gamma_{\mu} e^{b} + v_{2L} \bar{\tau} \gamma_{\mu} (l^{c})^{a} V_{\mu}^{a}) + \bar{v}_{2} \bar{w} \gamma_{\mu} (l^{c})^{a} \bar{V}_{\mu}^{a} + \text{H.c.}, \quad (7a)
\]

\[
\mathcal{L}_{F=0} = (r_{2L} \bar{q}^{ab} e^{c} R_{2}^{a}) R_{2}^{b} + (\bar{r}_{2L} \bar{w} e^{c} R_{2}^{a}) R_{2}^{b} + (u_{1L} \bar{q}^{a} l + u_{1R} \bar{d} \gamma_{\mu} e^{c} R_{2}^{a} U_{\mu}^{a} + \bar{u}_{1} \bar{w} \gamma_{\mu} e^{c} U_{\mu}^{a} + \text{H.c.}, \quad (7b)
\]

where \( a, b \) denote SU(2)$_C$ indices, \( e^{ab} \) is the Levi-Civita symbol, and \( \bar{\tau} = (\tau_{1}, \tau_{2}, \tau_{3}) \) are the Pauli matrices. Generally, we refer to any single mass by \( m_{LQ} \) and any single coupling by \( g_{LQ} \).

Collider searches have ruled out leptoquarks of masses below about 1.8 TeV, as discussed in Section IV B.

### III. SETTING CONSTRAINTS

#### A. Mapping fundamental couplings to nucleon and nucleus couplings

In order to connect the fundamental couplings with quarks to those with protons or, more generally, with nuclei, we need to apply the nuclear matrix elements and introduce form factors. Following the usual convention explained e.g. in Ref. [89], we write for the vector and axial-vector currents

\[
\langle N(p')|\bar{f}\gamma^{\mu} f|N(p)\rangle = \bar{u}(p') \left[ F^{N}_{1}(q^{2}) g_{\mu}^{\nu} \frac{2m_{N}}{m_{N}} \right] u(p), \quad (9a)
\]

\[
\langle N(p')|\bar{f}\gamma^{\mu}\gamma^{5} f|N(p)\rangle = \bar{u}(p') \left[ G^{N}_{A}(q^{2}) g_{\mu}^{\nu} + G^{N}_{P}(q^{2}) \frac{2m_{N}}{m_{N}} \right] u(p), \quad (9b)
\]

where \( q = p_{e} - k_{e} \) is the difference of initial and final state electron momenta, \( f = u, d, s \) (note that we include \( s \) quarks) and \( N = p, n \) for nucleons. Assuming isospin symmetry, the form factors related to the vector matrix element can be related to the electromagnetic Dirac and
Pauli form factors $F_{i}^{N}$ and $F_{i}^{\mu}$ as

$$F_{i}^{u,p} = F_{i}^{d,n} = 2F_{i}^{\mu} + F_{i}^{n} + F_{i}^{s,p}, \quad (10a)$$
$$F_{i}^{d,p} = F_{i}^{u,n} = 2F_{i}^{\mu} + F_{i}^{n} + F_{i}^{s,p}. \quad (10b)$$

The form factors $F_{i}^{N}$ can be rewritten in terms of the electric and magnetic Sachs form factors $G_{E}$ and $G_{M}$ as

$$F_{1}^{N}(q^{2}) = \frac{G_{E}^{N}(q^{2}) - \frac{q^{2}}{4m_{N}^{2}}G_{M}^{N}(q^{2})}{1 - q^{2}/4m_{N}^{2}}, \quad (11a)$$
$$F_{2}^{N}(q^{2}) = \frac{G_{M}^{N}(q^{2}) - G_{E}^{N}(q^{2})}{1 - q^{2}/4m_{N}^{2}}. \quad (11b)$$

The same holds true for the strange form factors $F_{1}^{s,p}$ which can be expressed in terms of Sachs form factors $G_{E}^{s}$ and $G_{M}^{s}$ analogous to Eq. (11). We use the same parametrization of the form factors as Ref. [70]. Details are given in Section B. Turning to the axial form factors, we take [89]

$$G_{A}^{N} = \Delta_{q}^{(N)}, \quad (12a)$$
$$G_{T}^{N} = -4m_{N}^{2} \left( \frac{a_{u,\pi}^{N}}{q^{2} - m_{n}^{2}} + \frac{a_{u,\eta}^{N}}{q^{2} - m_{\eta}^{2}} \right), \quad (12b)$$

where

$$a_{u,\pi}^{N} = a_{d,\pi}^{N} = \frac{1}{2}g_{A}^{N},$$
$$a_{u,\pi}^{N} = a_{d,\pi}^{N} = 0,$$
$$a_{u,\eta}^{N} = a_{d,\eta}^{N} = \frac{1}{2}a_{s,\eta}^{N} = \frac{1}{6}g_{A}^{s},$$

with

$$g_{A}^{N} = \Delta_{u}^{N} - \Delta_{d}^{N},$$
$$g_{A}^{s} = \Delta_{u}^{s} + \Delta_{d}^{s} - 2\Delta_{p}^{s}.$$ 

Isospin symmetry implies $a_{u,\pi}^{N} = a_{d,\pi}^{N}$ and $a_{u,\pi}^{N} = a_{d,\pi}^{N}$. We use the values $\Delta_{u}^{N} = 0.842$, $\Delta_{d}^{N} = -0.427$, $\Delta_{u}^{N} = -0.085$ [90] and neglect further dependencies on momentum transfer.

