CM CONGRUENCE AND TRIVIAL ZEROS OF THE KATZ
\( p \)-ADIC \( L \)-FUNCTIONS FOR CM FIELDS

ADEL BETINA AND MING-LUN HSIEH

Abstract. The aim of this paper is to investigate the trivial zeros of the Katz \( p \)-adic \( L \)-functions by the CM congruence. We prove the existence of trivial zeros of the Katz \( p \)-adic \( L \)-functions for general CM fields and establish a first derivative formula of the cyclotomic \( p \)-adic \( L \)-functions at trivial zeros under some Leopoldt hypothesis. The crucial ingredients in our proof are a special case of \( p \)-adic Kronecker limit formula for CM fields and a leading term formula of anticyclotomic \( p \)-adic \( L \)-functions at trivial zeros via the explicit congruences between CM and non-CM Hida families of Hilbert cusp forms.

1. Introduction

1.1. Conjectures on trivial zeros of the Katz \( p \)-adic \( L \)-functions. Let \( F \) be a totally real number field of degree \( d \) and absolute discriminant \( \Delta_F \). Let \( K \) be a totally imaginary quadratic extension of \( F \). Let \( p \) be a prime number. Fix once and for all embeddings \( \iota_\infty : \Q \to \C \) and \( \iota_p : \Q \to \Q_p \) singling out a decomposition subgroup of \( G_\Q := \text{Gal}(\Q/\Q) \) at \( p \). Let \( c \in \text{Gal}(K/F) \) be the non-trivial automorphism. We suppose throughout this paper the following ordinary hypothesis on the CM field \( K \):

\text{(ord)} Every prime factor of \( p \) in \( F \) splits in \( K \).

Let \( \Sigma \subset \text{Hom}(K, \C) \) be a \( p \)-ordinary CM-type of \( K \), i.e.

\begin{itemize}
  \item \( \Sigma \cup \Sigma c = \text{Hom}(K, \C) \) and \( \Sigma \cap \Sigma c = \emptyset \);
  \item the set \( \Sigma_p \) of \( p \)-adic places induced by elements in \( \Sigma \) composed with \( \iota_p \iota_\infty^{-1} \) is disjoint from \( \Sigma_p c \).
\end{itemize}

The hypothesis \text{(ord)} assures the existence of \( p \)-ordinary CM-types and we fix one such \( \Sigma \). Denote by \( \bar{K}_\infty \) for the compositum of all the \( \Z_p \)-extensions of \( K \) and by \( K_{\Sigma_p} \) for the maximal sub-extension of \( \bar{K}_\infty \) unramified outside \( \Sigma_p \). In fact, \( \text{Gal}(K_{\Sigma_p}/K) \simeq \Z_p^{1+\delta_{F,p}} \) and \( \text{Gal}(\bar{K}_\infty/K) \simeq \Z_p^{d+1+\delta_{F,p}} \), where \( \delta_{F,p} \) is the Leopoldt defect for \( F \) and \( p \). Let \( \mathcal{W} \) be a finite extension of the completion \( \bar{Z}_p \) of the maximal unramified extension of \( \Z_p \) in \( \Q_p \). To each choice of \( p \)-ordinary CM type \( \Sigma \) and a ray class character \( \chi \) of \( K \) valued in \( \mathcal{W} \), one can attach the Katz \( p \)-adic \( L \)-function \( L_{\Sigma}(\chi) \in \mathcal{W}[[\text{Gal}(\bar{K}_\infty/K)]] \) constructed by Katz [Kat78] and Hida–Tilouine.

1
This $p$-adic $L$-function $\mathcal{L}_\Sigma(\chi)$ is uniquely characterized by the following interpolation property: there exists a complex period

$$
\Omega = (\Omega_\sigma)_{\sigma \in \Sigma} \in (\mathbb{C}^\times)^\Sigma
$$

and a $p$-adic period

$$
\Omega_p = (\Omega_{p,\sigma})_{\sigma \in \Sigma} \in (\mathcal{W}^\times)^\Sigma
$$

such that for every crystalline character $\phi : \text{Gal}(\overline{K}_\infty/K) \to \overline{\mathbb{Q}}_p^\times$ of weight $k\Sigma + j(1-c)$ for some integer $k$ and $j = \sum_{\sigma \in \Sigma} j_\sigma \sigma \in \mathbb{Z}[\Sigma]$ with either $k > 0$ and $j_\sigma \geq 0$ or $k \leq 1$ and $j_\sigma + k \geq 1$, we have

$$
\frac{\nu_\phi(\mathcal{L}_\Sigma(\chi))}{\Omega_p^{k\Sigma+2j}} = \frac{[\sigma_K^\times : \sigma_p^\times]}{2^d} \frac{1}{(\sqrt{-1})^{k\Sigma+j}} \frac{\Gamma_C(k\Sigma+j)\mathcal{L}_{\text{fin}}(0,\chi_{\phi_{\Sigma}})}{\Omega_p^{k\Sigma+2j}} \prod_{\eta \in \Sigma_p} (1 - \chi_{\phi_{\Sigma}}(\overline{\eta})) (1 - \chi_{\phi_{\Sigma}}(\overline{\eta}^{-1})\mathcal{N}\overline{\eta}^{-1}),
$$

(1.1)

where

- $\nu_\phi : \mathcal{W}[\text{Gal}(\overline{K}_\infty/K)] \to \overline{\mathbb{Q}}_p$ is the unique $\mathcal{W}$-algebras homomorphism such that $\nu_\phi(\text{Gal}(\overline{K}_\infty/K)) = \phi$,
- $\phi_{\Sigma}$ is the grossencharacter of type $A_0$ associated with $\phi$ such that $\phi_{\Sigma}(\mathcal{O})$ is the value of $\phi$ at the geometric Frobenius $\text{Fr}_{\mathcal{O}}$ at primes $\mathcal{O} \mid p$,
- $\mathcal{L}_{\text{fin}}(s,\chi_{\phi}) = \sum_n \chi_{\phi_{\Sigma}}(n)\mathcal{N}a_n^{-s}$ is the classical $L$-series of $\chi_{\phi_{\Sigma}}$ where $a_n$ runs over all integral ideals of $K$ relatively prime to the conductor of $\chi_{\phi_{\Sigma}}$.
- $\overline{\eta} = c(\overline{\eta})$.

In the expression of (1.1), we have used the convention for $\xi = \sum_{\sigma \in \Sigma} \xi_\sigma \sigma \in \mathbb{Z}[\Sigma]$, and for $x = (x_\sigma) \in \mathbb{C}^\Sigma$:

$$
x^\sigma = \prod_{\sigma \in \Sigma} x_\sigma^\sigma; \quad \Gamma_C(\xi) = \prod_{\sigma \in \Sigma} 2(2\pi)^{-\xi_\sigma} \Gamma(\xi_\sigma).
$$

Any element $a \in \mathbb{C}^\Sigma$ is considered to be an element of $\mathbb{C}^\Sigma$ via the diagonal embedding $a \mapsto (a)_{\sigma \in \Sigma}$.

For each positive integer $m$, denote by $Q(\zeta_m)$ the $m$-th cyclotomic field. Let $Q(\zeta_{p^n}) = \bigcup_{n=1}^{\infty} Q(\zeta_{p^n})$ and denote by $e_{\text{cyc}} : \text{Gal}(Q(\zeta_{p^n})/Q) \xrightarrow{\sim} \mathbb{Z}_p^\times$ be the usual $p$-adic cyclotomic character. Let $Q_{\infty} \subset Q(\zeta_{p^n})$ be the cyclotomic $\mathbb{Z}_p$-extension of $Q$. We view $Q(\mathcal{K}_\infty/Q)$ as a subgroup of $\text{Gal}(Q(\zeta_{p^n})/Q)$ via the isomorphism $\text{Gal}(Q(\zeta_{p^n})/Q) \simeq \text{Gal}(Q_{\infty}/Q) \times \text{Gal}(Q(\zeta_{p^n})/Q)$, $\sigma \mapsto (\sigma|_{Q_{\infty}}, \sigma|_{Q(\zeta_{p^n})})$. Let $K_{\Sigma} = Q_{\infty}K$ be the cyclotomic $\mathbb{Z}_p$-extension of $K$ and let $\langle e_{\text{cyc}} \rangle : \text{Gal}(K_{\infty}/K) \to \mathbb{Z}_p^\times$ be the character defined by the composition

$$
\text{Gal}(\overline{K}_\infty/K) \to \text{Gal}(K_{\Sigma}^+/K) \to \text{Gal}(Q_{\infty}/Q) \xrightarrow{\langle e_{\text{cyc}} \rangle} \mathbb{Z}_p^\times.
$$

We consider the cyclotomic Katz $p$-adic $L$-function defined by

$$
L_{\Sigma}(s,\chi) := (e_{\text{cyc}})^s(\mathcal{L}_\Sigma(\chi)), \quad s \in \mathbb{Z}_p.
$$

Let us put

$$
\Sigma_{p,\text{irr}} = \{ \mathcal{P} \in \mathbb{Z}_p \mid \chi(\overline{\mathcal{P}}) = 1 \};
$$

$$
r_{\Sigma}(\chi) = \# \Sigma_{p,\text{irr}} - \dim_{\mathfrak{m}} H^0(K, \chi).
$$
In view of the interpolation formula (1.1), we expect that \( L_\Sigma(s, \chi) \) has a trivial zero whenever \( r_\Sigma(\chi) > 0 \). By analogy to a conjecture of Gross regarding the order of vanishing of Deligne-Ribet p-adic L-functions, we have the following conjecture regarding the order of the vanishing of \( L_\Sigma(s, \chi) \) at \( s = 0 \).

**Conjecture 1.** We always have

\[ \text{ord}_{s=0} L_\Sigma(s, \chi) = r_\Sigma(\chi). \]

Note that when \( K \) is an imaginary quadratic field, the implication \( r_\Sigma(\chi) > 0 \Rightarrow L_\Sigma(0, \chi) = 0 \) follows from the p-adic Kronecker limit formula, but in general it is not clear if \( L_\Sigma(s, \chi) \) possesses a zero at \( s = 0 \) when \( r_\Sigma(\chi) > 0 \) since \( s = 0 \) is not a critical point for \( \chi \) and is outside the range of the interpolation of \( L_\Sigma(s, \chi) \).

We briefly recall the conjectural formula of the leading term of \( L_\Sigma(s, \chi) \) at the trivial zero in [BS19]. First we prepare some crucial ingredients in the statement of this formula. Following the notation in [Gro81], if \( X \) is an abelian group and \( R \) is a ring, we denote the \( R \)-module \( R \otimes \mathbb{Z} X \) simply by \( RX \). Let \( H := \mathbb{Q}_p(\chi) \) be the finite cyclic extension of \( K \) cut out by \( \chi \) and \( G := \text{Gal}(H/K) \). Let \( \mathfrak{o}_H^\times \) the group of units of \( H \). Put

\[ \mathfrak{o}_H^\times \sigma[\chi] := e_\chi \big( \mathbb{Q}_p, \mathfrak{o}_H^\times \big), \]

where \( e_\chi \) is the usual idempotent

\[ e_\chi = \frac{1}{[H : K]} \sum_{\tau \in G} \chi(\tau^{-1}) \otimes \tau. \]

Let \( \log_p : \mathbb{Q}_p^\times \to \mathbb{Q}_p \) denote the Iwasawa’s p-adic logarithm with \( \log_p(p) = 0 \). Let \( \Sigma_H \) be the set of embeddings \( \sigma_H : H \to \mathbb{C} \) extending those in \( \Sigma \) and let \( G \) act on \( \Sigma_H \) by \( \tau \cdot \sigma = \sigma \circ \tau^{-1} \) for \( \tau \in G \) and \( \sigma \in \Sigma_H \). Let \( Y_{H, \Sigma} \) be the free abelian group on \( \Sigma_H \), regarded as a \( \mathbb{Z}[G] \)-module with the the action of \( G \)-action on \( \Sigma_H \). Define the \( p \)-adic regulator map

\[ \log_{\Sigma, p} : H^\times \to \mathbb{Q}_p Y_{H, \Sigma}, \quad \log_{\Sigma, p}(x) = \sum_{\sigma \in \Sigma_H} \log_p(\iota_p \sigma(x)) \sigma. \]

We extend the map \( \log_{\Sigma, p} \) by linearity to the map \( \log_{\Sigma, p} : \mathbb{Q}_p H^\times \to \mathbb{Q}_p Y_{H, \Sigma} \) of \( \mathbb{Q}_p[G] \)-modules and obtain a map between the \( \chi \)-isotypic parts on the both sides

(1.2) \[ \log_{\Sigma, p} : \mathfrak{o}_H^\times[\chi] \to Y_{H, \Sigma}[\chi] := e_\chi(\mathbb{Q}_p Y_{H, \Sigma}). \]

**Conjecture 2** (The \( \Sigma \)-Leopoldt conjecture for \( \chi \)). The map \( \log_{\Sigma, p} \) in (1.2) is injective.

We remark that Conjecture 2 is a consequence of the well-known \( p \)-adic Schanuel conjecture as explained in [HT94] Lemma 1.2.1]; the four exponential conjecture implies Conjecture 2 when \( F \) is a real quadratic field. Fixing an isomorphism \( \iota : \mathbb{C} \cong \mathbb{Q}_p \) such that \( \iota \circ \iota_\infty = \iota_p : \mathbb{Q} \hookrightarrow \mathbb{Q}_p \), the Dirichlet regulator map is defined by

\[ \log_{\Sigma, \infty} : H^\times \to \mathbb{Q}_p Y_{H, \Sigma}, \quad \log_{\Sigma, \infty}(x) = \sum_{\sigma \in \Sigma_H} \iota(\log |\sigma(x)|) \sigma. \]

Suppose that \( \chi \) is not the trivial character 1. By Dirichlet’s units Theorem, the induced map \( \log_{\Sigma, \infty} : \mathfrak{o}_H^\times[\chi] \xrightarrow{\sim} Y_{H, \Sigma}[\chi] \) is an isomorphism of \( d \)-dimensional \( \mathbb{Q}_p \)-vector spaces. It follows that if Conjecture 2 holds, then the \( p \)-adic regulator map
introduce the cyclotomic \( R \). Let \( o \). It is clear that the restriction of \( \sigma \) to \( \Sigma \)-Leopoldt conjecture for \( \chi \) is equivalent to the non-vanishing of \( \Delta \). Following Buyukboduk and Sakamoto [BS19, Definition 5.2], we next introduce the cyclotomic \( \ell \)-invariant for \( \chi \neq 1 \) under the \( \Sigma \)-Leopoldt conjecture. Let \( \sigma_{H,\Sigma}^\times \) be the \( \Sigma \)-units in \( H \) and put

\[
\sigma_{H,\Sigma}^\times [\chi] := e_\chi \left( \mathbb{Q}_p, \sigma_{H,\Sigma}^\times \right).
\]

We consider the space

\[
U_\chi := \ker \left\{ \sigma_{H,\Sigma}^\times [\chi] \rightarrow \mathbb{Q}_p \right\}.
\]

If \( \mathfrak{p} \) is a prime ideal of the ring \( o \) of \( \mathbb{K} \), let \( \text{ord}_\mathfrak{p} : K^\times \mathfrak{p} \rightarrow \mathbb{Z} \) be the normalized valuation map and \( \log_\mathfrak{p} := \log \circ N_{\mathfrak{K}/\mathbb{Q}_p} : K^\times \mathfrak{p} \rightarrow \mathbb{Z}_p \) be the cyclotomic \( p \)-adic logarithm, where \( N_{\mathfrak{K}/\mathbb{Q}_p} \) is the norm map from \( \mathfrak{K} \) to \( \mathbb{Q}_p \). For each \( \mathfrak{p} \in \Sigma^\mathfrak{p}_H \), we choose a prime \( \overline{\mathfrak{p}}_H \) of \( H \) above \( \mathfrak{p} \). Then via the inclusion \( \sigma_{H,\Sigma}^\times \subset H^\times \subset H^\times_{\overline{\mathfrak{p}}_H} = K^\times \), we can evaluate \( \text{ord}_{\overline{\mathfrak{p}}} \) and \( \log_{\overline{\mathfrak{p}}} \) on \( \sigma_{H,\Sigma}^\times \) and extend by linearity to maps

\[
O_p : U_\chi \rightarrow \mathbb{Q}_p^\times \rightarrow \mathbb{Q}_p^\times ;
\]

\[
L_p : U_\chi \rightarrow \mathbb{Q}_p^{\times \log} \rightarrow \mathbb{Q}_p^{\times \log}.
\]

If \( \chi \neq 1 \) and the \( \Sigma \)-Leopoldt conjecture for \( \chi \) holds, the first map \( O_p \) is an isomorphism; we can define the cyclotomic \( \ell \)-invariant of \( \chi \) by

\[
\ell_\chi := (-1)^{\tau_\chi}(\chi) \text{ det } \left( O_p^{-1} \circ L_p \right).
\]

Note that the definition of \( \ell_\chi \) does not depend on the choice of the prime \( \overline{\mathfrak{p}}_H \) above \( \mathfrak{p} \).

