Head injury from falls in children younger than 6 years of age

P Burrows,1 L Trefan,1 R Houston,2 J Hughes,1 G Pearson,3 R J Edwards,4 P Hyde,5 I Maconochie,6 R C Parslow,7 A M Kemp1

ABSTRACT
The risk of serious head injury (HI) from a fall in a young child is ill defined. The relationship between the object fallen from and prevalence of intracranial injury (ICI) or skull fracture is described.

Method Cross-sectional study of HIs from falls in children (<6 years) admitted to UK hospitals, analysed according to the object fallen from and associated Glasgow Coma Score (GCS) or alert, voice, pain, unresponsive (AVPU) and CT scan results.

Results Of 1775 cases ascertained (median age 18 months, 54.7% boys), 87% (1552) had a GCS=15/AVPU=alert. 19.3% (342) had a CT scan: 32% (110/342) were abnormal; equivalent to 5.9% of the overall population. 16.9% (58) had isolated skull fractures and 13.7% (47) had ICI (49% (23/47) had an associated skull fracture). The prevalence of ICI increased with neurological compromise; however, 12% of children with a GCS=15/AVPU=alert had ICI. When compared to falls from standing, falls from a person’s arms (233 children (mean age 1 year)) had a significant relative OR for a skull fracture/ICI of 6.94 (95% CI 3.54 to 13.6), falls from a building (eg, window or attic) (mean age 3 years) OR 6.84 (95% CI 2.65 to 17.6) and from an infant or child product (mean age 21 months) OR 2.75 (95% CI 1.36 to 5.65).

Conclusions Most HIs from a fall in these children admitted to hospital were minor. Infants, dropped from a carer’s arms, those who fell from infant products, a window, wall or from an attic had the greatest chance of ICI or skull fracture. These data inform prevention and the assessment of the likelihood of serious injury when the object fallen from is known.

INTRODUCTION
Head injury (HI) from a fall is a leading cause of hospital attendance for young children.1 The majority of these head injuries are minor; however, a small proportion result in intracranial injury (ICI) or skull fracture. They often report falls from the ‘same level’ or from ‘an estimated height’. Some studies with a biomechanical focus do highlight the objects and furniture involved in falls,10 11 however, small sample sizes prevent generalisation of these results.

What is already known on this topic?

▸ Falls are a common mechanism in young children admitted to hospital with head injury.
▸ Most are minor head injuries but can be associated with morbidity from post-concussion syndrome.
▸ The likelihood of cranial or intracranial damage from different fall mechanisms is ill defined.

What this study adds?

▸ Abnormal CT scans were identified in 5.9% of the children who had sustained head injury from a fall.
▸ The highest risk mechanism of fall for acquiring skull fracture or intracranial injury is an infant who is dropped from a carer’s arms.
▸ These data have the potential to inform prevention to reduce the number of infants and young children who sustain head injuries from falls.

METHODS
All cases described as falls were extracted from the CMACE dataset of children younger than 6 years of age, admitted to hospital or who died at the scene or en route to hospital as a direct result of an HI between September 2009 and February 2010. Children admitted because of superficial or facial
injuries were not included in the original dataset. Cases with insufficient data regarding the mechanism of injury, readmissions and those that were referred to social services for suspected physical abuse where there was uncertainty around the mechanism of injury were excluded. Cases that met clinical guidelines for a CT scan but where a CT scan had not been done were also excluded as we could not confirm the outcome.

Data were collected for this cross-sectional study monthly in each hospital using predefined proformas (see online supplementary file 1) by a designated local coordinator. Data from completed forms were entered onto a secure database and duplicate cases were excluded.