In the case of nuclei $\mathcal{N}$ instead of a nucleon, we express the nuclear matrix elements in the same way as in Eqs. (9) with nuclear form factors $F_{i}^{f,\mathcal{N}}(q^{2})$, $G_{i}^{f,\mathcal{N}}(q^{2})$, i.e.

$$\langle \mathcal{N}'(p')|\mathcal{T}_{\gamma}^{\mu\nu}f|\mathcal{N}(p)\rangle = \pi(p') \left[ F_{1}^{f,\mathcal{N}}(q^{2})\gamma^{\mu}\gamma^{\nu} + F_{2}^{f,\mathcal{N}}(q^{2})\gamma^{5}\frac{i\sigma^{\mu\nu}q_{\nu}}{2m_{\mathcal{N}}} \right] u(p), \quad (13a)$$
$$\langle \mathcal{N}'(p')|\mathcal{T}_{\gamma}^{\mu\nu}\gamma^{5}f|\mathcal{N}(p)\rangle = \pi(p') \left[ G_{1}^{f,\mathcal{N}}(q^{2})\gamma^{\mu}\gamma^{5} + G_{2}^{f,\mathcal{N}}(q^{2})\gamma^{5}\gamma^{5} \frac{i\sigma^{\mu\nu}q_{\nu}}{2m_{\mathcal{N}}} \right] u(p). \quad (13b)$$

For simplicity, in this work we consider the $q^{2} = 0$ approximation of the form factors and nuclear matrix elements of nuclei, namely $F_{1}^{f,\mathcal{N}}$, are obtained from up- and down-quark form factors in the same way as for the nucleons in Eq. (10). As we show below, the effect of axial couplings is strongly suppressed in the parity asymmetry parameter and nuclear weak charge. Therefore, in summary, we only use the $F_{1}$ form factors when considering nuclei $^{12}$C and $^{133}$Cs, which gives the dominating contribution.

### B. Asymmetry parameter

Concentrating on the electron-nucleus cross section induced by $\mathcal{L}_{PV}$ in Eq. (2) together with SM physics, i.e. photon and Z boson exchange, we note that the amplitudes for left-handed or right-handed incoming electrons can be written as

$$i\mathcal{M}_{L,R}^{\pm,s',r'} = \sum_{j=1}^{8} K_{j} \left( \pi_{s'}(k_{s})O_{j}u_{\pm}(p_{e}) \right) \times \left( \pi_{r'}(k_{r})O_{j}^{*}u_{s}(p_{p}) \right). \quad (14)$$

where $K_{j}$, $O_{j}$, and $O_{j}^{*}$ are given in Table II for the general case. In this calculation we equate helicity and chirality of the incoming electron in order to replace $u_{\pm}(p_{e})$ by $P_{R/L}u_{s}(p_{e})$ and using trace identities from summing over $s$. The correction to the amplitude due to this approximation should be of order $m_{e}/|p_{e}| \approx 0.5\text{MeV}/155\text{MeV} \approx 3 \times 10^{-3}$ and is negligible for our purposes.

The differential cross section for initial polarization $X$ is proportional to the squared matrix element,

$$\frac{d\sigma_{X}}{dt} \sim |\mathcal{M}_{X}|^{2}, \quad (15)$$

($t$ being the Mandelstam variable) and therefore the asymmetry parameter is simply given by the squared amplitudes in the form of

$$A_{PV} = \frac{d\sigma_{+} - d\sigma_{-}}{d\sigma_{+} + d\sigma_{-}} = \frac{|\mathcal{M}_{R}|^{2} - |\mathcal{M}_{L}|^{2}}{|\mathcal{M}_{R}|^{2} + |\mathcal{M}_{L}|^{2}}. \quad (16)$$

### TABLE II. Coefficients appearing in the amplitude of chiral electron-proton scattering Eq. (17).

| $j$ | $K_{j}$ | $O_{j}$ | $O_{j}^{*}$ |
|-----|---------|--------|------------|
| 1   | $C_{LVu}F_{1}^{u,N}$ | $C_{LVd}F_{1}^{d,N}$ | $\gamma_{u}P_{L}$ |
| 2   | $C_{LVu}F_{2}^{u,N}$ | $C_{LVd}F_{2}^{d,N}$ | $\gamma_{v}P_{L}$ |
| 3   | $C_{RVu}F_{1}^{u,N}$ | $C_{RVd}F_{1}^{d,N}$ | $\gamma_{u}P_{R}$ |
| 4   | $C_{RVu}F_{2}^{u,N}$ | $C_{RVd}F_{2}^{d,N}$ | $\gamma_{v}P_{R}$ |
| 5   | $C_{LSu}F_{1}^{u,N}$ | $C_{LSd}F_{1}^{d,N}$ | $\gamma_{u}P_{L}$ |
| 6   | $C_{LSu}F_{2}^{u,N}$ | $C_{LSd}F_{2}^{d,N}$ | $\gamma_{v}P_{R}$ |
| 7   | $C_{RaLu}F_{1}^{u,N}$ | $C_{RaRd}F_{1}^{d,N}$ | $\gamma_{u}P_{L}$ |
| 8   | $C_{RaLu}F_{2}^{u,N}$ | $C_{RaRd}F_{2}^{d,N}$ | $\gamma_{v}P_{R}$ |
where

\[
|\mathcal{M}_{L,R}|^2 = \frac{1}{2} \sum_{j,k=1}^{8} \sum_{s,s',r,r'=\pm} \frac{1}{\Lambda^2} K_j K_k \times \sum_{s,s',r,r'=\pm} \text{tr}\left[ (\hat{k}_e + m_e) \mathcal{O}_j P_{L,R}(\hat{p}_e + m_e) P_{L,R} \gamma^0 \mathcal{O}^{(\hat{k}_e + m_e) \gamma^0} \right] \times \text{tr}\left[ (\hat{k}_N + m_N) \mathcal{O}^{(\hat{p}_N + m_N) \gamma^0} \right].
\]

(17)