For any \( \mathbb{Z}_p \)-extension \( K^\Gamma \) of \( \mathbb{K} \) with the Galois group \( \Gamma \), we can also consider the trivial zeros of the Katz \( p \)-adic \( L \)-function \( L_\Sigma(\chi) \mid \Gamma \in \mathcal{W}[\Gamma] \) obtained by the restriction of \( L_\Sigma(\chi) \) to \( \Gamma \). It is shown in [BS19, Theorem 1.1] that the leading term formula of \( L_\Sigma(\chi) \mid \Gamma \) at the trivial zero can be obtained as a consequence of several outstanding open conjectures in algebraic number theory, eg. Rubin-Stark conjecture and the Reciprocity Conjecture. The following is the special case of this conjectural leading term formula when \( K^\Gamma = K^\times_\infty \) is the cyclotomic \( \mathbb{Z}_p \)-extension.

**Conjecture 3.** Assume the validity of the \( \Sigma \)-Leopoldt conjecture for \( \chi \) and \( \chi \neq 1 \). Then we have \( \sum_{s=0} L_\Sigma(s, \chi) \geq r_\Sigma(\chi) \) and

\[
\lim_{s \to 0} \frac{L_\Sigma(s, \chi)}{s^{r_\Sigma(\chi)}} = (-1)^{\tau_\chi}(\chi) \ell_\chi \prod_{\mathfrak{p} \in \Sigma^\mathfrak{p} \setminus \Sigma^\mathfrak{p}_H} \left( 1 - \chi(\mathfrak{p}) \right)
\]

\[
\times \prod_{\mathfrak{p} \in \Sigma_p} \left( 1 - \chi(\mathfrak{p}^{-1})N\mathfrak{p}^{-1} \right) \cdot \Delta(\Sigma(\chi)) \cdot L_\text{fin}^*(0, \chi),
\]

where \( L_\text{fin}^*(0, \chi) := t \left( \lim_{s \to 0} s^{-d}L_\text{fin}(s, \chi) \right) \in \mathbb{Q}_p^\times \) is the leading term of the \( \ell \)-series \( L_\text{fin}(s, \chi) \).
When $K$ is an imaginary quadratic field (so $r_\Sigma(\chi) \leq 1$), Conjecture $\dagger$ is equivalent to the non-vanishing of the $L$-invariant, which is known to be a consequence of the four exponentials conjecture ([BD21, Prop. 1.11]), Conjecture $\ddagger$ holds thanks to the Baker-Brumer Theorem and Conjecture $\S$ is proved in [BS19, Theorem 1.6] via the Euler system of elliptic units. These conjectures are still wide open for general CM fields.

1.2. Statement of the main results. The main goal of this article is to prove the existence of the trivial zeros and provide some evidence towards Conjecture $\dagger$ for general CM fields in the rank zero and one case under the Leopoldt hypotheses. Our method does not rely on the existence of conjectural Rubin-Stark units and conjectural reciprocity law. In the course of the proofs, we also obtain a leading term formula of the anticyclotomic Katz $p$-adic $L$-functions.

Let $h_{K/F}$ be the relative class number of $K/F$ and $D_{K/F}$ be the relative different of $K/F$. For simplicity, it is assumed throughout this introduction that $(\chi,K,p)$ satisfies the following technical conditions.

(H1) The prime $p$ does not divide $6\Delta_F h_{K/F}$;
(H2) $\chi$ is of prime-to-$p$ order and is unramified at primes dividing $pD_{K/F}$.

Note that these assumptions are satisfied by all but finitely primes $p$ once $(\chi,K)$ is fixed. Our first result gives a sufficient and necessary condition for the existence of the trivial zero, i.e. Conjecture $\dagger$ in the rank zero case under the following Leopoldt hypothesis.

**Hypothesis (L).** The Leopoldt conjecture for $F$ and the $\Sigma$-Leopoldt conjecture for $\chi$ both hold.

**Theorem A.** Suppose that Hypothesis (L) is valid. Then we have

$$\text{ord}_{s=0} L_\Sigma(s,\chi) = 0 \text{ if and only if } r_\Sigma(\chi) = 0.$$  

We say $\chi$ is anticyclotomic if $\chi(\sigma c) = \chi(\sigma^{-1})$ for $\sigma \in \text{Gal}(K/K)$. If $\chi$ is further assumed to be anticyclotomic, it was shown in [BDF21] that $L_\Sigma(0,\chi) \neq 0$ if $r_\Sigma(\chi) = 0$ under Hypothesis (L). Our second result relates the rank one case of Conjecture $\dagger$ to the non-vanishing of the $L$-invariant $L_\chi$ for anticyclotomic characters $\chi$.

**Theorem B.** In addition to the validity of Hypothesis (L), we assume further that $\chi$ is a non-trivial anticyclotomic character. Then we have

$$\text{ord}_{s=0} L_\Sigma(s,\chi) = 1 \text{ if and only if } r_\Sigma(\chi) = 1 \text{ and } L_\chi \neq 0.$$  

1.3. The method. Although our results are mainly concerned with the first derivative of the cyclotomic $p$-adic $L$-function, the method crucially relies on the use of certain two-variable $p$-adic $L$-function, which we describe as follows. Denote by $\mathcal{L} : G_{ab}^F \rightarrow G_{ab}^K$ for the transfer map and fix a $p$-adic character $\varepsilon_\Sigma : \text{Gal}(K_{\Sigma_p}/K) \rightarrow \overline{\mathbb{Q}}_p^\times$ such that $\varepsilon_\Sigma \circ \mathcal{L}$ induces the $p$-adic cyclotomic character of $\text{Gal}(F_\infty/F)$. Let $\varepsilon_\Sigma$ denote the conjugate character $\overline{\varepsilon_\Sigma}$ and define the analytic function $L_\Sigma(\varepsilon_\Sigma(\chi)) : \mathbb{Z}_p^2 \rightarrow \overline{\mathbb{Q}}_p$ by

$$L_\Sigma(s,t,\chi) : = \varepsilon_\Sigma(s) \varepsilon_\Sigma(t) L_\Sigma(\chi), \quad (s,t) \in \mathbb{Z}_p^2.$$  

We prove the following result in Theorem $4.9$ and Proposition $6.6$. 

(1.3)
Theorem 1.1. There exists an analytic function $L^*_\Sigma(s, \chi)$ on $\mathbb{Z}_p - \{0\}$ such that

$$L_\Sigma(s, 0, \chi) = L^*_\Sigma(s, \chi) \prod_{\mathfrak{p} \in \Sigma_p} (1 - \chi(\mathfrak{p})\varepsilon^\chi_{\Sigma}(\mathfrak{F}_\mathfrak{p})).$$

Moreover, the following statements hold:

(i) If the Leopoldt conjecture for $F$ holds, then $L^*_\Sigma(s, \chi)$ is analytic at $s = 0$ if $\chi$ is non-trivial, and has a simple pole at $s = 0$ if $\chi = 1$ is the trivial character.

(ii) If Hypothesis (L) is valid, then $L^*_\Sigma(0, \chi) \neq 0$ for $\chi \neq 1$.

By definition, we have $L_\Sigma(s, s, \chi) = L\Sigma(s, \chi)$ for $s$ in a sufficiently small neighborhood of 0, and hence Theorem [A] directly follows from Theorem 1.1. We shall call $L^*_\Sigma(s, \chi)$ the improved $p$-adic $L$-function for $\chi$ in the sequel. The proof of Theorem [1.1] is briefly outlined as follows. Recall that the Katz $p$-adic $L$-function $L_\Sigma(\chi)$ for CM fields is obtained by the evaluation of Katz’s Eisenstein measure at CM points. To construct this improved $p$-adic $L$-function, we modify the Katz’s $p$-adic Eisenstein measure and construct a nice ordinary $p$-adic Eisenstein measure; then obtain the improved $p$-adic $L$-function $L^*_\Sigma(s, \chi)$ by evaluating this $p$-adic ordinary Eisenstein measure at CM points. The interpolation formula of $L^*_\Sigma(s, \chi)$ is proved via an explicit calculation of the toric period integral of Eisenstein series (Proposition 4.1), and then the relation between $L_\Sigma(\chi)$ and $L^*_\Sigma(s, \chi)$ can be seen immediately from the interpolation formula. The analyticity of $L^*_\Sigma(s, \chi)$ is determined by that of the constant term of our ordinary $p$-adic Eisenstein series, which is essentially the Deligne-Ribet $p$-adic $L$-function $L_p(1 - s, \chi^{-1})$ with $\chi^1 := \chi \circ \varphi$. We thus need the Leopoldt conjecture for $F$ to conclude the analyticity of $L^*_\Sigma(s, \chi)$ at $s = 0$ in some special cases (See Proposition 4.8). To see the non-vanishing of $L^*_\Sigma(0, \chi)$, we first observe that the $\Sigma$-Leopoldt conjecture is equivalent to the vanishing of the Bloch-Kato Selmer group $H^1_{\text{frob}}(F, \chi)$, consisting classes in $H^1(F, \chi)$ unramified outside $\Sigma_p$ (Lemma 2.1). On the other hand, we deduce a one-sided divisibility in the main conjecture for the improved $p$-adic $L$-function $L^*_\Sigma(s, \chi)$ from [Hsi14], which in turn implies that $L^*_\Sigma(0, \chi) \neq 0$ if $H^1_{\text{frob}}(F, \chi) = \{0\}$. This allows us to conclude the non-vanishing of $L^*_\Sigma(0, \chi)$ under the Hypothesis (L).

In general the value $L^*_\Sigma(0, \chi)$ is expected to be always nonzero whenever $\chi$ is non-trivial. When $K$ is an imaginary quadratic field, $L^*_\Sigma(s, \chi)$ is nothing but the $p$-adic $L$-function $L^*_\Sigma(s, \chi)$ introduced in [CH22] §3.3, and the value $L^*_\Sigma(0, \chi)$ equals the $p$-adic logarithm of Robert’s units by the $p$-adic Kronecker limit formula (cf. [RS87] Theorem 5.2, page 88], [CH22] (3.5)). In this case, the non-vanishing of $L^*_\Sigma(0, \chi)$ follows from the Baker-Brumer Theorem. Since the generalization of Katz’ $p$-adic Kronecker limit formula to CM fields is not available yet, the value $L^*_\Sigma(0, \chi)$ remains very mysterious. Nonetheless, Conjecture 4 leads us to propose the following

**Conjecture 4.** If $\chi \neq 1$, then we have

$$L^*_\Sigma(0, \chi) = \mathcal{R}_\Sigma(\chi) \prod_{\mathfrak{p} \in \Sigma_p} (1 - \chi(\mathfrak{p})\varepsilon^\chi(\mathfrak{F}_\mathfrak{p})).$$

Now we turn to the rank one case of Conjecture 4 for anticyclotomic characters. We prove the following first derivative formula of $L\Sigma(s, \chi)$ in Corollary 6.5. Combined with the non-vanishing of $L^*_\Sigma(0, \chi)$ in Theorem 1.1, this formula yields our Theorem 4.
Theorem 1.2. Let $\chi$ be a non-trivial anticyclotomic character. Suppose that the Hypothesis (L) holds. If $r_\Sigma(\chi) > 0$ and $\mathfrak{P}_1 \in \Sigma^{irr}_p$, then $L_\Sigma(0, \chi) = 0$, and

$$\frac{L_\Sigma(s, \chi)}{s} \bigg|_{s=0} = \mathcal{L}_\chi \cdot \mathcal{L}_\Sigma^* \cdot \left(1 - \frac{1}{\mathfrak{P}_1}\right).$$

When $r_\Sigma(\chi) > 1$, Theorem 1.2 amounts to the statement $L_\Sigma'(0, \chi) = 0$. Our proof of Theorem 1.2 is a vast generalization of the method in [CH22]. One of the key ingredients is to establish a leading term formula of the anticyclotomic $p$-adic $L$-function $L_\Sigma(s, -s, \chi)$, whose proof relies on (i) a refinement of the method of Hida and Tilouine [HT93] to produce non-trivial CM congruence by the $p$-adic Rankin-Selberg convolution, and (ii) the clever argument in [DKV18] of relating the leading term of the $U_p$-eigenvalues of $\Lambda$-adic generalized Hecke eigenforms to the $\mathcal{L}$-invariants. Let us sketch the idea of the proof. First note that since $\chi$ is anticyclotomic, we can choose a ray class character $\phi$ such that $\phi^{1-c} = \chi$. For a well-chosen such character $\phi$, we generalize the explicit CM congruence among elliptic modular forms in [CH22] to the Hilbert case and construct an explicit ordinary $\mathcal{W}[X]$-adic Hilbert cusp forms $\mathcal{H}$ in the sense of [Wils88 §1.2] such that

- $\mathcal{H}$ is a generalized Hecke eigenform modulo $X^{r+1}$ with $r = r_\Sigma(\chi)$;
- $\mathcal{H} \mod X^r$ is congruent to the Hida family $\theta_{\phi^e}$ of CM forms associated with $\phi^e$.

After an involved calculation in the Rankin-Selberg convolution (Proposition 5.3), we further find an explicit relation between $U_p$-eigenvalues of $\mathcal{H}$ and the following product of $p$-adic $L$-functions

$$L_\Sigma(s, -s, \chi) \cdot \frac{\zeta_{F,p}(1-s)}{L_\Sigma(s, \chi)} \cdot \frac{\zeta_{F,p}(1-s)}{L_\Sigma(s, 1)},$$

where $\zeta_{F,p}(s)$ is the $p$-adic Dedekind zeta function for $F$. We prove a special case of the $p$-adic Kronecker limit formula

$$\frac{L_\Sigma(s, 1)}{\zeta_{F,p}(1-s)} \bigg|_{s=0} = 2^{-d} \cdot h_{K/F},$$

in Proposition 4.8 and then apply the method of [DKV18] to show in Theorem 6.3 that

$$\text{ord}_{s=0} L_\Sigma(s, -s, \chi) \geq r_\Sigma(\chi)$$

and prove the following leading term formula of $L_\Sigma(s, -s, \chi)$ at $s = 0$

$$\frac{L_\Sigma(s, -s, \chi)}{s^{r_\Sigma(\chi)}} \bigg|_{s=0} = \mathcal{L}_\chi^{ac} \cdot \mathcal{L}_\Sigma^* \cdot \prod_{\mathfrak{P} \in \Sigma_p^{irr}} (1 - \mathfrak{P}),$$

where $\mathcal{L}_\chi^{ac}$ is the anticyclotomic $\mathcal{L}$-invariant (See Definition 2.2). We thus deduce in Corollary 6.5 the first derivative formula of $L_\Sigma(s, \chi)$ from the equation

$$\frac{L_\Sigma(s, \chi)}{s} \bigg|_{s=0} = 2 \cdot \frac{L_\Sigma(s, 0, \chi)}{s} \bigg|_{s=0} - \frac{L_\Sigma(s, -s, \chi)}{s} \bigg|_{s=0}$$

as well as the relation between the $\mathcal{L}$-invariants $\mathcal{L}_\chi$ and $\mathcal{L}_\chi^{ac}$.