The child was classed as a hospital admission if they were admitted to a hospital inpatient setting for 4 h or more. The descriptions of falls were recorded using The European Union Injury Database Coding Manual. Incident place was coded according to home/private address, school/nursery, public highway/road/street/motorway other, unknown. Mechanism of injury: Falls were recoded as ‘Falls from standing or sitting’ and ‘Falls from a height’ and subcategorised according to falls from building, building component or related fitting, from person’s arms, downstairs, from furniture, infant or child product or other. Object fallen from were initially categorised in accordance with the coding manual. These categories were then condensed down into six larger categories (see online supplementary file 2) with relevant subdivisions.

The Glasgow Coma Score (GCS) recorded from the emergency department was the primary indicator of neurological status. When missing, the alert, voice, pain, unresponsive (AVPU) scores were used. These data were combined to create four categories—GCS=15/alert, ‘GCS=13–14’ GCS=9–12/ response to voice and ‘GCS ≤8/ response to pain or unresponsive’—as proposed by Mackay et al. (18). When Mackay et al. refer to children older than 5 years, this was the best equivalence study available.) CT scan results were categorised as normal (no abnormality reported on CT scan), isolated skull fracture or intracranial injury (ICI) (injury to the brain or extra-axial structures) with or without skull fracture. Structural anomalies congenital defects and soft tissue injuries were combined with CT normal group. Two coders independently reviewed CT scan details and agreed the categorisation of injury mechanism and objects fallen from.

HIs were classified as ‘minor’ if a CT scan was performed with a ‘normal’ result or no CT was performed but the GCS/AVPU score was GCS=15/alert.

Analysis of the dataset
A descriptive analysis used proportions with 95% CIs. The logistic regression analysis (IBM SPSS V20) was used to calculate the relative odds of sustaining a skull fracture or ICI from each mechanism to a fall from sitting or standing. A general model, including possible influencing covariates, namely mechanism of injury gender, age in years, was applied to the data and by a stepwise approach the statistically non-significant factors were removed from the model. To compare the accuracy of fit of the models, the software calculated fit statistics were used: (model) χ², –2 log-likelihood, overall percentage—the overall per cent of cases that are correctly predicted by the model (IBM SPSS V20). The best-fitting logistic model results are expressed as ORs, with 95% CIs.

RESULTS
The original dataset included 5700 children (ages of 0–15). Of these, 60% (3423) were <6 years, 76.9% (2634) of whom presented following a fall. In total, 153 cases referred to social services with suspected physical abuse, 11 cases that met criteria for a CT but CT scan was not done and 695 cases with insufficient data regarding the mechanism of injury were excluded. This latter group of cases had the same distribution of age, gender, GCS/AVPU and abnormal CT scan results as the remaining 1775 cases available for analysis (figure 1).

The median age of the children was 18 months (IQR 30 months). There was an inverse relationship between age and number of children who sustained HI from a fall (table 1). A slightly greater proportion of HIs occurred in boys (54.7%, n=971) than in girls.

Injury severity
A total of 1659 children had a GCS (1245) or an AVPU (414) recorded. Of the total population, 87% (1552/1775) had a GCS of 15 or were alert on AVPU. The length of stay was recorded for 1735 children. The median number of nights admitted was 1 (1005 children), 100 children were admitted for 2–4 nights, 8 for 5–7 days and 4 for more than a week, 616 were observed and sent home the same day. Two children died from their injuries.

CT scan was performed in 19.3% (342). A significantly greater proportion of children aged 3–5 years (26.6% (95% CI 22.9% to 30.6%)) than children younger than 3 years (16.5% (95% CI 14.5% to 18.6%)) had a CT scan (table 2). Overall 68% (233/342) had a normal CT, 16.9% (58) had isolated skull fractures, 13.7% (47) had ICI (49% (23) of whom had an associated skull fracture), and 4 were reported as abnormal but details were not given (tables 1 and 2). Children younger than a year had the greatest proportion of abnormal CT scans of 58% (58/100), 74.1% (43/58) of which were in children younger than 6 months of age. While the proportion of children with ICI increased with neurological compromise reflected by increased GCS/AVPU, ICI was identified in 12% (31/260) of children with a GCS=15/AVPU=alert who had a CT scan (table 2).