To account also for the SM contributions of photon and Z boson exchange in the calculation we replace in Table II

\[
\begin{align}
\frac{C_{XVf}}{\lambda^2} &= -\frac{4\pi a_{f}}{q^2} + \frac{g^2}{2\sqrt{2}} g^{u}_{f} g^{v}_{f} + \frac{C_{XVf}}{\lambda^2}, \quad (18a) \\
\frac{C_{XAf}}{\lambda^2} &= \frac{g^2}{2\sqrt{2}} g^{u}_{f} g^{v}_{f} + \frac{C_{XAf}}{\lambda^2}, \quad (18b)
\end{align}
\]

where the SM charges and couplings are, as usual, \( g^2 = \frac{4\pi\alpha}{s_W^2} \) (with \( s_W^2 = \sin^2 \theta_W \) being the sine of the weak mixing angle, and \( \alpha = e^2/4\pi \) being the fine-structure constant), and

\[
\begin{align}
q_u &= \frac{2}{3}, & q_d &= \frac{1}{3}, \\
g^u &= \frac{-4}{3} s_W^2, & g^d &= \frac{-2}{3}, \\
g^d &= \frac{-2}{3} s_W^2, & g^d &= \frac{-2}{3}. 
\end{align}
\]

(19)

The full resulting expression is too lengthy to reproduce here. It is, however, illustrative to re-derive certain limits from it. To recover the leading-order SM expectation for the case of a proton, we can set all \( C \) coefficients to zero such that the term of leading order in \( q^2/m_W^2 \) reads

\[
A_{PV}^{LO} = \frac{g^2}{2\sqrt{2}} \frac{(g^R_R - g^L^\gamma_\rho)(F^{u,p}_q(q^2)g^u_g^v + F^{d,p}_q(q^2)g^d_g^v)}{4\pi\alpha(F^{u,p}_q q_u + F^{d,p}_q q_d) m_W^2}. \quad (20)
\]

Taking \( F^{u,p}_1(q^2) \approx F^{u,p}_q(0) = 2 \) and \( F^{d,p}_1(q^2) \approx F^{d,p}_q(0) = 1 \) we obtain the standard result [70]

\[
A_{PV}^{LO} = -\frac{g^2}{2\sqrt{2}} \frac{(g^R_R - g^L^\gamma_\rho)(2g^u_g^v + g^d_g^v)}{4\pi\alpha(4/3 - 1/3)} \frac{Q^2}{1-4s_W^2} , \quad (21)
\]

where \( Q^2 = -q^2 \). We observe that (weak) axial charges do not contribute at leading order in the proton case. Evaluating this expression at the central value for the scattering angle in P2, \( q^2 = -93 \text{MeV}^2 \), and for the expected low-energy value of the Weinberg angle, \( s_W^2 = 0.23 \), results in \( A_{PV}^{LO} = -4.815 \times 10^{-8} \) for the proton. This deviates from the SM expectation \( A_{PV}^{SM} = -3.994 \times 10^{-8} \) due to radiative corrections [70]. Instead of accounting for all corrections, we will consider the relative strength of deviations from the expected asymmetry due to new physics contributions \( A_{PV}^{NP} \), that is, we consider \( \Delta A_{PV}^{NP}/A_{PV}^{SM} \) as detailed below. Before doing that, we state the leading-order asymmetry in the case of \(^{12}\text{C}\). In this case we have, approximately, \( F^{u,c}_{1}\approx 6n_{u,p} + 6n_{u,n} = 18 \) and \( F^{d,c}_{1}\approx 6n_{d,p} + 6n_{d,n} = 18 \), where \( n_{f,N} \) denotes the number of valence quarks \( f \) contained in the nucleon \( N \), such that

\[
A_{PV}^{LO} = \frac{g^2}{2\sqrt{2}} \frac{(g^R_R - g^L_\rho)(18g^u_g^v + 18g^d_g^v)}{4\pi\alpha(4/3 - 1/3)} = \frac{G_F}{2} \frac{Q^2}{\sqrt{2} 4\pi \alpha} 4s_W^2. \quad (22)
\]

We have examined possible uncertainties on the theoretical predictions for \( A_{PV} \) and identified that the largest uncertainty arises from the form factors. The various form factors used in the calculation are generally \( q^2 \) dependent. The weak interaction contribution relies on the weak charge form factor

\[
F_Z(q^2) = F_1^{u,p}(q^2)g^u_g^v + F_1^{d,p}(q^2)g^d_g^v \quad (23)
\]

(for leptoquark and other new physics, one has different combinations of \( F_1^{u,p} \) and \( F_1^{d,p} \)) which differs from the electric charge form factor

\[
F_\gamma(q^2) = F_1^{u,p}(q^2)q_u + F_1^{d,p}(q^2)q_d. \quad (24)
\]

When \( q^2 \) is not negligibly small, the \( q^2 \) dependence of these form factors corrects the results as

\[
A_{PV} \rightarrow A_{PV} = \frac{F_Z(q^2)}{F_\gamma(q^2)} F_\gamma(0) = \frac{F_Z(q^2)}{F_\gamma(q^2)}. \quad (25)
\]

A simple approach to estimate the correction is to make use of

\[
R_{Z/\gamma}^2 = \frac{6}{F_Z/\gamma(0)} \frac{|dF_Z(q^2)/dq^2|}{|q^2| \rightarrow 0},
\]

which is the weak/electric charge radius of proton. Using experimentally determined values \( R_{\gamma} \approx 0.84 \text{ fm} \) and \( R_Z \approx 1.55 \text{ fm} \) [91], we obtain \( F_\gamma(q^2)/F_\gamma(0) \approx 1 - 0.026 \) and \( F_Z(q^2)/F_Z(0) \approx 1 - 0.089 \) for \( q^2 = -93 \text{ MeV}^2 \), and hence \( A_{PV} \rightarrow (1 - 0.063)A_{PV} \), which implies that including the \( q^2 \) dependence of form factors leads to a 6.3% smaller value of \( A_{PV} \) in the SM. As for new physics predictions, the results generally depend on different combinations of \( F_1^{u,p}(q^2) \) and \( F_1^{d,p}(q^2) \), and hence different form factors. The uncertainty according to the above analysis is expected to be at the percent level as well. For \(^{12}\text{C}\), the correction is also at the percent level according to the Helmholtz analytic approximation for nuclear form factors [92].