Remark 1.3. The role of the $\Sigma$-Leopoldt conjecture in the research on trivial zeros of the Katz $p$-adic $L$-functions is fundamental. In the Appendix, we use Roy’s strong six exponential theorem to show that if $F$ is a real quadratic field where $p$ is split
and \( \chi \neq \chi^c \), then there exists a \( p \)-ordinary CM-type \( \Sigma \) such that the \( \Sigma \)-Leopoldt conjecture for \( \chi \) holds. In general, to the best of the authors’ knowledge, this conjecture is only known when \( H \) is an abelian extension of an imaginary quadratic field where \( p \) splits.

This paper is organized as follows. In \[2\] we recall the general definition of \( \mathcal{L} \)-invariants along any \( \mathbb{Z}_p \)-extension of \( K \). In \[3\] we review necessary background in the theory of Hilbert modular forms and Hilbert modular varieties. In \[4\] we construct a family of special Eisenstein series \( \mathbf{E}_\lambda \) indexed by certain Hecke characters \( \lambda \) of \( K \) via the adelic approach described in [Jac72, §19] and prove a Damerell’s formula in Theorem \[4.2\]. The desired \( p \)-adic Eisenstein measure is constructed in Proposition \[4.7\]. In \[5\], we apply the \( p \)-adic Rankin-Selberg method to construct the \( \Lambda \)-adic form \( \mathcal{H} \) in Definition \[5.2\] and state in Proposition \[5.3\] the explicit formula of the Rankin-Selberg convolution. In \[6\] we make use of the elegant ideas in [DKV18] to give a relation between the \( \Upsilon \)-eigenvalues of generalized Hecke eigenforms and the \( \mathcal{L} \)-invariant in Proposition \[6.1\] and prove the leading term formula of \( L(\Sigma(s, -s, \chi)) \). Finally in \[7\], we complete the proof of Proposition \[5.3\]. In the Appendix, we explain the connection between \( p \)-adic transcendental conjectures and the \( \Sigma \)-Leopoldt conjecture.

Acknowledgements. The first named author (A.B.) would like to thank D. Benois, M. Dimitrov, A. Maksoud and S.C Shih for numerous stimulating discussions. The second author (M.H.) thanks K. Buyukboduk for helpful comments on an early version of the manuscript.

Notation and conventions. Let \( \mathbb{Q}_p(1) \) denote the \( \mathbb{Q} \) representation of dimension 1 on which \( \mathbb{G}_m \) acts by the \( p \)-adic cyclotomic character. We follow the geometric convention: the Hodge-Tate weight of \( \mathbb{Q}_p(1) \) is \(-1\).

If \( L \) is a local or global field of characteristic zero, let \( \mathfrak{o}_L \) be the ring of integers of \( L \). Let \( G_L \) denote the absolute Galois group of \( L \) and let \( C_L := L^\times \) if \( L \) is local and \( C_L \) be the idele class group \( \mathbb{A}_L^\times /L^\times \) if \( L \) is global. Let \( \text{rec}_L : C_L \to \mathbb{G}_m^b \) be the geometrically normalized reciprocity law homomorphism.

Let \( L \) be a number field. If \( \mathfrak{q} \) is a prime ideal of \( \mathfrak{o}_L \) (resp. \( v \) is a place of \( L \)), let \( L_\mathfrak{q} \) (resp. \( L_v \)) be the completion of \( L \) at \( \mathfrak{q} \) (resp. \( v \)). Then \( \text{rec}_{L_\mathfrak{q}} : L_\mathfrak{q}^\times \to \mathbb{G}_m^b \) sends a uniformizer \( \varpi_\mathfrak{q} \) of \( \mathfrak{o}_{L_\mathfrak{q}} \) to the corresponding geometric Frobenius \( \text{Fr}_\mathfrak{q} \). If \( S \) is a finite set of prime ideals of \( \mathfrak{o}_L \), let \( L(S) \) be the maximal algebraic extension of \( L \) unramified outside \( S \) and let \( G_{L,S} = \text{Gal}(L(S)/L) \). For a fractional ideal \( \mathfrak{a} \) of a global field \( L \), we let \( \text{Fr}_\mathfrak{a} := \prod_\mathfrak{q} \text{Fr}_\mathfrak{q}^{n_\mathfrak{q}} \) if \( \mathfrak{a} \) has the prime ideal factorization \( \prod \mathfrak{q}^{n_\mathfrak{q}} \).

For any finite extension of global (or local) fields \( E/L \), we let \( N_{E/L} : E \to L \) be the norm map and let \( \mathfrak{o}_E \subset \mathfrak{o}_E \) denotes the absolute different ideal of \( E \).

2. The \( \mathcal{L} \)-invariants

2.1. The \( \Sigma \)-Leopoldt conjecture. Let \( S_p(K) \) be the set of primes of \( K \) lying above \( p \). Recall that \( \Sigma \subset \text{Hom}(K, \mathbb{C}) \) is a fixed CM type and \( \Sigma_p \subset S_p(K) \) is the subset of primes induced by \( \text{tr}_{L/L_p} \circ \Sigma \) (one has \( S_p(K) = \Sigma_p \bigcup \Sigma_p \)).

If \( A \) is a continuous \( G_K \)-module, then for any subgroup \( \mathcal{L} \subset \text{H}^1(K_p, A) = \bigoplus_{w|p} \text{H}^1(K_w, A) \), we let \( \text{H}^1(K, A) \) be the Selmer group of \( A \) with the local condition
\( \mathcal{L} \) defined by

\[
\mathcal{L}_a^0(K, A) = \ker \left\{ H^1(K, A) \to \prod_{w \mid \mathfrak{p}} H^1(I_w, A) \times \frac{H^1(K, A)}{\mathcal{L}} \right\}.
\]

For \( \mathfrak{p} \in S_p(K) \), let \( \mathcal{L}_0^0(K, A) = H^1(K, A) \) and \( \mathcal{L}_0^0(K, A) = \{0\} \). Denote by \( H^1_f(K, A) \) the finite part of \( H^1(K, A) \) in the sense of Bloch and Kato. Put

\[
\mathcal{L}_{a,b} = \prod_{\mathfrak{p} \in \Sigma_p} H^1_a(K, A) \oplus H^1_b(K, A) \text{ for } a, b \in \{0, f, 0\}.
\]

We set

\[
H^1_{a,b}(K, A) := \mathcal{L}_{a,b}(K, A).
\]

Let \( E \) be a finite extension of \( \mathbb{Q}_p \) and \( \chi : G_K \to E^\times \) be a non-trivial ray class character of \( K \). Set \( H \) be the finite extension of \( K \) cut out by \( \chi \) and \( C = \text{Gal}(H/K) \).

The Kummer map gives rise to an isomorphism

(2.1) \[
\phi_H^\chi[\xi] \to H^1_{f,f}(K, \chi^{-1}(1)),
\]

where \( \phi_H^\chi[\xi] \) is the \( \chi \)-isotypic component

\[
\phi_H^\chi[\xi] := \{ x \in E\phi_H^\chi \mid 1 \otimes g(x) = \chi(g) \otimes 1 \cdot x \text{ for all } g \in \text{Gal}(H/K) \}.
\]

Let

(2.2) \[
\Sigma_{\text{irr}}(\mathfrak{p}) = \{ \mathfrak{p} \in \Sigma_{\mathfrak{p}} \mid \chi(\mathfrak{p}) = 1 \}
\]

be the set of irregular primes for \( \chi \) in \( \Sigma_{\mathfrak{p}} \). Let \( d := [F : \mathbb{Q}] \) and \( r_{\Sigma}(\chi) = \#\Sigma_{\text{irr}}(\mathfrak{p}) \). By Dirichlet’s units Theorem and a standard calculation of local Galois cohomology groups, it is not difficult to see that

\[
\dim_E H^1_{f,0}(K, \chi^{-1}(1)) = d + r_{\Sigma}(\chi),
\]

\[
\dim_E H^1_{f,f}(K, \chi^{-1}(1)) = \sum_{w \in \Sigma_p} \dim_E H^1_f(K_w, \chi^{-1}(1)) = d,
\]

\[
\dim_E H^1_{0,0}(K, \chi^{-1}(1)) \leq r_{\Sigma}(\chi) + \dim H^1_{0,f}(K, \chi^{-1}(1)).
\]

Note that by definition, the subspace \( H^1_{0,f}(K, \chi^{-1}(1)) \) is actually the kernel of the \( p \)-adic regulator map

\[
\log_{\Sigma_p} : H^1_{f,f}(K, \chi^{-1}(1)) \cong \phi_H^\chi[\xi] \to \text{EY}_{H,\Sigma}, \quad x \mapsto \sum_{\sigma \in \Sigma_H} \log_p(\iota_p\sigma(x))\sigma;
\]

therefore the \( \Sigma \)-Leopoldt conjecture (Conjecture 2) can be rephrased as

\[
H^1_{0,f}(K, \chi^{-1}(1)) = \{0\}.
\]

**Lemma 2.1.** The \( \Sigma \)-Leopoldt conjecture for \( \chi \) is equivalent to

\[
(\Sigma\text{-Leo}) \quad H^1_{0,f}(K, \chi) = \ker \left\{ H^1(K, \chi) \to \bigoplus_{\Omega \in \Sigma_p} H^1(I_{\Omega, \chi}) \right\} = \{0\}.
\]

**Proof.** Since \( H^1_{f,f}(K, \chi) = \{0\} \) by the finiteness of the class numbers, by the Poitou-Tate exact sequence we have

\[
0 \to H^1_{0,f}(K, \chi^{-1}(1)) \to H^1_{f,f}(K, \chi^{-1}(1)) \to \bigoplus_{w \in \Sigma_p} H^1_f(K_w, \chi^{-1}(1)) \to H^1_{0,f}(K, \chi)^{\vee} \to 0,
\]
where $V^\vee = \text{Hom}_E(V, E)$ for a $E$-vector space $V$. We thus find that $\dim_E H^1_{(0,f)}(K, \chi) = \dim_E H^1_{(0,f)}(K, \chi^{-1}(1))$; the assertion follows.

2.2. The $\mathcal{L}$-invariants. We recall the general definition of $\mathcal{L}$-invariants for CM fields following [BETN19, Definition 5.2]. The validity of the $\Sigma$-Leopoldt conjecture for $\chi$ is assumed in this subsection. So we have $\dim_E H^1_{(0,0)}(K, \chi^{-1}(1)) = r_\Sigma(\chi)$ and the decomposition

$$H^1_{(f,0)}(K, \chi^{-1}(1)) = H^1_{(0,0)}(K, \chi^{-1}(1)) \bigoplus H^1_{(f,f)}(K, \chi^{-1}(1)).$$

We shall define the $\mathcal{L}$-invariant for $\chi$ to be certain $p$-adic regulator of the cohomology group $H^1_{(0,\emptyset)}(K, \chi^{-1}(1))$. For every $\Psi \in S_p(K)$, let $\langle ., . \rangle_\Psi : H^1(K_{\overline{\psi}}, \chi^{-1}(1)) \times H^1(K_{\overline{\psi}}, \chi) \to E$ be the local Tate pairing. For $\Psi \in \Sigma^\text{irr}_p$, $\chi|_{G_{K_{\overline{\psi}}}} = 1$, and we denote by $\text{ord}_{\overline{\psi}} \in H^1(K_{\overline{\psi}}, \chi) = \text{Hom}(K_{\overline{\psi}}^\times, E)$ the usual $\overline{\psi}$-adic valuation. Let $X_{\Sigma^\text{irr}_p}$ be the free abelian group generated by $\Psi$ with $\Psi \in \Sigma^\text{irr}_p$ and write $EX_{\Sigma^\text{irr}_p} = E \otimes_{\mathbb{Z}} X_{\Sigma^\text{irr}_p}$.

$$O_p : H^1_{(0,0)}(K, \chi^{-1}(1)) \to EX_{\Sigma^\text{irr}_p}, \quad O_p(x) = \sum_{\Psi \in \Sigma^\text{irr}_p} \langle \text{loc}_{\overline{\psi}}(x), \text{ord}_{\overline{\psi}} \rangle_{\overline{\psi}} \overline{\Psi}.$$ Note that $H^1_{(f,0)}(K, \chi^{-1}(1)) = H^1_{(0,0)}(K, \chi^{-1}(1))$ if $\Omega \notin \Sigma^\text{irr}_p$, so the $\Sigma$-Leopoldt conjecture implies that $O_p$ is injective and hence an isomorphism. On the other hand, for each $\psi \in H^1(K, E) = \text{Hom}(G_K, E)$, we put

$$L_p^\psi : H^1_{(0,0)}(K, \chi^{-1}(1)) \to EX_{\Sigma^\text{irr}_p}, \quad L_p^\psi(x) = \sum_{\Psi \in \Sigma^\text{irr}_p} \langle \text{loc}_{\overline{\psi}}(\psi), \text{loc}_{\overline{\psi}}(x) \rangle_{\overline{\psi}} \overline{\Psi}.$$ 

**Definition 2.2.** The $\mathcal{L}$-invariant $L_p^\psi$ associated with the ray class character $\chi$ along the additive homomorphism $\psi : G_K \to \mathfrak{O}_p$ is defined by

$$L_p^\psi := (-1)^{r_\Sigma(\chi)} \det(L_p^\psi \circ O_p^{-1}|EX_{\Sigma^\text{irr}_p}).$$

By definition, the cyclotomic $\mathcal{L}$-invariant $L_\chi := L_\chi^{\text{cyc}}$ with $\ell_\text{cyc} = \log_p \circ \langle \epsilon_\text{cyc} \rangle$.

We define the anticyclotomic $\mathcal{L}$-invariant $L_\chi^{\text{ac}}$ by

$$L_\chi^{\text{ac}} := L_\chi^{\text{ac}}, \quad \ell_\text{ac} := \log_p \circ \langle \epsilon_\text{ac} \rangle : G_K \to \mathfrak{O}_p.$$

3. Review of Hilbert modular varieties and Hilbert modular forms

We shall make use of the following notation frequently. If $M$ is an finitely generated abelian group, denote by $\hat{M}$ the profinite completion of $M$. If $E$ is a number field, denote by $\hat{E}$ the ring of integers of $E$. Let $\hat{E} = \hat{a} \otimes \mathbb{Z}$ be the group of finite ideles. If $a \in \hat{E}^\times$, the fractional ideal of $E$ generated by $a$ is defined to be $aE := a\hat{a} \cap E$, and if $a$ is an integral ideal of $E$, let $Na := \#(O_E/a)$ be the norm of $a$.

3.1. Hilbert Shimura varieties. Let $F$ be a totally real field and let $\mathfrak{a} = \mathfrak{a}_F$. Recall that a Hilbert-Blumenthal abelian variety by $\mathfrak{a}$ (or a HBAV for short) over a scheme $\mathcal{S}$ is an abelian scheme $A$ over $\mathcal{S}$ of relative dimension $d$ and equipped with an embedding of rings $\iota : \mathfrak{a} \to \text{End}_{\mathcal{S}}(A)$ such that $\text{Lie}(A)$ is an $\mathfrak{a} \otimes \mathfrak{O}_{\mathcal{S}}$-module locally free of rank 1.