Also, 62 of the 81 skull fractures were simple linear fractures (41 parietal/temporal, 6 frontal, 11 occipital, 2 basal, 2 location not recorded), 13 were complex fractures (5 bilateral and 7 depressed fractures, 1 multiple). In six cases, neither the site nor type was specified. There was no difference between the distribution of fracture type or site between the children who had coexisting ICI. Twenty-three children had fractures with ICI, in 22 there were underlying extra-axial haemorrhage, contusions

Original article

Arch Dis Child: first published as 10.1136/archdischild-2014-307119 on 21 August 2015. Downloaded from http://adc.bmj.com/ on October 13, 2023 by guest. Protected by copyright.
were described in 2 cases and cerebral oedema in 1. In the 24 children with ICI but no skull fractures, the ICI included contusions (5), intracranial haemorrhage (3), extra-axial haemorrhage (15) and cerebral oedema (1).

Characteristics of the causal event
The majority (74.1% (1316/1775)) of HIs occurred in the home. Falling from a height accounted for 74.5% (1322/1775). Children who fell from a height were more likely to sustain skull fractures or ICI than those who fell from standing (7.4% (98/1322) vs 2.7% (12/453)). The calculated relative OR of this relationship was 2.9 (95% CI 1.6 to 5.4). There was a relationship between the age of the children and the mechanism of injury; young babies fell or were dropped from a carer’s arms, toddlers who fell down the stairs or from furniture had a median of 18 months, 1 year olds fell from an infant product while the older children fell from standing or from walls, windows, shopping trolleys, and so on (table 3).

The three mechanisms with the greatest proportions of abnormal CT were falls from (1) a person’s arms, (2) building or building component (11 from a wall, 19 from window, 6 from attic, 6 balcony/banister/gallery/ stage, 6 from bathroom furnishings or gate, 3 from patio) and (3) an infant or child product. Stepwise elimination of co-covariates in the logistic regression model resulted in only the mechanism of injury remaining in the model. The relative ORs for sustaining a skull fracture or ICI were significantly greater than a fall from standing or sitting, namely 6.94 (95% CI 3.54 to 13.6), 6.84 (95% CI 2.65 to 17.6) and 2.75 (95% CI 1.36 to 5.65), respectively (table 3).

A child who fell from a carer’s arms down the stairs had a greater chance (23.3% (95% CI 13.2% to 37.8%) (10/43)) of sustaining a skull fracture or ICI compared with those who were dropped on to the floor (14.2% (95% CI 10% to 19.9%) (27/190)).

Figure 2 outlines the reported objects that 1775 children had fallen from. With the exception of falls from a carer’s arms, from a building or an infant child product, there were no significant statistical differences in the proportion of abnormal CT findings among any of the other categories.

DISCUSSION
The greatest proportion of the children who were admitted to hospital following an HI from a fall were younger than 1 year. One-fifth of the children had a CT scan to confirm or exclude ICI. One-third of which had an abnormality reported, equivalent to 5.9% of the overall population studied. The most

| Table 1 | Number and proportion of children who had a CT scan and CT findings by age |
|---------|------------------------------------------------------------------------|
| Children age (years) | No. children who had CT scan | Minor HI* | Isolated skull fracture | ICI with/without skull fracture | CT scan stated as abnormal but no results given | Total |
| <1 | 100 | 545 | 36 | 20 | 2 | 603 |
| 1 | 69 | 408 | 14 | 51 | 1 | 429 |

| Total | 233 | 58 | 47 | 4 | 342 |

AVPU, alert, voice, pain, unresponsive; GCS, Glasgow Coma Score; ICI, intracranial injury.
The common abnormal finding was a skull fracture, most commonly a simple linear parietal fracture, a proportion (1 in 4) of these had an underlying extra-axial haemorrhage. Few children sustained an ICI without skull fracture. These findings are similar to those of Dietrich et al.\(^1\) and to a recent publication by Thomas et al.\(^2\) for children younger than 2 years old. The latter study identified ‘isolated skull fractures’ in 19.5% of children who had neuroimaging for head injuries and focal intracranial haemorrhage in 15.4%. Although the study included all mechanisms of injury, 82% of the series were from falls.