C. SMFET operators

Let us now consider single-operator extensions of the SM. We have to carefully expand the contributions in terms of small parameters in order to extract the correct leading contribution of a given operator. We can broadly
classify the energy scales involved into small scales, $m_e$, $m_p$, $E_e$, $q^2$, and large scales $m_Z$ and $\Lambda$. Without new physics, the results can generally be expanded in inverse powers of $m_Z$. In the presence of new physics parametrized by $C/\Lambda^2$, we can make a double expansion in powers $m_Z^{-2n}$ and $\Lambda^{-2n}$. The leading new-physics contribution, if present, should be of order $\Lambda^{-2}$. We find the following leading new-physics contributions

$$\Delta A_{PV}^{LV}(N) \approx \frac{C_{LV}}{\Lambda^2} \frac{q^2}{4\pi\alpha} \frac{F_{1N}^{u}}{q_u F_{1u}^{uN} + q_d F_{1d}^{uN}},$$

(26a)

$$\Delta A_{PV}^{RV}(N) \approx -\frac{C_{RV}}{\Lambda^2} \frac{q^2}{4\pi\alpha} \frac{F_{1N}^{l}}{q_u F_{1u}^{lN} + q_d F_{1d}^{lN}},$$

(26b)

$$\Delta A_{PV}^{LA}(N) \approx \frac{C_{LA}}{\Lambda^2} \frac{E_e q^4}{4\pi\alpha(2E_e^2 - m_e^2)m_N} \times \frac{q_u(F_{1u}^{uN} + F_{1d}^{uN}) + q_d(F_{1d}^{uN} + F_{1d}^{dN})}{(q_u F_{1u}^{uN} + q_d F_{1d}^{uN})^2},$$

(26c)

$$\Delta A_{PV}^{RA}(N) \approx \frac{C_{RA}}{\Lambda^2} \frac{E_e q^4}{4\pi\alpha(2E_e^2 - m_e^2)m_N} \times \frac{q_u(F_{1u}^{uN} + F_{1d}^{uN}) + q_d(F_{1d}^{uN} + F_{1d}^{dN})}{(q_u F_{1u}^{uN} + q_d F_{1d}^{uN})^2},$$

(26d)

where $f = u, d$. This also shows that the sensitivity on axial interactions is lower due to the additional suppression by $q^2/(m_N E_e)$. One can check numerically for proton and $^{12}$C that these are indeed the leading contributions to the correction to the asymmetry. However, we will use the exact expressions for our numerical results. It is not surprising that no power of $m_Z^{-2}$ is required here, because these four operators are by themselves parity-violating. The (pseudo)scalar and tensor operators, being parity-conserving, would require a cross-term with the SM-intrinsic parity violation expressed through the $Z$-couplings in order to contribute to $\Delta A_{PV}$. Therefore the sensitivity of P2 to those interactions is very weak. This justifies again our separation into parity-violating interactions in Eq. (2) and parity-conserving interactions in Eq. (4).

The sensitivity of P2 to new physics can be estimated by the same method as in Ref. [71]. Namely, we require that the new physics contribution does not exceed

$$\frac{\Delta A_{PV}}{A_{PV}} = \begin{cases} \sqrt{3.84} \times 1.4\% = 2.74\% & N = p,\\ \sqrt{3.84} \times 0.3\% = 0.59\% & N = ^{12}C, \end{cases},$$

(27)

which corresponds to 95% CL. These numbers correspond to the expected sensitivities of the P2 experiment according to Ref. [70]. For the normalization in the case of protons, we use the expected SM value $A_{PV}^{\text{SM}} = -3.994 \times 10^{-5}$. For the normalization in the case of $^{12}$C, we use the leading-order SM result from our own calculation. Moreover, we approximate $F_{1u,^{12}C} = F_{1L}^{^{12}C} = 18$ while neglecting the other form factors. This

| Target | $C/\sqrt{C}$ [TeV] | $C/\sqrt{C}$ [TeV] |
|--------|------------------|------------------|
| $C_{LV\nu}$ | 13.1 | 13.1 |
| $C_{LVd}$ | 9.3 | 9.3 |
| $C_{RV\nu}$ | 2.6 | 2.6 |
| $C_{RVd}$ | 1.8 | 1.8 |

TABLE IV. Expected bounds at 95% CL on the scale $\Lambda/\sqrt{C}$ of SMEFT operators from P2 for the case of proton and carbon targets, assuming a single coupling at a time. These are compared to bounds from APV [72] in Section IV A and ATLAS dilepton searches discussed in Section IV.

D. Leptoquarks

As obvious from Eqs. (6a)-(6g), the same SMEFT operator is generated by different leptoquarks. If we assume one coupling to dominate, we can constrain $m_{LQ}/g_{LQ}$ in the EFT-like limit of $m_{LQ} \gg q^2$. To achieve this, one can take the expression for the asymmetry in terms of the coefficients in Eq. (3a) and then use the matching of leptoquark couplings to SMEFT operators in Eqs. (6a)-(6g). The results are shown in Table V as
well as Figures 1-2. Since for $^{12}$C we are neglecting momentum dependence of the form factors as well as the contributions of leptoquarks to axial currents (which are suppressed, as discussed below Eq. (26d)), those numbers represent the leading order with respect to form factor and momentum-dependent corrections. They are, however, sufficient to compare sensitivities of different targets to different interactions.