Let $\mathfrak{c}$ be a fractional ideal of $F$ and let $\mathfrak{c}^+$ be the set of totally positive elements in $\mathfrak{c}$. The dual abelian scheme $A^\vee$ of $A$ has a canonical HBAV structure. Let $\mathcal{P}_A := \text{Hom}_{\mathfrak{a}}(A, A^\vee)_{\text{sym}}$ be the rank 1 projective $\mathfrak{a}$-module of symmetric $\mathfrak{a}$-linear
homomorphisms and $\mathcal{P}_A^+ \subset \mathcal{P}_A$ be the positive cone of polarizations. A $c$-polarization of $A$ is an $\mathfrak{o}$-linear map $\lambda : \mathfrak{c} \to \mathcal{P}_A$ sending $\mathfrak{c}_+$ to $\mathcal{P}_A^+$ such that the morphism
\[ \lambda : A \otimes_\mathfrak{o} \mathfrak{c} \simeq A^t, \quad x \otimes \alpha \mapsto \lambda(\alpha)x. \]
is an isomorphism of abelian schemes.

Let $N$ be a positive integer and let $\zeta_N = e^{\frac{2\pi i}{N}}$ be a fixed primitive $N$-th root of unity. Suppose that $N \geq 4$ is coprime to $p$ and the fractional ideal $\mathfrak{c}$ is coprime to $pN$. Consider the moduli functor $\mathcal{E}_{\mathfrak{c}, N, p^n}$ over $\mathbb{Z}[\frac{1}{N\Delta^2}, \zeta_N]$ classifying HBAV with $\mathfrak{c}$-polarizations and level $\Gamma(N) \cap \Gamma_1(p^n)$-structures. More precisely, for a basis scheme $S$ over $\mathbb{Z}[\frac{1}{N\Delta^2}, \zeta_N]$, $\mathcal{E}_{\mathfrak{c}, N, p^n}(S)$ is the set of isomorphism classes of the quadruple $(A, \lambda, \iota, \eta, \iota, \eta)$ such that the morphism
\[ A \to \mathbb{A} \] is an HBAV over $S$ and $\lambda$ is a $c$-polarization of $A$.

Let $A$ be the fractional ideal $\mathfrak{c}$ of unity. Suppose that $N \geq 4$ is coprime to $p$ and the fractional ideal $\mathfrak{c}$ is coprime to $pN$. Consider the moduli functor $\mathcal{E}_{\mathfrak{c}, N, p^n}$ over $\mathbb{Z}[\frac{1}{N\Delta^2}, \zeta_N]$ classifying HBAV with $\mathfrak{c}$-polarizations and level $\Gamma(N) \cap \Gamma_1(p^n)$-structures. More precisely, for a basis scheme $S$ over $\mathbb{Z}[\frac{1}{N\Delta^2}, \zeta_N]$, $\mathcal{E}_{\mathfrak{c}, N, p^n}(S)$ is the set of isomorphism classes of the quadruple $(A, \lambda, \iota, \eta, \iota, \eta)$ such that the morphism
\[ A \to \mathbb{A} \] is an HBAV over $S$ and $\lambda$ is a $c$-polarization of $A$.

The functor $\mathcal{E}_{\mathfrak{c}, N, p^n}$ is represented by a quasi-projective and smooth scheme $\mathfrak{M}(\mathfrak{c}, N, p^n)$ of relative dimension $[F : \mathbb{Q}]$ over $\mathbb{Z}[\frac{1}{N\Delta^2}, \zeta_N]$ ([Rap78], [Cha90] and [DP94]). We put
\[ \mathfrak{M}(\mathfrak{c}, N, p^n) = \varprojlim \mathfrak{M}(\mathfrak{c}, N, p^n). \]

### 3.2. Complex uniformization.

Now we recall the complex analytic structure of $\mathfrak{M}(\mathfrak{c}, N, p^n)(\mathbb{C})$. Let $\mathfrak{H}_F \subset F \otimes \mathbb{Q} \mathbb{C}$ be the upper half plane defined by
\[ \mathfrak{H}_F = \{ \tau = x + \sqrt{-1}y \in F \otimes \mathbb{C} \mid x \in F \otimes \mathbb{R}, y \in (F \otimes \mathbb{R})_+ \}. \]

To each $x = (\tau_x, g_x) \in \mathfrak{H}_F \times \text{GL}_2(\hat{F})$, we associate the quadruple $(A_x, \lambda_x, \eta_x, j_x)$ over $\mathbb{C}$ as follows: Let $V = Fe_1 \oplus Fe_2$ be the two-dimensional vector space over $F$ with the symplectic pairing
\[ \langle ae_1 + be_2, ce_1 + de_2 \rangle = \text{Tr}_{F/\mathbb{Q}}(bc - ad). \]

For $\tau \in \mathfrak{H}_F$, define the $\mathfrak{o}$-linear isomorphism $q_\tau : V \otimes \mathbb{Q} \mathbb{R} \simto F \otimes \mathbb{C}$ by
\[ q_\tau(xe_1 + ye_2) = x\tau + y, \quad (x, y, F \otimes \mathbb{R}). \]

Let $\mathbf{L}$ be the lattice $\mathfrak{a}e_1 \oplus \mathfrak{o}F^{-1}e_2$. For $g \in \text{GL}_2(\hat{F})$, put
\[ \mathbf{L}_g := (\mathfrak{L} \otimes \mathfrak{Z}) \mathbf{L}^{-1} \cap V. \]

Given $(\tau_x, g_x) \in \mathfrak{H}_F \times \text{GL}_2(\hat{F})$, we define the complex torus
\[ A_x(\mathbb{C}) = (F \otimes \mathbb{C})/L_x, \quad L_x = q_{\tau_x}(\mathbf{L}_{g_x}). \]

Let $\mathfrak{c}_x$ be the fractional ideal $\det g_x \mathfrak{o}$ generated by $\det g_x$. For $a \in \mathfrak{c}_x$, the pairing $E_a(\tau, w) := \text{Tr}_{F/\mathbb{Q}}(a \text{Im}(\tau)w)/\text{Im} \tau_x$ defines a Riemann form on $F \otimes \mathbb{C}$ if $a \in (\mathfrak{c}_x)_+$. Therefore $A_x(\mathbb{C})$ carries a structure of HBAV $A_x$ over $\mathbb{C}$ with the $\mathfrak{o}$-action induced by $q_{\tau_x}$. For $a \in \mathfrak{c}_x$, let $\lambda_x(a) : A_x \to A_x^t$ be the isogeny induced by $E_a(-, -)$, and
the map \( \lambda_x : a \mapsto \lambda_x(a) \) induces a \( \mathfrak{c}_x \)-polarization \( \lambda : (\mathfrak{c}_x, (\mathfrak{c}_x)_+) \to (\mathcal{P}_A, \mathcal{P}_A^+) \).

Define the level \( \Gamma(N) \cap \Gamma_1(p^n) \)-structures by

\[
\eta_x : (\mathfrak{o} \otimes N^{-1} \mathbb{Z} / \mathbb{Z}) \oplus (\mathfrak{d}_F^{-1} \otimes \mu_N) \simeq A_x[N],
\]

\[
(a \otimes N^{-1}, b \otimes \zeta_N) \mapsto \left( \frac{a}{N} e_1 g^{-1} + \frac{b}{N} e_2 g^{-1} \right) \pmod{L_x},
\]

\[
j_x : \mathfrak{d}_F^{-1} \otimes \mu_{p^n} \to A_x[p^n], \quad a \otimes \zeta_{p^n} \mapsto a/p^ne_2 g^{-1} \pmod{L_g}.
\]

This way \( (A_x, \lambda_x, \eta_x, j_x) \) is a HBAV with \( \mathfrak{c}_x \)-polarization \( \lambda_x \) and \( \Gamma(N) \cap \Gamma_1(p^n) \)-structures, and the isomorphism class \( [(A_x, \lambda_x, \eta_x, j_x)] \) gives rise to a point in \( \mathfrak{M}(\mathfrak{c}_x, N, p^n)(\mathbb{C}). \)

Fix an idele \( c \in \hat{F}(p^N) \times \) such that \( cc = c \) and put

\[
\text{GL}_2(\hat{F})^{(c)} = \left\{ g \in \text{GL}_2(\hat{F}) \mid \det g = c \right\}.
\]

For any open-compact subgroup in \( \text{GL}_2(\hat{F}) \), consider the complex Hilbert modular variety \( Sh(c, U)/C \) defined by

\[
Sh(c, U)(\mathbb{C}) := \text{SL}_2(F) \backslash \mathcal{G}_F \times \text{GL}_2(\hat{F})^{(c)}/(U \cap \text{SL}_2(\hat{F})).
\]

For any positive integer \( n \), put

\[
U_N(p^n) = \left\{ g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{GL}_2(\mathfrak{o}) \mid a, d \in 1 + p^n N \mathfrak{o}, \ c \in \mathfrak{c}p^n \mathfrak{d}_F, \ b \in N \mathfrak{d}_F^{-1} \right\}.
\]

Assume \( N \) is large enough such that

\[
U_N(1) \text{ is neat and } \det(U_N(1)) \cap \mathfrak{o}_+^\times \subset (U_N(1) \cap \mathfrak{o}_+^\times)^2.
\]

With the above condition, we see that the map

\[
\mathcal{G}_F \times \text{GL}_2(\hat{F})^{(c)} \to \mathfrak{M}(\mathfrak{c}, N, p^n)(\mathbb{C}), \quad x = (\tau_x, g_x) \mapsto [(A_x, \lambda_x, \eta_x, j_x)]
\]

induces an isomorphism

\[
Sh(c, U_N(p^n))(\mathbb{C}) \xrightarrow{\sim} \mathfrak{M}(\mathfrak{c}, N, p^n)(\mathbb{C}).
\]

3.3. Hilbert modular forms.

Geometric modular forms. Let \( k \) be an integer. Let \( R_0 \) be a \( \mathbb{Z}[\frac{1}{N \mathfrak{d}_F}, \zeta_N] \)-algebra. Let \( \mathcal{M}_k(\mathfrak{c}, N, p^n; R_0) \) be the space of geometric Hilbert modular forms of weight \( k \Sigma \) and level \( \Gamma(N) \cap \Gamma_1(p^n) \) defined over \( R_0 \). Recall that an element \( f \in \mathcal{M}_k(\mathfrak{c}, N, p^n; R_0) \) is a rule \( f \) which assigns a \( \mathfrak{c} \)-polarized quadruple \( (A, \lambda, \eta, j) \) of HBAV over a \( R_0 \)-algebra \( R \) together with an \( (\mathfrak{o} \otimes R) \)-basis \( \omega \) of \( H^0(A, \Omega^1_{A/R}) \) (or equivalently an isomorphism \( \omega^* : \text{Lie}(A) \simeq \mathfrak{d}_F^{-1} \otimes R) \) an element \( f(A, \lambda, \eta, j, \omega) \in R \) such that

\[
\begin{align*}
(M1) & \text{ the value } f(A, \lambda, \eta, j, \omega) \text{ only depends on the isomorphism class of } (A, \lambda, \eta, j, \omega), \\
(M2) & f(A, \lambda, \eta, j, \alpha^{-1}\omega) = \alpha^{k_2} \cdot f(A, \lambda, \eta, j, \omega) \text{ for any } \alpha \in (\mathfrak{o} \otimes R)^X, \\
(M3) & \text{ if } u : R \to R' \text{ is a homomorphism of } R_0 \text{-algebras, then } \\
& f((A, \lambda, \eta, j, \omega) \times_R R') = u(f(A, \lambda, \eta, j, \omega)).
\end{align*}
\]

We put

\[
\mathcal{M}_k(\mathfrak{c}, N; R_0) = \lim_{n} \mathcal{M}_k(\mathfrak{c}, N, p^n; R_0).
\]
We briefly recall the $q$-expansions of geometric modular forms. If $R$ is any ring and $M$ is a lattice in $F$, let $R[[M]]$ be the ring of all formal series
\[ \sum_{\beta \in M \cup \{0\}} a_{\beta} q^\beta, \quad a_{\beta} \in R. \]
We fix a set $\mathcal{C} = \{ l_1, \ldots, l_{[F:Q]} \}$ consisting of $[F:Q]$-linearly independent $Q$-linear forms $l_i : F \to Q$ such that $l_i(F_+) \subset Q_+$. Define $M_{c_+} = \{ x \in M \mid l_i(x) \geq 0, l_i \in \mathcal{C} \}$. Denote by $R[[M,\mathcal{C}]]$ the ring of all formal series $\sum_{\beta \in M_{c_+}} a_{\beta} q^\beta$. It is clear that $R[[M_{c_+}]] \subset R[[M,\mathcal{C}]]$ for any choice of $\mathcal{C}$. Let
\[ R((M,\mathcal{C})) := R[[M,\mathcal{C}]][U^{-1}], \quad U = \{ q^\beta \mid \beta \in M_{c_+} \}. \]
Let $(\alpha, \beta)$ be a pair of fractional ideals of $F$ such that $\alpha = ab^{-1}$. To any geometric modular form $f \in M_k(\mathcal{C},N;R_0)$, we can associate a power series $f|_{(\alpha,\beta)}(q) \in R_0((ab,\mathcal{C}))$ obtained by evaluating $f$ at the Tate HBAV Tate$_{ab}(q)$ together with a canonical differential over $\mathbb{Z}[\zeta_N][(ab,\mathcal{C})]$ (cf. [Kat78, 1.1 and (1.2.12)] and [Gor02, Chap 5, §2]). This power series $f|_{(\alpha,\beta)}$ is called the $q$-expansion of $f$ at the cusp $(\alpha, \beta)$.

**Classical modular forms.** Define the automorphy factor by
\[ J : \text{GL}_2(F \otimes \mathbb{R}) \times \mathcal{F}_F \to (F \otimes \mathbb{C})^\times, \quad J\left( \begin{pmatrix} a & b \\ c & d \end{pmatrix} \right) := cr + d. \]
For any idele $\mathfrak{c} \in \mathbb{F}^\times$ and an open-compact subgroup $U \subset \text{GL}_2(\mathbb{F})$, we let $M_k(\mathfrak{c},U)$ denote the space of classical modular forms of weight $k \Sigma$ and level $U$, which consists of holomorphic functions $f : \mathcal{F}_F \times \text{GL}_2(\mathbb{F})(\mathfrak{c}) \to \mathbb{C}$ such that
\[ f(\alpha(\tau,g)u) = J(\alpha,\tau)^k f(\tau,g) \quad \text{for} \quad \alpha \in \text{SL}_2(F); \ u \in U \cap \text{SL}_2(\mathbb{F}). \]
Letting $\mathfrak{c}$ be the idele such that $\mathfrak{c} \in \mathbb{F}^{(p^N)}$ with $\mathfrak{c}0 = \mathfrak{c}$, we put
\[ M_k(\mathfrak{c},N,p^n;\mathbb{C}) = M_k(\mathfrak{c},U_N(p^n)). \]
Give a pair of prime-to-$pN$ fractional ideals $(a,b)$ with $ab^{-1} = \mathfrak{c}$, choose $a,b \in \mathbb{F}^{(p^N)}$ with $\alpha a = a$ and $b \alpha = b$. Each $f \in M_k(\mathfrak{c},N,p^n;\mathbb{C})$ admits the Fourier expansion
\[ f(\tau, \begin{pmatrix} b^{-1} & 0 \\ 0 & a \end{pmatrix}) = c_0(f) + \sum_{\beta \in (N^{-1}ab)_+} c_\beta(f)e^{2\pi \sqrt{-1} \text{Tr}(\beta \tau)}, \]
where $\text{Tr} = \text{Tr}_{F/Q} : F \otimes \mathbb{C} \to \mathbb{C}$. The $q$-expansion of $f$ at the cusp $(a,b)$ is defined to be the power series
\[ f|_{(a,b)}(q) = c_0(f) + \sum_{\beta \in (N^{-1}ab)_+} c_\beta(f)q^\beta \in \mathbb{C}[[N^{-1}ab]_+]]. \]
If $R_0$ is a $\mathbb{Z}^\frac{1}{N\Sigma}$-algebra in $\mathbb{C}$, let
\[ M_k(\mathfrak{c},N,p^n;R_0) = \{ f \in M_k(\mathfrak{c},N,p^n;\mathbb{C}) \mid f|_{(a,c^{-1})}(q) \in R_0[[N^{-1}c^{-1}]_+] \}. \]
We put
\[ M_k(\mathfrak{c},N;R_0) = \lim_{n \to \infty} M_k(\mathfrak{c},N,p^n;R_0). \]
By [Rap78, Lemme 6.12] (or [Kat78, (1.6.3)]) and the $q$-expansion principle (cf. [Rap78, Theoreme 6.7] and [Kat78, (1.2.16)]), we have the isomorphism

\[
\mathcal{M}_k(c, N; R_0) \xrightarrow{\sim} \mathcal{M}_k(c, N; R_0), \quad f \mapsto f_{\text{an}}(x) = f(A_x, \eta_x, j_x, 2\pi \sqrt{-1} \omega^\text{an}_x).
\]

Here $\omega^\text{an}_x$ is given by the canonical isomorphism $\text{Lie}(A_x) \xrightarrow{\sim} \mathcal{O} \otimes \mathbb{C} = \mathcal{O}^{-1} \otimes \mathbb{C}$.