The highest rate of abnormal CT scans was evident in infants who fell from a parent’s arms, a finding consistent with other studies.\(^5\) The likelihood of an abnormal CT scan was greater for children dropped on the stairs compared with those dropped on to the floor. By contrast, falls down stairs, which were one of the most common reasons for hospital admission, resulted in a low prevalence of skull fracture or ICI.

Table 3 CT outcome by mechanism with relative 95% CI of sustaining a skull fracture or intracranial injury (ICI) from each mechanism compared with a fall from sitting or standing

| Mechanism                                      | Median age years (IQR) | CT: normal         | CT: skull fracture | CT: ICI with/without skull fracture | CT: abnormal scan/died | Total | Odds ratios of skull fracture or ICI to fall from standing/sitting | p Value |

| Persons arms                                   | 0.3 (1.1)              | 196 (84.1%)        | 21 (9%)            | 15 (6.4%)                           | 1 (0.4%)               | 233   | 6.94 (3.54 to 13.6)                                                | <0.001  |
| Building, building component or related fitting| 3.2 (2.6)              | 43 (84.3%)         | 2 (3.9%)           | 5 (9.8%)                            | 1 (2%)                 | 51    | 6.84 (2.65 to 17.6)                                                | <0.001  |
| Other                                          | 3.3 (2.5)              | 52 (92.9%)         | 2 (3.6%)           | 1 (1.8%)                            | 1 (1.8%)               | 56    | 2.83 (0.89 to 9.09)                                                | 0.081   |
| Infant or child product                        | 0.9 (2.8)              | 334 (93%)          | 17 (4.7%)          | 8 (2.2%)                            | 0                      | 359   | 2.75 (1.36 to 5.56)                                                | 0.005   |
| Furniture                                      | 1.5 (1.8)              | 388 (95.8%)        | 8 (2%)             | 7 (1.7%)                            | 2 (0.5%)               | 405   | 1.61 (0.76 to 3.41)                                                | 0.214   |
| Stairs                                         | 1.5 (1.3)              | 211 (96.8%)        | 2 (0.9%)           | 5 (2.3%)                            | 0                      | 218   | 1.22 (0.47 to 3.14)                                                | 0.682   |
| Standing/sitting                               | 2.4 (2.8)              | 441 (97.4%)        | 6 (1.3%)           | 6 (1.3%)                            | 0                      | 453   |                                                                     |         |
| Total                                          | 1665 (93.8%)           | 58 (3.3%)          | 47 (2.6%)          | 5 (0.3%)                            |                        | 1775  |                                                                     |         |

Infant product included cot, Moses basket, high chair or pram.
Building or building component included wall, window, attic, balcony/banister/gallery/stage, bathroom furnishings, gate, patio.

The strength of this study is the large national dataset and representative sample. The data were limited to hospital admissions and are likely to be biased by injury severity, clinical decisions to admit cases and variation in admission policy and facilities across the UK. While there were clear national HI guidelines in place at the time of the study,\(^15\) adherence to guidelines varied and results could only be based on the CT findings according to the level of investigations undertaken. The study does not include the many children who were assessed in the emergency department and discharged home. Children referred to social services were excluded due to uncertainty about mechanism, some of which may have been genuine falls once child protection investigations were completed, but this information was not available to us. Equally it is possible that the dataset includes unrecognised cases of physical abuse. Data were collected over a 6-month winter period and are likely to have missed the summer peak incidence or seasonal variation in injury type.\(^4\)
Much of the information processed and coded was written in free text, creating an element of subjectivity when categorising data. The data had been collected from >200 hospitals, and the quality of data entry varied. However, after exclusion of cases with poor data quality, we are confident that the dataset represents a cross section of falls in preschool children who were admitted to hospital. Although the Injury Database manual was used as a coding standard for consistency, the manual is not designed specifically for falls and was thus adapted for the population studied to include some of the emergent categories.