We observe that generically the bounds using the proton target are stronger than the ones using $^{12}$C. This can be explained by the smaller $A_{1}^{LO}$ of the proton, which is proportional to $(1 - 4s_W^2) \approx 0.08$ compared to $(4s_W^2) \approx 0.92$ for $^{12}$C. Considering that $\Delta A_{PV}$ in Eqs. (26a) and (26b) for up quarks and down quarks differs only by the factors

$$ \frac{F_{1}^{l-p}}{q_u F_{1}^{u-p} + q_d F_{1}^{d-p}} \approx \left\{ \begin{array}{ll}
2 & f = u \\
1 & f = d
\end{array} \right. \quad (28a) $$

$$ \frac{F_{1}^{l^{12C}}}{q_u F_{1}^{u^{12C}} + q_d F_{1}^{d^{12C}}} \approx \left\{ \begin{array}{ll}
3 & f = u \\
3 & f = d
\end{array} \right. \quad (28b) $$

and using the expected sensitivities in Eq. (27), we can estimate that the constraints on $C/A^2$ from $p$ should be stronger by a factor of approximately

$$ 0.92 \cdot 0.3\% \quad \left\{ \begin{array}{ll}
\frac{2}{3} & f = u \\
\frac{1}{3} & f = d
\end{array} \right. \approx 1.7 \quad (29) $$

compared to $^{12}$C. This explains why couplings to down quarks are constrained to similar magnitude, while couplings to up quarks are better constrained by proton targets. These factors, however, are not exact, since we did not take radiative and form factor corrections into account.

### IV. OTHER OBSERVABLES

A number of different observables are suitable to constrain the relevant SMEFT operators or leptoquarks. Besides electron scattering, APV probes the same couplings. Additionally, we include bounds from the LHC on leptoquark production, as well as their contribution to Drell-Yan production of electron pairs. The operators involving lepton doublets can further be probed by coherent elastic neutrino-nucleus scattering (CEνNS), since they lead to analogous interactions of neutrinos with nuclei. However, currently CEνNS is not competitive with other constraints in this respect [85]. The current order of magnitude can be estimated by noting that the best constraints on neutrino Non-Standard Interactions (NSI) from CEνNS are at the order of $\epsilon_\nu \lesssim 0.5$ for vector interactions, while bounds on axial interactions are weaker [93, 94]. Using the mapping between NSI and SMEFT operators e.g. in Ref. [95], this can be translated to EFT scales of

$$ \Lambda \sqrt{C} \lesssim \left( \frac{G_F c_\nu}{\sqrt{2}} \right)^{-1/2} \approx 0.5 \text{ TeV} \quad (30) $$

| Leptoquark Coupling | $m_{LQ}$[TeV] | $P_2$ (p) | $P_2$ ($^{12}$C) | $A_{PV}^{LO}$ ($^{133}$Cs) | ATLAS dilepton |
|---------------------|--------------|----------|-----------------|--------------------------|-------------|
| $S_1$               | $s_{1L}$     | 6.6      | 4.2             | 2.2                      | 2.3         |
| $S_1$               | $s_{1R}$     | 6.6      | 4.2             | 5.4                      | 2.6         |
| $\tilde{S}_1$       | $\tilde{s}_1$| 4.5      | 4.2             | 5.7                      | 3.1         |
| $S_3$               | $s_3$        | 9.2      | 7.3             | 4.0                      | 5.0         |
| $V_2$               | $v_{2R}$     | 11.3     | 8.4             | 4.6                      | 8.7         |
| $V_2$               | $v_{2L}$     | 6.7      | 5.9             | 8.1                      | 6.5         |
| $V_3$               | $v_3$        | 9.0      | 5.9             | 7.6                      | 7.8         |
| $R_2$               | $r_{2R}$     | 7.9      | 5.9             | 3.3                      | 4.5         |
| $R_2$               | $r_{2L}$     | 6.4      | 4.2             | 5.4                      | 4.1         |
| $U_1$               | $u_{1L}$     | 6.4      | 5.9             | 3.4                      | 4.1         |
| $U_1$               | $u_{1R}$     | 6.4      | 5.9             | 8.1                      | 4.6         |
| $U_3$               | $u_3$        | 14.8     | 10.3            | 5.6                      | 10.8        |

which are well below the values in Table IV. Therefore, we focus on the constraints which are most competitive with $P_2$, namely those from APV and the LHC.

### A. Atomic parity violation

As in Ref. [71], we use the most precise measurement of APV which concerns the $6S_{1/2} - 2S_{1/2}$ nuclear transition in $^{133}$Cs. Following Ref. [70], we define the proton weak charge $Q_W (p)$ as the limit of the asymmetry at zero-momentum transfer, normalized such that the asymmetry formula (recall that $Q^2 = -q^2$)

$$ A_{PV}^{LO} = \frac{G_F Q^2}{\sqrt{2} 4\pi \alpha} Q_W (p) = \frac{G_F q^2}{\sqrt{2} 4\pi \alpha} Q_W (p) \quad (31) $$

holds, for which one can find from Eq. (21) that at leading-order the weak charge reads

$$ Q_W (p) = 1 - 4s_W^2 \quad (32) $$

Generalizing to nuclei, we simplify Eq. (20) to the form

$$ A_{PV}^{LO} = \frac{G_F q^2}{\sqrt{2} 4\pi \alpha F_{1}^{N_N} q_{u} + F_{1}^{N_N} q_{d}} \quad (33) $$

with

$$ Q_W (N) = 2 \left( F_{1}^{N_N} g_{V} + F_{1}^{dN} g_{V} \right) \approx Z(N)(1 - 4s_W^2) - N(N) \quad (34) $$

where $Z$ and $N$ denote the nuclear charge and number of neutrons, see also Ref. [96], such that

$$ Q_W (^{12}$C) \approx -24s_W^2, \quad Q_W (^{133}$Cs) \approx -23 - 220s_W^2 \approx -73.6 \quad (35a) $$

$$ Q_W (^{12}$C) \approx -24s_W^2, \quad Q_W (^{133}$Cs) \approx -23 - 220s_W^2 \approx -73.6 \quad (35b) $$
consistent with Eq. (22). For $^{133}\text{Cs}$, which has the currently best-measured asymmetry, we have used $Z_{\text{Cs}} = 55$ and $N_{\text{Cs}} = 78$. The SM prediction including radiative corrections and the measured values are given by [72]

$$Q_{W}^{\text{SM}}(^{133}\text{Cs}) = -73.23(1),$$  \hfill (36a)

$$Q_{W}^{\text{exp}}(^{133}\text{Cs}) = -73.71(35).$$  \hfill (36b)
FIG. 2. Expected 95% CL exclusion limits from P2 for vector leptoquarks assuming one coupling to dominate, compared to existing bounds from APV [72] and the LHC limits from pair production (PP) [73, 74], dilepton [75] and single resonant production (SRP) [76] channels. The constant ratios $m_{\text{LQ}}/g_{\text{LQ}}$ from P2, APV and ATLAS-Dilepton correspond to the entries of Table V.