### 3.4. The Igusa tower and $p$-adic modular forms.

Let $R_0$ be a $p$-adic $\mathbb{Z}[\frac{1}{N\Delta_q}, \zeta_N]$-algebra, i.e., $R_0$ is a $\mathbb{Z}[\frac{1}{N\Delta_q}, \zeta_N]$-algebra and $R_0 = \varprojlim R_0/p^n R_0$. The Igusa tower $\text{Ig}(c, N)/R_0$ is the formal scheme

\[
\text{Ig}(c, N)/R_0 := \varprojlim_m \varprojlim_n \mathfrak{M}(c, N, p^n)/R_0/p^n R_0.
\]

We let $\widehat{\mathfrak{M}}^{\text{ord}}(c, N)$ be the ordinary locus (i.e., the locus where the Hasse invariant is invertible) of the formal completion of $\mathfrak{M}(c, N, p^n)/\mathbb{Z}_p$ along the special fiber. The natural projection $\pi_{\text{Ig}} : \text{Ig}(c, N)/\mathbb{Z}_p \to \widehat{\mathfrak{M}}^{\text{ord}}(c, N)$ given by forgetting the $\Gamma_1(p^\infty)$-level structure is Galois with group $(\mathfrak{o} \otimes \mathbb{Z}_p)^\times$.

The space $V(c, N, R_0)$ of $p$-adic modular forms of tame level $\Gamma(N)$ is defined to be the ring of formal functions on the Igusa tower $\text{Ig}(c, N)$. In other words, $V(c, N, R_0)$ is the ring of global sections of the structure sheaf of the formal scheme $\text{Ig}(c, N)/R_0$. To any $p$-adic modular form $f \in V(c, N, R_0)$ and $(a, b)$ fractional ideals with $ab^{-1} = c$, one can also associate a power series $f|_{(a, b)}$ in the $p$-adic completion $R_0((ab, \mathcal{O}))$ by evaluating at the Tate HBAV Tate_{a,b}(q) over $R_0((ab, \mathcal{O}))$.

Let $R$ be a $p$-adic $R_0$-algebra containing the Galois closure of $\mathfrak{o}$ in $\mathbb{Q}_p$. For any point $x = [(A_x, \lambda_x, \eta_x, j_x)] \in \text{Ig}(c, N)(R)$, the $\Gamma_1(p^\infty)$-level structure $j_x$ induces a canonical isomorphism $j_x : \mathcal{O}_F^{-1} \otimes \hat{\mathcal{G}}_{m/R} \to \hat{A}_x$ of formal groups, which in turn produces the isomorphism $(j_x)_* : \mathcal{O}_F^{-1} \otimes R \xrightarrow{\sim} \text{Lie}(A_x)$ of $(\mathfrak{o} \otimes R)$-modules by passage to Lie algebras. Define

\[
\pi_{\text{HT}}(x) := (j_x)_*^{-1} : \text{Lie}(A_x) \xrightarrow{\sim} \mathcal{O}^{-1} \otimes R
\]

to be the inverse of $(j_x)_*$ (cf. [Kat78, (1.10.11)]).

If $f \in \mathcal{M}_k(c, N; R_0)$ is a geometric modular form of level $\Gamma_1(p^\infty)$, we define the $p$-avatar $\hat{f} \in V(c, N, R_0)$ is defined as follows for any $x \in \text{Ig}(c, N)(R)$, define

\[
\hat{f}(x) := f(x, \pi_{\text{HT}}(x))
\]

which preserves the $q$-expansions (cf. [Kat78, Theorem (1.10.15)]).

### 3.5. CM points.

Let $K$ be a totally imaginary quadratic extension of $F$. Let $\mathfrak{d}_{K/F} = N_{K/F}(\mathfrak{D}_{K/F})$ be the relative discriminant of $K/F$. Suppose that $N$ is prime to $\mathfrak{d}_{K/F}$. Decompose $N\mathfrak{o}_K = \mathfrak{D}^+ \mathfrak{D}^-$, where $\mathfrak{D}^+$ is a product of primes split in $K$ and $\mathfrak{D}^-$ is a product of primes inert in $K$. By the approximation theorem, we can choose $\vartheta \in K$ such that

\[(d1)\ \ \bar{\vartheta} = -\vartheta \text{ and } \text{Im} \sigma(\vartheta) > 0 \text{ for all } \sigma \in \Sigma,
\]

\[(d2)\ \ \bar{c}(\vartheta_{\mathfrak{o}_K}) := \mathcal{O}^{-1}(2\mathfrak{d}_{K/F}^{-1}) \text{ is prime to } pN:\mathfrak{D}_{K/F}.
\]

Consider the isomorphism $q_{\vartheta} : V \xrightarrow{\sim} K$ defined by $q_{\vartheta}(a c_1 + b c_2) = a \vartheta + b$. Define the embedding $\iota : K \to M_2(F)$ by

\[
\iota(a \vartheta + b) = \begin{pmatrix} b & -\vartheta \bar{a} \\ a & b \end{pmatrix}.
\]
Note that
\[(3.8) \quad q_\sigma((0,1)\iota(\alpha)) = \alpha \quad \text{and} \quad q_\sigma(x)\alpha = q_\sigma(x\iota(\alpha)) \quad \text{for} \quad \alpha \in K \quad \text{and} \quad x \in V.\]

The CM type $\Sigma$ gives the isomorphism
\[i_\Sigma: K \otimes \mathbb{R} \xrightarrow{\sim} F \otimes \mathbb{C} \cong \mathbb{C}^\Sigma,\]
\[\alpha \in K \mapsto (\sigma(\alpha))_{\sigma \in \Sigma}.

Let $q_\varphi := i_\Sigma \circ q_\sigma: V \otimes \mathbb{Q} \xrightarrow{\sim} F \otimes \mathbb{C}$ with $\vartheta := i_\Sigma(\varphi) \in \mathfrak{H}_F$.

For a finite non-split place $v$ of $K/F$, let $\{1, e_v\}$ be an $o_v$-basis of $\sigma_K$. We further fix a decomposition $\mathfrak{M}^+ = \mathfrak{F} \mathfrak{F}_v$ with $(\mathfrak{F}, \mathfrak{F}_v) = 1$ and $\mathfrak{F} \subset \mathfrak{F}_v$. If $v \mid p\mathfrak{M}^+$ with $w \mid \Sigma_p \mathfrak{F}$, i.e. $w \in \Sigma_p$ or $w \mid \mathfrak{F}$, then we have $\sigma_K = o_v e_w \oplus o_v \mathfrak{F}_w$, where $e_w$ and $\mathfrak{F}_w$ are the idempotents of $\sigma_K$ corresponding to $w$ and $\mathfrak{F}$ respectively. Then $\{e_w, \mathfrak{F}_w\}$ is an $o_v$-basis of $\sigma_K$. In this case, we let $\vartheta_w \in F_v$ such that $\vartheta = -\vartheta_w \mathfrak{F}_w + \vartheta_w e_w$.

We shall also fix a finite idele $d_F = (d_{F_v}) \in F$ such that $d_F \sigma = \vartheta_F$. By condition (d2), we choose
\[d_{F_v} = \frac{2\vartheta}{\theta_v - \vartheta_v} \quad \text{if} \quad v \mid D_K / F_v, d_{F_v} = 2\vartheta_v \quad \text{if} \quad v \mid \mathfrak{M}^-, \quad \text{and} \quad d_{F_v} = -2\vartheta_w \quad \text{if} \quad w \mid \Sigma_p \mathfrak{F}.

Now we make a particular choice of a local basis $\{e_{1,v}, e_{2,v}\}$ of $K_v$ over $F_v$ for each finite place $v$ of $F$ such that $\sigma_K = o_v e_{1,v} \oplus o_v e_{2,v}$.

- If $v \not\mid pN$, $\{e_{1,v}, e_{2,v}\}$ is taken to be $\{\vartheta, 1\}$ for all but finitely many $v$.
- If $v \mid \mathfrak{M}^-$ is non-split, let $\{e_{1,v}, e_{2,v}\} = \{\vartheta_v, d_{F_v} \cdot 1\}$.
- If $v \mid p\mathfrak{M}^+$, let $\{e_{1,v}, e_{2,v}\} = \{\mathfrak{F}_v, d_{F_v} \cdot e_w\}$ with $w \mid \Sigma_p \mathfrak{F}$.

Let $\varsigma_v$ be the element in $\text{GL}_2(F_v)$ defined by
\[(3.9) \quad q_\sigma(e_{1,v}^{-1}) = e_{1,v}.

In view of our choices of $d_{F_v}$, one verifies that
\[\det \varsigma_v = 1 \iff \langle q_\sigma^{-1}(e_{2,v}), q_\sigma^{-1}(e_{1,v}) \rangle = 1 \quad \text{for} \quad v \mid pN.

In addition, the matrix representation of $\varsigma_v$ according to $\{e_1, e_2\}$ for $v \mid p\mathfrak{M}^+$ is given by
\[(3.10) \quad \varsigma_v = \begin{pmatrix} \frac{d_{F_v}}{2\vartheta_v} & -\frac{1}{2} \\ -\frac{1}{2} & \frac{1}{2\vartheta_v} \end{pmatrix} = \begin{pmatrix} -\vartheta_v & -\frac{1}{2} \\ 1 & \frac{1}{2\vartheta_v} \end{pmatrix} \quad \text{if} \quad v = w \mathfrak{F}_w \quad \text{and} \quad w \mid \Sigma_p \mathfrak{F}.

Let $h$ be the set of finite places of $F$, and put $\varsigma_h = \prod_{v \in h} \varsigma_v$. By definition, we have
\[(3.11) \quad q_\sigma((\mathcal{L} \otimes \mathcal{Z}) \cdot \varsigma_h^{-1}) = \hat{\sigma}_K.

**Definition 3.1.** Let $\mathfrak{A}$ be a fractional ideal of $K$ coprime to $pN$ and put
\[c(\mathfrak{A}) = c(\sigma_K)N(\mathfrak{A}).

Define the CM point
\[(3.12) \quad x(\mathfrak{A}) := [(\mathfrak{d}_\Sigma, (\iota(a)\varsigma_h)] = [(A_{\mathfrak{A}}, \lambda_\mathfrak{A}, \eta_\mathfrak{A}, j_\mathfrak{A})] \in \mathfrak{M}(c(\mathfrak{A}), N)(\mathbb{C}),
\]
where $a \in \hat{K}^{(oN)_x}$ is an idele with $aa_K = \mathfrak{A}$. By the theory of CM abelian varieties, the triple $(A_{\mathfrak{A}}, \lambda_\mathfrak{A}, \eta_\mathfrak{A})$ is defined over a number field $L$ ([Shi98, 18.6, 21.1]), which is defined in terms of a triple $(A_{\mathfrak{A}}, \lambda_{\mathfrak{A}}, \eta_{\mathfrak{A}})$ defined over $\mathcal{O}_L$ by a theorem of Serre-Tate. On the other hand, since the CM type $\Sigma$ is $p$-ordinary with respect to $t_p$, the reduction $A_{\mathfrak{A}} \otimes_{\mathcal{O}_L,t_p} \mathbb{F}_p$ is an ordinary abelian variety (cf. [Kat78, 5.1.27]), and hence the $\Gamma_g(p^\infty)$-level structure $j_\mathfrak{A}$ descends to a $\Gamma_\mathfrak{A}(p^\infty)$-level structure over
We conclude that the CM point \( x(\mathfrak{A}) \) can be descended to a \( \mathcal{W} \)-point \( x(\mathfrak{A}) \) in the Igusa tower \( \operatorname{Ig}(N, \varepsilon(\mathfrak{A}))(\mathcal{W}) \) for some finite extension \( \mathcal{W} \) of \( \hat{\mathbb{Z}}^\text{ur}_p \) ([Kat78, 5.1.19-20]).

4. Eisenstein series and the improved Katz \( p \)-adic \( L \)-functions

4.1. Notation and convention. Denote by \( \psi_{\mathbb{Q}} = \prod \psi_{\mathbb{Q}_v} : \mathbb{A}_{\mathbb{Q}} / \mathbb{Q} \to \mathbb{C}^\times \) the unique additive character with \( \psi_{\mathbb{R}}(x) = \exp(2\pi \sqrt{-1}x) \) and by \( |\cdot|_{\mathbb{Q}_v} = \prod |\cdot|_{\mathbb{Q}_v} : \mathbb{A}_{\mathbb{Q}_v} / \mathbb{Q}_v \to \mathbb{R}_+ \) the absolute value so that \( |\cdot|_{\mathbb{R}} \) is the usual absolute value on \( \mathbb{R} \).

Let \( E \) be a number field. Let \( \delta_E \) be the different of \( E / \mathbb{Q} \) and \( \Delta_E = N_{E/\mathbb{Q}}(\delta_E) \) be the absolute discriminant of \( E \). Let \( \psi_E := \psi_{\mathbb{Q}} \circ \operatorname{Tr}_{E/\mathbb{Q}} : \mathbb{A}_E \to \mathbb{C}^\times \). Denote by \( \cdot \) the absolute discriminant of \( E \). Let \( \psi_E := \psi_{\mathbb{Q}} \circ \operatorname{Tr}_{E/\mathbb{Q}} : \mathbb{A}_E \to \mathbb{C}^\times \). Denote by \( \cdot \) the absolute discriminant of \( E \). Let \( \psi_E := \psi_{\mathbb{Q}} \circ \operatorname{Tr}_{E/\mathbb{Q}} : \mathbb{A}_E \to \mathbb{C}^\times \). Denote by \( \cdot \) the absolute discriminant of \( E \). Let \( \psi_E := \psi_{\mathbb{Q}} \circ \operatorname{Tr}_{E/\mathbb{Q}} : \mathbb{A}_E \to \mathbb{C}^\times \). Denote by \( \cdot \) the absolute discriminant of \( E \).