The increased likelihood of a skull fracture or ICI from a fall from height compared with falling from standing height was unsurprising. The height of a fall in this study was estimated in terms of the nature of the item fallen from, and this is frequently all that the clinician has to inform a clinical assessment when assessing the likelihood of cranial or intracranial structural damage.

Estimating a fall height threshold for serious HI is a debated topic. In 1991, Williams described how infants who fell from <10 ft (3 m) were unlikely to sustain serious injuries (intracranial haemorrhages, cerebral oedema, depressed skull fractures and compound or comminuted fractures), while in 2008 Chadwick et al. published a systematic review estimating a mortality rate of <0.48 deaths per one million children in the USA for children involved in short falls of <3 ft (<1 m). In 2012, Ibrahim et al. acknowledged that falls from a greater height could result in incrementally more serious injury but suggested that there were multiple factors to consider such as the angle of the fall, impact and landing position of the child (all beyond the scope of this study). Although we were unable to make height estimates, our results show a lower proportion of skull fractures or ICI after a fall from standing or from low-height furniture than from falls from windows and other building components, or from a carer’s arms.

Most infant falls are short vertical falls; however, being dropped may result in a child being released at an angle causing a non-linear fall and rapid angular deceleration on impact with the ground. The biomechanics involved when a child that is dropped down the stairs is complex. We hypothesise that the height of the initial fall before contact with the stairs increases the momentum with which the child continues to tumble down the stairs, increasing the complexity of the fall and the likelihood of sustaining a skull fracture or ICI. The proportion of children who sustain a skull fracture or ICI after falling down the stairs without being dropped was considerably lower (3.4% vs 26.2%). This mechanism has been described as a series of short falls between each individual step. There is a culture of anxiety concerning children falling down stairs. A retrospective study estimates that a child under the age of 5 is seen every six minutes for a stair-related fall in US emergency departments. This study extends our understanding of HI from falls and the risk of skull fracture or ICI given the age of the child and item fallen from. It identifies the dangers of dropping children while confirming that low height falls, including simple stair falls, rarely cause impaired consciousness, skull fractures or ICI. The findings have the potential to inform HI clinical decision rules about falls that warrant a CT scan. Currently, this varies from a fall of 3 ft or more or five stairs (Canadian Assessment of Tomography for Childhood Head Injury), falls that exceed 0.9 m for children younger than 2 years or >1.5 m (5 ft) for older children (Pediatric Emergency Care Applied Research Network) to falls that exceed 3 m (Children’s Head Injury Algorithm for the Prediction of Important Clinical Events). Child protection specialists can apply the findings to inform decisions about the plausibility of injury explanations when assessing infants and young children with suspected physical abuse. Prevention initiatives should stress the importance of carrying children safely, particularly while going up and downstairs.

RJE, PH, IM and RCP were all members of the project Independent Advisory Board and gave advice and editorial supervision at regular intervals during the study analysis. AMK supervised the student project, coordinated the study writing, checked and edited the manuscript, agreed the concept and methodology of this particular analysis.

**Data sharing statement** The data that informs this study is an anonymised national dataset and is available upon request for individuals who have a worthy cause to analyse as long as the rationale fits with the ethical approval and Section 251 requirements. We would consult with such bodies as necessary.

**Open Access** This is an Open Access article distributed in accordance with the Creative Commons Attribution Non Commercial (CC BY-NC 4.0) license, which permits others to distribute, remix, adapt, build upon this work non-commercially, and license their derivative works on different terms, provided the original work is properly cited and the use is non-commercial.