These two numbers are consistent within 2\(\sigma\). We will use them nevertheless to illustrate how P2 could confirm or resolve the mild tension [72] between theory and experiment. From Eqs. (26a)-(26d) we can see how the measured value would be changed from the SM prediction through additional contributions to interactions at quark level at leading order. Note that therefore P2 data can be used to further investigate this deviation. We do so in Section V, finding that P2 should be able to rule out the necessary quark-level couplings at 95% CL. We can write,
for generic modifications $\Delta Q^\text{NP}_{W}$ of the weak charge,

$$A_{\text{PV}} = A_{\text{SM}} + \Delta A_{\text{PV}}^\text{NP} = \frac{G_F}{\sqrt{2}} \frac{q^2}{4\pi \alpha} Q^\text{SM}_{W}(N) + \Delta Q^\text{NP}_{W}(N),$$

(37)

with

$$\Delta Q^\text{NP}_{W}(N) = \Delta A_{\text{PV}}^\text{NP} \left( \frac{\sqrt{2}}{G_F} \frac{4\pi \alpha}{q^2} (F^u_{1-N} q_u + F^d_{1-N} q_d) \right).$$

In the limit $q^2 \to 0$ we conclude that, in the EFT picture,

$$\Delta Q^\text{NP}_{W}(133\text{Cs}) = \frac{\sqrt{2}}{G_F} \frac{1}{\Lambda^2} \left( F^u_{133\text{Cs}} (C_{LVu} - C_{RVu}) + F^d_{133\text{Cs}} (C_{LVd} - C_{RVd}) \right).$$

(38)

The momentum transfer in APV experiments is not exactly vanishing, but instead of the order of the inverse nuclear radius $Q \sim 1/r_0 \sim 30\text{MeV}$ according to Refs. [97, 98]. Other references set the momentum transfer at $Q \sim 2.4\text{MeV}$ which we will adapt here when considering leptoquark propagators [82]. However, even with such non-vanishing $Q$ the axial couplings will be poorly probed, since they contribute to $\Delta Q^\text{NP}_{W}$ only with a suppression factor of $Q/m_{W} \sim 10^{-5}$. To recast the bounds on $Q_{W}$ into 95% CL bounds on new physics, we will hence require that $Q^\text{NP}_{W}(133\text{Cs})$ does not deviate from $Q^\text{SM}_{W}$ by more than $\sqrt{3.84}$ standard deviations, neglecting the error of the SM prediction.

The results are included in Figures 1-2. It is interesting to note that we can identify two cases: Some leptoquarks increase $Q_{W}$ while others decrease it. Now since the SM expectation is already above the measured value, there is less room for new physics increasing $Q_{W}$ and more room for new physics decreasing $Q_{W}$. Therefore, the general pattern is that $P_{2}$ is expected to improve bounds on couplings decreasing $Q_{W}$ while bounds on couplings increasing $Q_{W}$ will likely remain better tested by APV.

B. Collider searches

Effective interactions between two quarks and two electrons as parametrized by the SMEFT operators of Eq. (A2) and as induced, for instance, by heavy leptoquarks according to the matching in Eqs. (6a)-(6g) can be tested at the LHC by searching for deviations from the SM in the Drell-Yan (DY) process $pp \to e^{+}e^{-}$. In the case of leptoquarks, this is mediated by a $t$-channel exchange of a leptoquark annihilating a quark-antiquark pair and producing an electron-positron pair. The latest results from the ATLAS experiment [75] are given in terms of limits on the contribution of new physics to the cross section in the signal region for the cases of constructive and destructive interference. To quantify constraints implied by these limits, we simulate the expected new-physics contributions to the cross section in the signal regions of invariant masses of the dilepton system $[2200, 6000]\text{GeV}$ (constructive interference) and $[2770, 6000]\text{GeV}$ (destructive interference) using MadGraph5 [100]. As further cuts we apply $p_T > 30\text{GeV}$ and $|\eta| < 2.47$ on the final state leptons, to approximate the ATLAS specifications. We use the same parton distribution function as specified in the ATLAS analysis, namely NNPDF23LO with the LHAPDF identifier 247000. To create UFO model files, we use FeynRules [101, 102] to extend the included SM model file by leptoquarks, or, to simulate SMEFT operators, by a heavy neutral vector boson with the appropriate couplings to match the considered Wilson coefficients.