Let \( \zeta_E(s) \) be the local \( L \)-factor and local epsilon factor of \( \chi_v \) in \([\text{Tat79}, 3.1]\). Let \( L(s, \chi) := \prod_v L(s, \chi_v) \) be the complete \( L \)-function of \( \chi \) and \( \varepsilon(s, \chi) := \prod_v \varepsilon(s, \chi_v) \) be the global epsilon factor \([\text{Tat79}, 3.5.1-2]\). Denote by \( L_{\text{fin}}(s, \chi) := \prod_{v < \infty} L(s, \chi_v) \) be the \( L \)-function without archimedean factors. If \( \chi = 1 \) is the trivial character of \( C_E^\times \), then we put

\[
\zeta_E(s) = L(s, 1_v); \quad \zeta_E(s) = L(s, 1).
\]

In particular,

\[
\zeta_{\mathbb{R}}(s) = \Gamma_{\mathbb{R}}(s) = \pi^{-\frac{s}{2}} \Gamma\left(\frac{s}{2}\right), \quad \zeta_{\mathbb{C}}(s) = \Gamma_{\mathbb{C}}(s) = 2(2\pi)^{-s} \Gamma(s).
\]

and \( \zeta_{\mathbb{Q}}(2) = \pi/6 \) with this definition.

Measures. Let \( v \) be a place of \( E \). If \( v \) is non-archimedean, let \( dx_v \) be the self-dual Haar measure on \( \sigma_{E_v} \) with respect to the additive character \( \psi_{E_v} \), i.e. \( dx_v \) is the measure such that \( \operatorname{vol}(\sigma_{E_v}, dx_v) = |\delta_{E_v}|^{\frac{1}{2}} \). If \( v \) is a real place, then \( dx_v \) is the Lebesgue measure. If \( v \) is a complex place, then \( dx_v \) is twice the Lebesgue measure. Let \( dx^\times \) be the Haar measure on \( E_v^\times \) defined by \( dx^\times = \zeta_E(1) |x_v|_{E_v}^{-1} dx_v \) (so \( \operatorname{vol}(\sigma_{E_v}, dx^\times) = |\delta_{E_v}|^{\frac{1}{2}} \)). The product measure \( dx = \prod_v dx_v \) is the Tamagawa measure on \( \mathbb{A}_E \). Denote by \( S(E_v) \) the space of Bruhat-Schwartz functions on \( E_v \). For \( \phi \in S(E_v) \), the Fourier transform \( \hat{\phi} \in S(E_v) \) is defined by

\[
\hat{\phi}(y) = \int_{E_v^\times} \phi(x_v) \psi_{E_v}(y x_v) dx_v.
\]

If \( \chi : E_v \to \mathbb{C}^\times \) is a continuous character, the Tate integral \( Z(\phi, \chi, s) \) is defined by

\[
Z(\phi, \chi, s) = \int_{E_v^\times} \phi(x_v) \chi(x_v) |x_v|_{E_v}^s dx^\times \quad (s \in \mathbb{C}).
\]
Characters. We fix an isomorphism $\tau_p : C \simeq \overline{Q}_p$ once and for all. Let $I_E$ be the set of all embeddings $E \to C$. Each $k \in \mathbb{Z}[I_E]$ shall be regarded as a character $k : (E \otimes \mathbb{R})^\times \to C^\times$ and $(E \otimes \mathbb{Q}_p)^\times \to \overline{Q}_p^\times$ via $\tau_p$. If $\chi$ is a $p$-adic character of $G_{E,S}$, we say $\chi$ is locally algebraic of weight $k \in \mathbb{Z}[I_E]$ if $\chi(\text{rec}_E(x)) = x^k$ for all $x \in (E \otimes \mathbb{Q}_p)^\times$ sufficiently close to 1. We shall also view $\chi$ as an idele class character via $\text{rec}_E$ and still denote by $\chi$ if there is no fear for confusion. In particular, a primitive ray class character $\chi$ modulo $\mathfrak{c}$ shall be identified with an idele class character $\chi$ of $E$ of conductor $\mathfrak{c}$. If $\chi : C_E \to C^\times$ is an idele class character of $F$ of level $n$, we put

$$\chi(s\mathcal{O}_E) := \chi(s) \text{ for } s \in \hat{E}^{(a)}.$$  

Therefore, 

$$\chi(q) := \chi(Fr_q) = \chi(q^{\omega_q}) \text{ for } q \not\in S.$$  

To an idele class character $\chi : C_E \to C^\times$ of infinity type $k \in \mathbb{Z}[I_E]$, i.e. $\chi_\infty(a_\infty) = a_\infty^k$, we can associate a $p$-adic idele class character $\hat{\chi} : C_E \to \overline{Z}_p^\times$ defined by

$$\hat{\chi}(a) = \chi(a)\tau_p(a^{-k})a_p^k.$$  

We call $\hat{\chi}$ the $p$-adic avatar of $\chi$. The $p$-adic character $\hat{\chi}$ factors through $\text{rec}_E : C_E \to G_E^{ab}$, and hence gives rise to a locally algebraic $p$-adic Galois character $\hat{\chi} : G_E \to \overline{Q}_p^\times$ of weight $k$.

Let $\omega : \text{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q}) \to C^\times$ be the character such that $\tau_p \circ \omega$ is the $p$-adic Teichmüller character. Let $\omega_E = \omega|_{\text{Gal}(E(\zeta_p)/E)}$. Viewed as an idele class character, we have $\omega_E = \omega \circ N_{E/\mathbb{Q}}$.

4.2. Generalities on Eisenstein series. Let $F$ be a totally real number field as before. Denote by $h$ the set of finite places of $F$. We shall identify $\Sigma$ with the set of infinite places of $F$. We recall a well-known construction of adelic Eisenstein series on $GL_2(A_F)$ in [Jac72 §19] (cf. [Bum97, p. 351]). Let $(\chi_1, \chi_2)$ be a pair of Hecke characters of $F^\times$, i.e. quasi-characters of $A_F^\times \setminus F^\times$. For each place $v$, let $I(\chi_1,v,\chi_2,s ; s)$ be the space of smooth (and $SO_2(\mathbb{R})$-finite if $v$ is archimedean) functions $f : GL_2(F_v) \to C$ such that

$$f \left( \begin{pmatrix} a & b \\ 0 & d \end{pmatrix} \right) = \chi_1(a)\chi_2(d) \frac{a^{s+\frac{1}{2}}}{d^{1-v}} f(g).$$  

Here $|\cdot|_v = |\cdot|_{F_v}$. Let $B$ be the upper triangular subgroup of $GL_2$. Define the adelic Eisenstein series $E_A(-, f) : GL_2(F) \setminus GL_2(A_F) \to C$ associated with $f$ by

$$E_A(g,f) := \sum_{\gamma \in B(F) \setminus GL_2(F)} f(\gamma g), \quad g \in GL_2(A_F),$$  

provided the sum is convergent. For $f = \otimes f_v \in I(\chi_1,\chi_2,s) := \otimes_v I(\chi_1,v,\chi_2,v; s)$ and $\beta \in F^\times$, define the local Whittaker function $W_\beta(-, f_v) : GL_2(F_v) \to C$ by

$$W_\beta(g_v, f_v) = \int_{F_v} f_v \left( \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \right) \left( \begin{pmatrix} 1 & x_v \\ 0 & 1 \end{pmatrix} \right) g_v \psi_{F_v}(-\beta x_v) dx_v.$$  

The global Whittaker function is defined by

$$W_\beta(g, f) = \prod_v W_\beta(g_v, f_v).$$
Let $f$ be a Hecke character of $(\Phi_4)^4$. Then we have Fourier expansion

$$E_A(g, f) = f(g) + Mf(g) + \sum_{\beta \in F^\times} W_\beta(g, f),$$

where $Mf(g)$ is obtained by the analytic continuation of the intertwining integral

$$Mf(g) = \int_{A_F} f\left(\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\right) g dx, \quad g \in \text{GL}_2(A_F)$$

(cf. [Bum97 (7.15)]).

4.3. The construction of adelic Eisenstein series. Let $\mathcal{C}$ be an integral ideal of $K$ such that $(\mathcal{C}, p\mathcal{O}_{K/F}) = 1$.

Decompose $\mathcal{C} = \mathcal{C}^+\mathcal{C}^-$, where $\mathcal{C}^+ = \mathfrak{F}\mathfrak{C}_c$ is a product of split primes in $K/F$ such that $(\mathfrak{F}, \mathfrak{C}_c) = 1$ and $\mathfrak{C}_c \subset \mathfrak{C}_c^c$, and $\mathcal{C}^-$ is a product of inert primes in $K/F$. Let $\lambda$ be a Hecke character of $K$ of infinity type $k\Sigma$, namely

$$\lambda_\infty(z) = \prod_{\sigma \in \Sigma} \sigma(z)^{k} \text{ for } z \in K^\times.$$

Let $\mathcal{C}_\lambda$ be the conductor of $\lambda$. We assume that

$$\mathcal{C}_\lambda = \mathcal{C} \prod_{\mathfrak{p} \in \Sigma_p} \mathfrak{p}^{e_\mathfrak{p}}.$$

In particular, $\lambda$ is unramified at primes in $\Sigma_p$.

For each place $v$ of $F$, we introduce some special Bruhat-Schwartz functions $\Phi_{\lambda,v} \in \mathcal{S}(F_v^2)$ as follows:

1. If $v \mid \infty$, then $\Phi_{\lambda,v}(x, y) = 2^{-k}(x + \sqrt{-1}y)^k e^{-\pi(x^2 + y^2)}$.
2. If $v \nmid p\mathfrak{C}$ is a finite place, let $\Phi_{\lambda,v}(x, y) = I_{\sigma_v}(x)I_{\delta_{2,v}}(y)$.
3. For $v \mid \mathcal{C}^-$ non-split in $K$, let

$$\Phi_{\lambda,v}(x, y) := I_{\sigma_x}(xe_{1,v} + ye_{2,v})\lambda(xe_{1,v} + ye_{2,v})^{-1}$$

4. If $v \nmid p\mathfrak{C}^+$ with $v = w\mathfrak{w}$ and $w \mid \Sigma_p\mathfrak{F}$, then

$$\Phi_{\lambda,v}(x, y) = \varphi_\mathfrak{w}(x)\varphi_\mathfrak{w}(y),$$

where $\varphi_w(y) = I_{\sigma_x}(y)\lambda_w(y)$ and

$$\varphi_\mathfrak{w}(x) = \begin{cases} I_{\sigma_x}(x) & \text{if } \mathfrak{w} \mid \mathfrak{F}_c, \\ I_{\sigma_x}(x)\lambda_w^{-1}(x) & \text{if } \mathfrak{w} \nmid \mathfrak{F}_c. \end{cases}$$

Let $\lambda_+: = \lambda|_{A_F^\times}$ be a Hecke character of $F^\times$. Define the function $f_{\Phi_{\lambda,v};s} : \text{GL}_2(F_v) \to \mathbb{C}$ by

$$f_{\Phi_{\lambda,v};s}(g) = |\det g|^v \int_{F_v^\times} \Phi_{\lambda,v}((0, t_v)g)\lambda_+(t_v)|t_v|_v^{2s} dt_v.$$

Let $f_{\Phi_{\lambda,s}} : \otimes_v f_{\Phi_{\lambda,v};s} \in I(1, \lambda_+^{-1}; s - \frac{1}{2})$ and define the Eisenstein series

$$E_{\lambda,s} : \text{GL}_2(F) \setminus \text{GL}_2(AF) \to \mathbb{C}, \quad E_{\lambda,s}(g) := E_A(g, f_{\Phi_{\lambda,s}}).$$
The analytic properties and the functional equation of this Eisenstein series have been studied in [Jac72, §19]. By the choice of our sections, we have

\[ E_{\lambda,s}(\alpha g u_\infty z) = E_{\lambda,s}(g) J(u_\infty, \sqrt{-1})^{-k \Sigma} \lambda_+^{-1}(z), \]

\[ \alpha \in \GL_2(F), \ u_\infty \in \SO_2(F \otimes \mathbb{R}), \ z \in \mathbb{A}_F^\times. \]

Here \( J \) is the automorphy factor in (3.3).

4.4. The evaluation of Eisenstein series at CM points. Let \( N \) be a sufficiently large power of \( N_K/\mathbb{Q}(\ell) \) so that the section \( f_{\Phi_{\lambda,s}} \) is invariant by \( U_N(p^n) \) for some \( n \gg 0 \). Define the classical Eisenstein series \( E_\lambda : \mathcal{H}_F \times \GL_2(\hat{F}) \to \mathbb{C} \) by

\[ E_\lambda(\tau, g_\theta) = E_{\lambda,s} \left( \begin{pmatrix} y & x \\ 0 & 1 \end{pmatrix}, g_\theta \right) \]

\[ (\tau = x + \sqrt{-1}y). \]

Let \( \ell \) be an integral ideal of \( F \) with \((\ell, pN) = 1 \) and \( \ell \in \hat{F}(pN) \times \) with \( \ell_0 = \ell \). From (4.6), we have

\[ E_{\lambda,\ell} := E_\lambda|_{\mathcal{H}_F \times \GL_2(\hat{F})(\ell)} \in M_k(\ell, N; \mathbb{C}). \]

We shall deduce an explicit Damerell’s formula, which relates the CM values of Eisenstein series to Hecke \( L \)-values for CM fields. We begin with the period integral of adelic Eisenstein series. Let

\[ \varsigma_\infty = \left( \begin{pmatrix} \Im \sigma(\theta) & 0 \\ 0 & 1 \end{pmatrix} \right)_{\sigma \in \Sigma} \in \GL_2(F \otimes \mathbb{Q} \mathbb{R}); \quad \varsigma := \varsigma_\infty \times \varsigma_\mathfrak{h} \in \GL_2(A_F). \]

Define the toric period integral of Eisenstein series by

\[ \ell_{K^\times}(E_{\lambda,s}) := \int_{K^\times \mathbb{A}_F^\times \backslash \mathbb{A}_K^\times} E_{\lambda,s}(\ell(z)\varsigma) \lambda(z) d^x z, \]

where \( d^x z \) is the quotient measure \( d^x z / d^x t \).