The resulting lower bounds on the new-physics scale $\Lambda$ from SMEFT operators with unit Wilson coefficients consistent with the ATLAS search are given in Table IV. Similarly, the limits on leptoquark masses calculated for single unit Yukawa couplings are given in Table V and shown in Figures 1 and 2. We find that all couplings are currently constrained by the constructive interference bounds. As a consistency check of our results, we can compare the limit on the NP scale $\Lambda$ with ATLAS results. Since they assume equal couplings to up and down quarks, we can directly compare the operator $\mathcal{O}_{qe}$ which corresponds to the scenario $\eta_{LR} = 1$ referring to the effective Lagrangian in Equation 1 of Ref. [75]. This operator is also induced by the $r_{2R}$ leptoquark coupling. Therefore we can map both our EFT limit and our leptoquark limit to constraints on the scale $\Lambda_{\text{ATLAS}}$ used in Ref. [75] in the following way:

$$\frac{4\pi}{\Lambda_{\text{ATLAS}}} = \frac{|r_{2R}|^2}{2m_{R_2}^2} \Rightarrow \Lambda_{\text{ATLAS}} \geq \sqrt{8\pi m_{R_2}} = 22.6\text{TeV},$$

(39a)

$$\frac{4\pi}{\Lambda_{\text{ATLAS}}^2} = C_{qe} \Rightarrow \Lambda_{\text{ATLAS}} \geq \sqrt{4\pi C_{qe}} = 25.5\text{TeV}.$$  

(39b)

Comparing to the ATLAS result of $\Lambda_{\text{ATLAS}} \geq 24.7\text{TeV}$ we conclude that our method produces reasonable results. These results are also comparable to those obtained in Ref. [85].

The presence of leptoquarks can also be tested at proton colliders through pair production or single resonant production (SRP). While pair production through gluon fusion dominates for small Yukawa couplings $g_{LQ} \lessapprox 0.1-1$ since its cross section is determined by the strong gauge coupling, SRP can be relevant for larger couplings [76]. In Figures 1 and 2 we show bounds from SRP calculated in Ref. [76]. Turning to pair

---

2 The corresponding CMS limits [99] are weaker, so we only consider the ATLAS results.
production, in our cases for single leptoquark couplings to electrons and first-generation quarks, the resulting signal from the subsequent decays of the leptoquark pair is given by an $e^+ e^-$-pair and two jets. Assuming the lifetime of leptoquarks is short enough, this search yields a lower bound on the leptoquark mass. In Ref. [73] the search is done for scalar leptoquarks giving a lower limit on the mass of about 1.8 TeV at 95% CL for leptoquarks coupling to singlets. Following the prescription of Ref. [74], we rescale these limits by scaling the pair production cross sections of different leptoquarks depending on their coupling types and comparing them to the exclusion curve of Ref. [73]. The resulting bounds are included in Figures 1 and 2.

V. POTENTIAL TO RESOLVE DEGENERACIES USING MULTIPLE TARGETS

In Figure 3, we show for two SMEFT coefficients at a time how the different measurements constrain the combination of parameters and break degeneracies single measurements suffer from. While the seven parity-violating Wilson coefficients appearing in Eq. (3a) can be combined in 21 different ways, we only show some of the combinations, since many are basically equivalent. This is because the effective contribution to the asymmetry parameter for protons and nuclei is mainly controlled by the two effective up quark and down quark coupling coefficients

\begin{equation}
C_{PVu} = C_{LVu} - C_{RVu} = \frac{1}{2} \left( C_{lq(1)} - C_{lq(3)} - C_{qe} - C_{eu} + C_{lu} \right),
\end{equation}

\begin{equation}
C_{PVd} = C_{LVd} - C_{RVd} = \frac{1}{2} \left( C_{lq(1)} + C_{lq(3)} - C_{qe} - C_{ed} + C_{ld} \right),
\end{equation}

as one can see by adding up $\Delta A_{PV}^{LV/(N)}$ and $\Delta A_{PV}^{RV/(N)}$ in Eqs. (26a)-(26b) for up and down quarks, respectively. From this we can group coefficients into smaller sets which have a non-distinguishable effect. Namely,

- $C_{lq(1)}$ and $C_{qe}$ have the same effect (equal contribution to up and down couplings) with opposite sign.
- $C_{eu}$ and $C_{lu}$ have the same effect (contribution only to up couplings) with opposite sign.
- $C_{ed}$ and $C_{ld}$ have the same effect (contribution only to down couplings) with opposite sign.
- $C_{lq(3)}$ forms its own group (contribution to up and down couplings with same magnitude but opposite sign).

Therefore, we plot only one example of each of these groups in comparison in Figure 3. We find that the comparison of nuclei with protons is particularly good at resolving degeneracies between $C_{lq(3)}$ and other operators. However, the comparison between $p$ and $^{12}$C can also be expected to distinguish well between up quark and down quark interactions, as seen in the plot of $C_{eu}$ against $C_{ed}$. Moreover, if the SM expectation marked by an asterisk turns out to be correct (see the discussion after Eq. (36a)), we can see that the current best fit of APV, shown as dark green lines, can be expected to be ruled out by combining proton and $^{12}$C measurements of P2.

VI. CONCLUSION

In our study of the potential of the P2 experiment to test parity-violating new physics induced by SMEFT operators or leptoquarks, we found that P2 can be expected to be competitive with existing collider searches for such new physics and in many cases to have a better sensitivity to leptoquarks with masses above around 2 TeV. For all single operator scenarios and most single leptoquark scenarios, bounds from APV experiments with $^{133}$Cs can be exceeded by P2. We stress, however, that the complementarity of using different targets, for instance protons and $^{12}$C at P2, as well as $^{133}$Cs in APV will allow to better disentangle up and down quark interactions as illustrated in Figure 3. Moreover, a potential tension between theoretical and experimentally determined weak charges of $^{133}$Cs could be either confirmed or resolved at 95% CL by P2 data.

    u'_{La} &= (V^\dagger_{L})_{\alpha\beta} u_{L\beta}, & d'_{La} &= d_{La}, & e'_{La} &= e_{La}, \\
    u'_{Ra} &= u_{Ra}, & d'_{Ra} &= d_{Ra}, & e'_{Ra} &= e_{Ra},
\end{align}

(A1)
FIG. 3. Expected exclusion limits from P2 considering two SMEFT coefficients at a time, compared with existing measurement from APV [72]. The SM expectation is marked by an asterisk and the best fit to APV is shown as a dark green line. The EFT scale $\Lambda$ is set to 1 TeV.