**Proposition 4.1.**

\[ \ell_{K^\times}(E_{\lambda,s}) = |\det(\varsigma)|^a_F \frac{(\sqrt{-1})^{k \Sigma} \gamma_s}{\sqrt{\Delta_K}} L(s, \lambda) \prod_{\ell \in \Sigma_F} (1 - \lambda(\mathfrak{P}^{-1})N \mathfrak{P}^{s-1}) \lambda_\mathfrak{P}(2\theta) \prod_{\ell \mid \mathfrak{S}} \lambda_{\mathfrak{S}}(2\theta). \]

**Proof.** By [Hsi12] page 1530

\[ \ell_{K^\times}(E_{\lambda,s}) = \prod_v \ell_{K^\times_v}(f_{\Phi_{\lambda_{v,s}}}, \lambda_v), \]

where \( \ell_{K^\times_v}(f_{\Phi_{\lambda_{v,s}}}, \lambda_v) \) is the local zeta integral

\[ \ell_{K^\times_v}(f_{\Phi_{\lambda_{v,s}}}, \lambda_v) = \int_{K^\times_v/F_{v^\times}} f_{\Phi_{\lambda_{v,s}}}(\ell(z)\varsigma_v) \lambda_v(z) d^x z \]

\[ = |\det(\varsigma_v)|^s_v \int_{K^\times_v} \Phi_{\lambda_{v}}((0, 1)\ell(z)\varsigma_v) \lambda_v(z) |z\mathfrak{P}_v| d^x z. \]

In what follows, we fix a place \( v \) and write \( z \) for \( z_v \). For \( v \mid \infty \),

\[ \ell_{K^\times_v}(f_{\Phi_{\lambda_{v,s}}}, \lambda_v) = |\det(\varsigma_v)|^s_v 2\pi^{-1} (2^{-1} \sqrt{-1})^k \int_0^{2\pi} \int_0^\infty r^{2(k+s)} e^{-\pi r^2} d^x r d\theta \]

\[ = |\det(\varsigma_v)|^s_v \cdot (\sqrt{-1})^k \cdot 2^s \Gamma_C(k + s). \]
If \( v \nmid \mathfrak{c} \mathbb{C} \), it follows from (3.8) and (3.11) that \( \Phi_{\lambda,s}(0,1)\zeta(z) = \mathbb{1}_{\mathfrak{o}_{K_v}}(z) \), so we have

\[
\ell_{K_v}(f_{\Phi_{\lambda,s}}, \lambda_v) = |\text{det}(\zeta_v)|^{\alpha} \int_{K_v} |\mathbb{1}_{\mathfrak{o}_{K_v}}(z)\lambda_v(z)\zeta(z)| \zeta_v(z) \, d\zeta_v(z).
\]

If \( v \mid \mathfrak{c}^- \), then

\[
\ell_{K_v}(f_{\Phi_{\lambda,s}}, \lambda_v) = |\text{det}(\zeta_v)|^{\alpha} \int_{K_v} |\mathbb{1}_{\mathfrak{o}_{K_v}}(z)\lambda_v(z)\zeta(z)| \zeta_v(z) \, d\zeta_v(z).
\]

If \( v \mid \mathfrak{c}^+ \) with \( v = w\mathfrak{m} \) and \( w \mid \mathfrak{f}_p \), then

\[
\ell_{K_v}(f_{\Phi_{\lambda,s}}, \lambda_v) = |\text{det}(\zeta_v)|^{\alpha} \lambda_v(\mathfrak{m}) \lambda_v(-\mathfrak{m})Z(\mathfrak{m}, \lambda_v(\mathfrak{m}), s)Z(\mathfrak{m}, \lambda_v(-\mathfrak{m}), s) \frac{L(s, \lambda_v)}{L(1 - s, \lambda_v^{-1})} \zeta(s, \lambda_v) \cdot L(s, \lambda_v) \cdot |\text{det}(\zeta_v)|^{\alpha} \mathfrak{f}_p^{\frac{1}{2}}(K_v).
\]

In the last equality, we have used the local functional equation of the Tate integrals. Now the proposition follows from the above calculations of local zeta integrals. \( \blacksquare \)

Let \( \text{Cl}_K^- := \text{Cl}(K) \cap \text{Cl}(F) \) and let \( h^- := \#(\text{Cl}_K^-) \). We fix a set \( \{\mathfrak{A}_1, \ldots, \mathfrak{A}_{h^-}\} \) of representatives for ideals \( \mathfrak{A}_i \) prime to \( \mathfrak{c} \mathbb{C} \mathbb{D}_{K/F} \). Let

\[
Q = \left[ \mathfrak{o}_K^\times : \mathfrak{c}_F^\times \right],
\]

where \( W \) is the torsion subgroup of \( K^\times \). Note that \( Q = 1 \) or \( 2 \).

**Corollary 4.2** (Damerell’s formula). Let \( \{x(\mathfrak{A}_1), \ldots, x(\mathfrak{A}_{h^-})\} \) be the CM points defined in Definition [3.7]. Then have

\[
\sum_{[\mathfrak{A}_1] \in \text{Cl}_K^-} E_{\lambda_\ell, x}(\mathfrak{A}_1)(x(\mathfrak{A}_1)) \lambda(\mathfrak{A}_1) \leq \frac{1}{2} \frac{|\mathfrak{o}_K^\times : \mathfrak{c}_F^\times|}{2d-1Q\sqrt{\Delta_F}} L(0, \lambda) \prod_{\mathfrak{p} \in \Sigma_{\mathfrak{f}}} (1 - \lambda(\mathfrak{p}^{-1}N\mathfrak{p}^{-1})L(2\mathfrak{p}) \cdot \prod_{\mathfrak{f} \in \Sigma_{\mathfrak{f}}} \mathfrak{f}_p(2\mathfrak{p}) \cdot \zeta(0, \lambda_{\mathfrak{f}})).
\]

**Proof.** By definition, \( x(\mathfrak{A}_1) = [(\vartheta_{\mathfrak{f}}, \nu(\mathfrak{a}_1)\zeta_{\mathfrak{h}})] \), where \( \mathfrak{a}_1 \in \mathbb{K}(\mathbb{C}) \times \mathfrak{a}_K^\times \) is an ideal with \( \mathfrak{a}_1 \mathfrak{o}_K = \mathfrak{A}_1 \). Let \( U_K := (K \otimes \mathbb{R})^\times \mathfrak{c}_K^\times \). There is an canonical isomorphism

\[
K^\times \mathfrak{a}_F^\times \setminus \mathfrak{A}_K^\times /U_K \simeq \text{Cl}_K^-, \quad a \mapsto a \mathfrak{o}_K.
\]

We have

\[
\sum_{[\mathfrak{A}_1] \in \text{Cl}_K^-} E_{\lambda_\ell, x}(\mathfrak{A}_1)(x(\mathfrak{A}_1)) \lambda(\mathfrak{A}_1) = \sum_{[\mathfrak{A}_1] \in \text{Cl}_K^-, \mathfrak{A}_1 \setminus \mathfrak{A}_K^\times /U_K} E_{\lambda_\ell, x}(\mathfrak{A}_1) \lambda(\mathfrak{A}_1)_{s=0} = \ell_{K^\times}(E_{\lambda_\ell, x})_{s=0} \cdot \frac{\#(\text{Cl}_K^-)}{\text{vol}(K^\times \mathfrak{a}_F^\times \setminus \mathfrak{A}_K^\times, d^\times \zeta)}.
\]

We have \( \text{vol}(K^\times \mathfrak{a}_F^\times \setminus \mathfrak{A}_K^\times, d^\times \zeta) = 2L(1, \tau_{K/F}) \). From the classical formulae

\[
\# \text{Cl}_K^- = \frac{2h_{K/F}}{Q}; \quad L(1, \tau_{K/F}) \sqrt{\frac{\Delta_K}{\Delta_F}} = \frac{2^{d-1}h_{K/F}}{|\mathfrak{o}_K^\times : \mathfrak{c}_F^\times|}.
\]

(4.8)
where $h_{K/F} = h_K/h_F$ is the relative class number, we obtain

\[
\frac{\#(C_{1})}{\text{vol}(K \times A_K^F \setminus A_K^F, d \times \tau)} \sqrt{\Delta_K} = \frac{\#(W)}{2^d \sqrt{\Delta_F}} = \frac{2}{Q} \cdot \left(\frac{q_K^0 : q_F^0}{q_K^0 : q_F^0}\right).
\]

The assertion follows from Proposition 4.1 and (4.9). \hfill \Box

4.5. The evaluation of $E_{\lambda, \tau}$ at CM points. We next consider the CM values of $p$-adic Eisenstein series constructed from $E_{\lambda, \tau}$ in 4.7.

**Proposition 4.3.** The $q$-expansion of $E_{\lambda, \tau}$ at the cusp $(\alpha, c^{-1})$ is given by

\[
E_{\lambda, \tau}(\alpha, c^{-1})(q) = c_0(E_{\lambda, \tau}) + \sum_{\beta \in (N^{-1}c^{-1})_+} c_{\beta}(E_{\lambda, \tau}) q^\beta,
\]

where $c_0(E_{\lambda, \tau}) = f_{\phi_{\lambda, s}}(1)|_{s=0}$ and

\[
c_{\beta}(E_{\lambda, \tau}) = (N\beta)^{k-1} \prod_{v \in \mathcal{h}} W_{\beta} \left( f_{\phi_{\lambda, s}}, \left( \begin{array}{cc} c & 0 \\ 0 & 1 \end{array} \right) \right) |_{s=0}.
\]

**Proof.** This is a standard argument. Let $f = f_{\phi_{\lambda, s}}$. By (4.4), $E_{\lambda, \tau}(\tau, \left( \begin{array}{cc} c & 0 \\ 0 & 1 \end{array} \right))$ is given by the series

\[
f \left( \begin{array}{cc} c & 0 \\ 0 & 1 \end{array} \right) |_{s=0} + Mf \left( \begin{array}{cc} c & 0 \\ 0 & 1 \end{array} \right) |_{s=0} + \sum_{\beta \in F^x} W_{\beta} \left( \left( \begin{array}{cc} y & x \\ 0 & 1 \end{array} \right) \left( \begin{array}{cc} c & 0 \\ 0 & 1 \end{array} \right) f \right) |_{s=0},
\]

where $\tau = x + \sqrt{-1}y$. Since $E_{\lambda}$ is right invariant by $U_N(p^n)$, we find that

\[
W_{\beta} \left( \left( \begin{array}{cc} c & 0 \\ 0 & 1 \end{array} \right), f \right) = 0 \text{ if } \beta \not\in N^{-1}c^{-1} \text{ by the equation } W_{\beta}(\left( \begin{array}{cc} 1 & x \\ 0 & 1 \end{array} \right) g, f) = \psi_f(\beta x) W_{\beta}(g, f).
\]

By the factorization of Whittaker functions, we obtain

\[
W_{\beta} \left( \left( \begin{array}{cc} y & x \\ 0 & 1 \end{array} \right) \left( \begin{array}{cc} c & 0 \\ 0 & 1 \end{array} \right), f \right) |_{s=0} = c_{\beta}(E_{\lambda, \tau})(N\beta)^{1-k}e^{2\pi\sqrt{-1}Tr(\beta x)} \prod_{\sigma \in \Sigma} W_{\beta} \left( \left( \begin{array}{cc} y\sigma & 0 \\ 0 & 1 \end{array} \right), f_{\phi_{\lambda, s}} \right) |_{s=0}.
\]

For $\sigma \in \Sigma$, an elementary calculation shows that

\[
W_{\beta} \left( \left( \begin{array}{cc} y\sigma & 0 \\ 0 & 1 \end{array} \right), f_{\phi_{\lambda, s}} \right) |_{s=0} = \Gamma(k)(-2\pi\sqrt{-1})^{-k}y_1^{-k} \int_{\mathbb{R}} e^{-2\pi\sqrt{-1}\sigma(\beta)yx} \frac{z^{-k}}{(z + \sqrt{-1})^k} dz = \sigma(\beta)^{k-1}e^{2\pi\sqrt{-1}\sigma(\beta)yx} \mathbb{R}_+(\sigma(\beta))
\]

by Cauchy’s integration formula. We thus obtain

\[
W_{\beta} \left( \left( \begin{array}{cc} y & x \\ 0 & 1 \end{array} \right) \left( \begin{array}{cc} c & 0 \\ 0 & 1 \end{array} \right), f \right) |_{s=0} = c_{\beta}(E_{\lambda, \tau})e^{2\pi\sqrt{-1}Tr(\beta x)} \mathbb{R}_+(\beta).
\]

On the other hand, the constant term is given by

\[
c_0(E_{\lambda, \tau}) = f_{\phi_{\lambda, s}} \left( \left( \begin{array}{cc} c & 0 \\ 0 & 1 \end{array} \right) \right) |_{s=0} + Mf_{\phi_{\lambda, s}} \left( \left( \begin{array}{cc} c & 0 \\ 0 & 1 \end{array} \right) \right) |_{s=0}.
\]

If $v$ is infinite, then $f_{\phi_{\lambda, s}}|_{s=0}$ belongs to the irreducible sub-representation in the induced representation $I(1, |\text{sgn}|^{k}; \frac{k-1}{2}) \otimes |\text{det}|^{-\frac{k}{2}}$; and hence $Mf_{\phi_{\lambda, s}}|_{s=0} = 0$. We thus obtain

\[
c_0(E_{\lambda, \tau}) = f_{\phi_{\lambda, s}} \left( \left( \begin{array}{cc} c & 0 \\ 0 & 1 \end{array} \right) \right) |_{s=0} = f_{\phi_{\lambda, s}}(1)|_{s=0}.
\]

The assertion follows. \hfill \Box
Define the fudge factor

\[(4.10) \quad Fdg(\lambda) := \prod_{\nu \mid o_K} \frac{\lambda_{\nu}(d_{F_{\nu}}^{-1}) |D_{F_{\nu}}|^{\frac{1}{d_{F_{\nu}}}} \varepsilon(0, \lambda_{\nu}, v)}{L(0, \lambda_{\nu}, v)} \begin{cases} 1 & \text{if } \nu = o_K, \\ 0 & \text{if } \nu \neq o_K. \end{cases}\]

By definition, \(Fdg(\lambda) = 1\) if \(\mathfrak{c} = (1)\) is the unit ideal.

**Lemma 4.4.** We have

\[c_0(E_{\lambda}, \mathfrak{c}) = Fdg(\lambda) \cdot \frac{1}{2^d} L_{\text{fin}}(1, \lambda_{+}^{-1}) \prod_{\nu \mid p} (1 - \lambda_{+}(p^{-1})\mathfrak{n}_{p}^{-1}).\]

**Proof.** If \(\nu \neq o_K\), then \(\Phi_{\lambda,v}(0, t) = 0\) and hence \(f_{\Phi_{\lambda,v},s}(1) = 0\) for \(v \mid o_K\). Now we suppose that \(\nu = o_K\). A direct calculation shows that

\[f_{\Phi_{\lambda,v},s}(1) = \begin{cases} 2^{-k} \sqrt{-1} \Gamma(s + k) \pi^{-s(s+k)} = 2^{-1} 2^s \pi \Gamma_{\mathfrak{c}}(s + k) & \text{if } v \mid \infty, \\ L(2s, \lambda_{+}) |D_{F_{v}}|^{\frac{1}{2}} & \text{if } v \mid p \mathfrak{c}, \\ \lambda_{\nu}^{-1}(d_{F_{v}}) |D_{F_{v}}|^{\frac{1}{2}} & \text{if } v \mid \mathfrak{c}, \\ \lambda_{+,v}(-1) \gamma(2s, \lambda_{+,v})^{-1} |D_{F_{v}}|^{\frac{1}{2}} & \text{if } v \mid p \mathfrak{c}. \end{cases}\]

Here \(\gamma(2s, \lambda_{+,v}) = \frac{L(1-2s, \lambda_{+,v}^{-1})}{L(2s, \lambda_{+,v})} \) is the \(\gamma\)-factor of \(\lambda_{+,v}\). We have

\[L(s, \lambda_{+}) = \Gamma_{\mathfrak{c}}(s + k + \epsilon)[F_{\lambda} : \mathfrak{c}] \cdot L_{\text{fin}}(s, \lambda_{+}),\]

where \(\epsilon = 0\) if \(k\) is even and \(\epsilon = 1\) if \(k\) is odd. By the functional equation of \(L(s, \lambda_{+})\) and \(\varepsilon(0, \lambda_{+,v}) = |D_{F_{v}}|^{-\frac{1}{2}}\) for \(v \mid p \mathfrak{c}\), we find that \(c_0(E_{\lambda}, \mathfrak{c}) = f_{\Phi_{\lambda,v,s}(1)}|_{s=0}\) equals

\[\left(\prod_{\nu} f_{\Phi_{\lambda,v,s}(1)}|_{s=0}\right) = \left(\frac{\sqrt{-1}^{k+\epsilon} \Gamma_{\mathfrak{c}}(k) \Gamma_{\mathfrak{c}}(1-k+\epsilon)}{2^{k+\epsilon} \Gamma(k+\epsilon)}\right)^{d} \prod_{\nu \mid p \mathfrak{c}} \lambda_{+,v}(-1) |D_{F_{v}}|^{\frac{1}{2}} \prod_{\nu \mid \mathfrak{c}} \varepsilon(0, \lambda_{+,v}) \frac{L(2s, \lambda_{+})|_{s=0}}{L(0, \lambda_{+,v})} = \frac{\sqrt{-1}^{k+\epsilon} \Gamma_{\mathfrak{c}}(k) \Gamma_{\mathfrak{c}}(1-k+\epsilon)}{\Gamma_{\mathfrak{c}}(k+\epsilon)} \prod_{\nu \mid \infty} \lambda_{v}(-1) Fdg(\lambda) \cdot L_{\text{fin}}(1, \lambda_{+}^{-1}) \prod_{\nu \mid p} (1 - \lambda_{+}^{-1}(p)\mathfrak{n}_{p}^{-1})\]

Now by reflection and duplicate formula for Gamma functions, we see that

\[\frac{\sqrt{-1}^{k+\epsilon} \Gamma_{\mathfrak{c}}(k) \Gamma_{\mathfrak{c}}(1-k+\epsilon)}{\Gamma_{\mathfrak{c}}(k+\epsilon)} = (-1)^k.\]

Now the lemma follows. \(\blacksquare\)

We write \(\lambda_{+} = \chi_{+} \cdot |^{k}\), where \(\chi_{+}\) is a ray class character of \(F\) modulo \(\mathfrak{c}_{\lambda} \cap F\). Let \(F_{\lambda_{+}}\) be the finite extension of \(F\) cut out by \(\chi_{+}\). We say \(\lambda_{+}\) is of type \(W\) if \(F_{\lambda_{+}}\) is contained in the cyclotomic \(\mathbb{Z}_{p}\)-extension \(F_{\infty}\) of \(F\). Take any prime \(q_{0} \mid p \mathfrak{c}\) of \(\mathfrak{c}\) such that its Frobenious \(F_{q_{0}}\) generates \(\text{Gal}(F_{\infty}/F)\). Let \(H_{q_{0}}(\lambda)\) be defined as

\[1 - \lambda_{+}(q_{0}) = 1 - \chi_{+}(q_{0})\mathfrak{n}_{q_{0}}^{-k} \neq 0\] if \(\mathfrak{c} = (1)\) and \(\lambda_{+}\) is of type \(W\) and \(H_{q_{0}}(\lambda) = 1\) otherwise. Note that \(H_{q_{0}}(\lambda)\) is a non-zero algebraic number.
Corollary 4.5. We have
\[ H_{q_0}(\lambda) \cdot E_{\lambda,c}|_{(s,\epsilon^{-1})} \in \mathbb{Z}(p)[[(N^{-1}e^{-1})_+]]. \]
In particular, \( E_{\lambda,c} \) descends to a geometric modular form \( E_{\lambda,c} \) in \( \mathcal{M}_k(c,N;\mathbb{Z}(p)) \otimes \mathbb{Q} \).