The Wilson coefficients in Eq. (A2) are related to the Wilson coefficients $c^{e_r e_s \gamma \delta}$ defined for flavor eigenstates by the following identities for the parity-violating operators:

$$
\begin{align*}
\tilde{C}_{lq(1)} & = V_{u\gamma} V_{u\delta} C^{e_r e_s \gamma \delta}_{lq(1)} , \\
\bar{C}_{lq(1)} & = C^{e_r e_s \gamma \delta}_{lq(1)} , \\
C_{lu} & = C^{e_r e_s \gamma \delta}_{lu} , \\
C_{ld} & = C^{e_r e_s \gamma \delta}_{ld} , \\
C_{cu} & = C^{e_r e_s \gamma \delta}_{cu} , \\
C_{cd} & = C^{e_r e_s \gamma \delta}_{cd} .
\end{align*}
$$

(A3)

The notation of mass-basis coefficients is the same as it appears in Eq. (3a). Only two coefficients, $C_{lq(1)}$ and $C_{lq(3)}$ remain to be clarified. If we assume only first generation flavor couplings, we can set $\tilde{C}_{lq(1)} = $

with $V$ being the CKM matrix between primed flavor basis and unprimed mass basis, one finds

$$
\mathcal{L} = \frac{1}{\Lambda^2} \left\{ (\tilde{C}_{lq(1)} - \bar{C}_{lq(3)})(\bar{c}_{\gamma \mu} P_L e)(\bar{c}_{\gamma' \mu} P_L u) + C_{lu}(\bar{c}_{\gamma \mu} P_L e)(\bar{c}_{\gamma' \mu} P_R u) + (\tilde{C}_{lq(1)} + \bar{C}_{lq(3)})(\bar{c}_{\gamma \mu} P_L e)(\bar{d}_{\gamma' \mu} P_L d) + C_{ld}(\bar{c}_{\gamma \mu} P_L e)(\bar{d}_{\gamma' \mu} P_R d) + C_{q_e}(\bar{c}_{\gamma \mu} P_R e)(\bar{c}_{\gamma' \mu} P_L u) + C_{q_u}(\bar{c}_{\gamma \mu} P_R e)(\bar{d}_{\gamma' \mu} P_R d) + C_{q_d}(\bar{c}_{\gamma \mu} P_R e)(\bar{d}_{\gamma' \mu} P_R d) - C_{\bar{e}_{\mu\nu}}(\bar{c}_{\mu\nu} P_R e)(\bar{c}_{\mu\nu} P_R u) - C_{\bar{e}_{\mu\nu}}(\bar{c}_{\mu\nu} P_L e)(\bar{e}_{\mu\nu} P_L u) - C_{\bar{e}_{\mu\nu}}(\bar{c}_{\mu\nu} P_L e)(\bar{d}_{\mu\nu} P_R d) - C_{\bar{e}_{\mu\nu}}(\bar{c}_{\mu\nu} P_L e)(\bar{d}_{\mu\nu} P_R d) - C_{\bar{e}_{\mu\nu}}(\bar{c}_{\mu\nu} P_R e)(\bar{d}_{\mu\nu} P_R d) - C_{\bar{e}_{\mu\nu}}(\bar{c}_{\mu\nu} P_R e)(\bar{d}_{\mu\nu} P_R d) \right\} .
$$

(A2)
For the parity-conserving operators, we have

\[ |V_{ud}|^2 C_{lq(1)} - C_{lq(3)} = |V_{ud}|^2 (C_{lq(1)} - C_{lq(3)}) \],
\[ C_{lq(1)} + C_{lq(3)} = (C_{lq(1)} - C_{lq(3)}) \]. (A4)

For the parity-conserving operators, we have

\[ C_{lequ(1)} = V_{u\gamma}^* C_{lq(1)}, \]
\[ C_{lequ(3)} = V_{u\gamma}^* C_{lq(3)}, \]
\[ C_{ledq} = C_{ledq} \]. (A5)

Appendix B: Parametrization of the form factors

In this section we follow the notation of Ref. [70]. The electromagnetic Sachs form factors of the proton can be parametrized by a model multiplying a dipole and a polynomial,

\[ G_E^p = \left( 1 - \frac{q^2}{0.71 \text{GeV}^2} \right)^{-2} \left( 1 - \sum_{i=1}^{8} \kappa_i^E p q^{2i} \right) \], \hspace{1em} (B1a)
\[ G_M^p = \frac{\mu_p}{\mu_N} \left( 1 - \frac{q^2}{0.71 \text{GeV}^2} \right)^{-2} \left( 1 - \sum_{i=1}^{8} \kappa_i^M p q^{2i} \right) \], \hspace{1em} (B1b)

where \( \mu_p = 2.792847356 \mu_N \) denotes the proton’s magnetic moment and \( \mu_N = (e\hbar)/(2m_p) \) denotes the nuclear magneton. The fit coefficients \( \kappa_i \) are given in Tables 17 and 18 of Ref. [70]. For the neutron form factors we use

\[ G_E^n = \frac{\kappa_1^{E,n} r}{1 + \kappa_2^{E,n} r} \left( 1 - \frac{q^2}{0.71 \text{GeV}^2} \right)^{-2} \], \hspace{1em} (B2a)
\[ G_M^n = \sum_{i=0}^{9} \kappa_i^n M q^{2i} \], \hspace{1em} (B2b)

where \( r = -q^2/4m_n^2 \) and the coefficients being given in Tables 19 and 20 of Ref. [70]. For the strangeness form factors we use

\[ G_E^s = \frac{\kappa_1^{E,s} r}{1 + \kappa_2^{E,s} r} \left( 1 - \frac{q^2}{0.71 \text{GeV}^2} \right)^{-2} \], \hspace{1em} (B3a)
\[ G_M^s = \kappa_0^{M,s} - \kappa_1^{M,s} q^2 \], \hspace{1em} (B3b)

with the coefficients taken from Tables 21 and 22 of Ref. [70].