Proof. For \( \beta \in F^\times \), we put
\[ a_\beta^{(p)}(E_{\lambda,c}) := \prod_{v
ot| p} W_\beta(f_{\phi_{\lambda,s,v}}, s) \bigr|_{s=0}. \]
For each place \( v \not| p \), we see that \( |D_F|^{-\frac{1}{2}} \cdot f_{\phi_{\lambda,s,v}} \) is the function \( \phi_{\lambda,s,v} \) defined in \( \text{[HS14b]} \) §4.5. The explicit formula of \( a_\beta^{(p)}(E_{\lambda,c}) \) can be easily deduced from \( \text{[HS14b]} \) (4.9)], which in particular shows that \( a_\beta^{(p)}(E_{\lambda,c}) \) belongs to \( \sigma_L \) for some number field \( L \) unramified outside \( p \). On the other hand, for each \( v \mid p \),
\[ W_\beta(f_{\phi_{\lambda,s,v}}, 1) = \lambda_+,v(\beta) |_{\beta}^{-1} \cdot \Omega_{Fv} \cdot (\beta). \]
Let \( \hat{\lambda}_+ \) be the \( p \)-adic avatar of \( \lambda_+ \). So \( \hat{\lambda}_+((\beta)_p) = \lambda_+((\beta)_p) \beta^{\Sigma} \) for \( \beta \in F^\times \).
Therefore, from Proposition 4.3 we deduce that
(4.11) \[ c_\beta(E_{\lambda,c}) = a_\beta^{(p)}(E_{\lambda,c}) \hat{\lambda}_+((\beta)_p) \cdot N_{F/Q}(\beta)^{-1} |N_{F/Q}(\beta)|^{-1} \cdot \Omega_{Fv} \cdot \Omega_{Z(p)}(\beta) \in \mathbb{Z}(p). \]
By Lemma 4.4, we see that \( c_0(E_{\lambda,c}) = f_{\phi_{\lambda,s,v}}(1) \bigr|_{s=0} \) is given by a product of the value \( L_p(s,\chi_+^*) \) of the Deligne-Ribet \( p \)-adic \( L \)-function at \( s = 1 - k \) and the Fudge factor \( F_{dg}(\lambda) \in \mathbb{Z}(p) \). It is well-known that \( L_p(1-k,\chi_+^*) \in \mathbb{Z}(p) \) if \( \chi_+ \) is not of type \( W \) and in general \( (1-k,\chi_+^*) \cdot L_p(1-k,\chi_+^*) \in \mathbb{Z}(p) \) for any \( q \) away from the conductor of \( \chi_+ \). It follows that the product \( F_{dg}(\lambda)L_p(1-k,\chi_+^*) \in \mathbb{Z}(p) \) unless \( C = 1 \) and \( \chi_+ \) is of type \( W \), and hence \( H_{q_0}(\lambda) \cdot c_0(E_{\lambda,c}) \in \mathbb{Z}(p) \).

We let
\[ E_{\lambda,c} := \hat{E}_{\lambda,c} \in V(c,N;\mathbb{W}) \otimes \mathbb{Q}, \]
be the \( p \)-adic avatar of \( E_{\lambda,c} \) defined in \( \text{[3.7].} \) Let \( (\Omega_\infty,\Omega_\infty) \in (\sigma_p \otimes \mathbb{W})^\times \times (\mathbb{F} \otimes \mathbb{C})^\times \) be the canonical \( p \)-adic and complex period associated with the polarized CM abelian variety \( (\mathbb{F} \otimes \mathbb{C})/\mathbb{Z}_p(\sigma_K) \) \( \text{[HT94]} \) (4.4 a,b). It will be convenient to use the modified complex period defined by
(4.12) \[ \Omega := \Omega_\infty(1 \otimes \pi)^{-1}(- \text{Im } \vartheta_\Sigma) \in (\mathbb{F} \otimes \mathbb{C})^\times. \]

Proposition 4.6. We have
\[ \frac{1}{\Omega_p^{k_e}} \sum_{[\mathfrak{a}_i] \in \mathcal{C}(\mathfrak{a}_i)} \lambda(\mathfrak{a}_i) E_{\lambda,c}(\mathfrak{a}_i)(x(\mathfrak{a}_i)) = \frac{2\lambda((\mathbb{F} \otimes \mathbb{C})/\mathbb{Q}_p)}{Q} \prod_{\mathfrak{p} \mid \mathfrak{p} \mathfrak{p}} \lambda_{\mathbb{F}}(\mathfrak{p}) \cdot \beta_{\mathfrak{p}}^{\mathfrak{p} \mathfrak{p}} \cdot [\mathfrak{p}^\beta : \mathfrak{p}] \cdot \frac{1}{(\sqrt{-1})^{k_e}} \cdot \frac{L(0,\lambda)}{\Omega^{k_e}} \prod_{\mathfrak{p} \in \Sigma} (1 - \lambda(\mathfrak{p}^{-1})N_{\mathfrak{p}}^{-1}). \]

Proof. By \( \text{[HT93]} \) Theorem 1.2, we have
(4.12) \[ \frac{E_{\lambda,c}(\mathfrak{a}_i)}{\Omega_p^{k_e}} \left( \frac{2\pi \sqrt{-1}^{k_e}}{\Omega^{k_e}} \right) = \frac{E_{\lambda,c}(\mathfrak{a}_i)}{\Omega_p^{k_e}} = \frac{E_{\lambda,c}(\mathfrak{a}_i)}{\Omega_p^{k_e}} \mathbb{E}_{\lambda}(x(\mathfrak{a}_i)). \]
so we have
\[
\frac{1}{\Omega_p^{\Sigma+2j}} \sum_{[\mathfrak{A}_i] \in C_0} \lambda([\mathfrak{A}_i]) \mathcal{E}_\lambda(x([\mathfrak{A}_i])) = \frac{(2\pi \sqrt{-1})^{k\Sigma}}{\Omega_\infty} \sum_{[\mathfrak{A}_i] \in C_0} \lambda([\mathfrak{A}_i]) \mathcal{E}_\lambda(x([\mathfrak{A}_i])).
\]

Now the assertion follows immediately from Corollary 4.12 together with the equation \( \hat{\lambda}((2\theta)_{\Sigma_p}) = \lambda((2\theta)_{\Sigma_p}) (2\theta)^{k\Sigma} \) and the definition of the modified period \( \Omega \) in 4.12.

4.6. **The improved Katz \( p \)-adic \( L \)-functions for CM fields.** We let \( G_{\infty}(\mathcal{C}) \) denote the Galois group \( \text{Gal}(K(\mathcal{C}p^\infty)/K) \) of the ray class field \( K(\mathcal{C}p^\infty)/K \) modulo \( \mathcal{C}p^\infty \). Recall that Katz (\( \mathcal{C} = (1) \)) and Hida-Tilouine (\( \mathcal{C} \neq (1) \)) constructed an element \( L_\Sigma \in \mathcal{W}[G_{\infty}(\mathcal{C})] \), which is uniquely characterized by the following interpolation formula:

\[
\frac{\hat{\lambda}(L_\Sigma)}{\Omega_p^{k\Sigma+2j}} = \frac{[\sigma_K : \phi_p]}{2^d \Delta_F} \cdot \frac{(-1)^{k\Sigma}(2\pi)^{k+2j}}{\text{Im}(2\theta)^{k\Sigma+2j}} \cdot \lambda((2\theta)_{\Sigma_p})
\]

\( \times E_p(\lambda) L(0, \lambda) \prod_{i \in \mathcal{C}} (1 - \lambda(i)) \),

where

- \( \hat{\lambda} : G_{\infty}(\mathcal{C}) \to \mathcal{W}^\times \) is a locally algebraic character of weight \( k\Sigma + j(1 - c) \) critical at 0, namely either \( k > 0 \) and \( j \in \mathbb{Z}_{\geq 0}[\Sigma] \) or \( k \leq 1 \) and \( k\Sigma + j \in \mathbb{Z}_{>0}[\Sigma] \).

- \( E_p(\lambda) \) is the modified Euler factor defined by

\[
E_p(\lambda) = \prod_{\varphi \in \Sigma_p} \frac{(1 - \lambda(\varphi))(1 - \lambda(\varphi^{-1})N\varphi^{-1})}{\varepsilon(0, \lambda, \psi_{Kp})}.
\]

- \( L(s, \lambda) \) is the complete Hecke \( L \)-function associated with \( \lambda \) defined by

\[
L(s, \lambda) := \Gamma(1 + s + k\Sigma + j) L_{\text{fin}}(s, \lambda)
\]

(cf. [HT93 Theorem II]). Put

\[
\sigma_{2\theta} = \text{rec}_K((2\theta)_{\Sigma_p}) \in G_{\infty}(\mathcal{C}).
\]

Let \( \chi \) be a ray class character of \( K \) of conductor \( \mathcal{C} \). We let

\[
\pi_\chi : \mathcal{W}[G_{\infty}(\mathcal{C})] \to \mathcal{W}[G_{\infty}(1)]
\]

be the homomorphism defined by \( \gamma \mapsto \chi(\gamma) \langle \gamma |_{K(p^\infty)} \rangle \) and define the \( p \)-adic \( L \)-function \( L_\Sigma(\chi) \in \mathcal{W}[G_{\infty}(1)] \) associated with the branch character \( \chi \) by

\[
L_\Sigma(\chi) := \pi_\chi(L_\Sigma(\sigma_{2\theta})).
\]

The interpolation formula 4.13 can be rephrased as

\[
\frac{\hat{\nu}(L_\Sigma(\chi))}{\Omega_p^{k\Sigma+2j}} = \frac{[\sigma_K : \phi_p]}{2^d \Delta_F} \cdot \frac{1}{(\sqrt{-1})^{k\Sigma+j}} \cdot E_p(\chi) \cdot L(0, \chi) \cdot \frac{L(0, \chi)}{\Omega_p^{k\Sigma+2j}},
\]

where \( \hat{\nu} : G_{\infty}(1) \to \mathcal{W}^\times \) is a locally algebraic character of weight \( k\Sigma + j(1 - c) \) critical at 0 and \( \Omega \) is the modified period in 4.12. This form is in accordance with the conjectural shape of the \( p \)-adic \( L \)-functions for motives [Coa89 Conjecture A]. Let \( \Gamma := \text{Gal}(K_{\Sigma_p}/K) \). Put

\[
\chi^{\text{alg}} := \{ \hat{\nu} : \Gamma \to \mathcal{W}^\times \mid \hat{\nu} \text{ is locally algebraic of weight } k\Sigma, k \geq 2 \}.\]
Proposition 4.7. There exists a unique $p$-adic measure $d\mu_{\chi,\varepsilon}^{\text{Eis}}$ on $\Gamma$ valued in $V(N,\varepsilon;W)$ such that

$$\int_{\Gamma} \hat{\nu}(\sigma)d\mu_{\chi,\varepsilon}^{\text{Eis}}(\sigma) = H_{q_0}(\chi \nu) \cdot E_{\chi,\varepsilon}$$

for all $\hat{\nu} \in \mathcal{X}^{\text{alg}}$.

Proof. This is shown by a standard argument. First we note that since $\chi$ is assumed to be unramified outside $p$, $H_{q_0}(\chi \nu) = 1 - \chi(q_0)\hat{\nu}(q_0)$ if $\chi_\nu = 1$ and $1$ otherwise. The interpolation of the constant term $\hat{\nu} \mapsto H_{q_0}(\chi \nu) \cdot c_0(E_{\chi,\varepsilon}, \hat{\nu})$ is a direct consequence of the existence of Deligne-Ribet $p$-adic $L$-function. For $\beta \in F^\times$, it is shown in [Hsi14b (4.13)] that

$$H_{q_0}(\lambda) \cdot c_\beta(E_{\lambda, \varepsilon}) = \sum_j b_j \cdot \hat{\lambda}(a_j) \text{ for } b_j \in W,$$

where $a_j$ and $b_j$ depend on $\varepsilon$ and $\beta$ but do not rely on $\lambda$. Therefore, there exists a $W$-valued measure on $\Gamma$ interpolating $\beta$-th Fourier coefficient $H_{q_0}(\chi \nu) \cdot c_\beta(E_{\chi,\varepsilon}, \hat{\nu})$. Since $E_{\lambda, \varepsilon} = \tilde{E}_{\lambda, \varepsilon}$ share the same $q$-expansion with $E_{\lambda, \varepsilon}$ at $\langle \sigma, c^{-1} \rangle$, we thus obtain a $p$-adic measure $d\mu_{\chi,\varepsilon}^{\text{Eis}}(q)$ on $\Gamma$ valued in the ring $W\| (N^{-1}c^{-1})_+ \|$ such that the value of $d\mu_{\chi,\varepsilon}^{\text{Eis}}(q)$ at $\hat{\nu} \in \mathcal{X}^{\text{alg}}$ is the $q$-expansion of $H_{q_0}(\chi \nu) \cdot E_{\chi,\varepsilon}$. Since the set $\mathcal{X}^{\text{alg}}$ is dense in the space of continuous functions on $\Gamma$, we deduce that the measure $d\mu_{\chi,\varepsilon}^{\text{Eis}}(q)$ descends to a unique measure $d\mu_{\chi,\varepsilon}^{\text{Eis}}$ valued in $V(\varepsilon,N;W)$ such that the $q$-expansion of $d\mu_{\chi,\varepsilon}^{\text{Eis}}$ at the cusp $\langle \sigma, c^{-1} \rangle$ is $d\mu_{\chi,\varepsilon}^{\text{Eis}}(q)$ from the irreducibility of the Igusa tower $Ig(N,\varepsilon)$ due to Ribet.

Let $\mathcal{Y} : G_{F}^{ab} \to G_{K}^{ab}$ be the transfer map. Let $\varepsilon : \text{Gal}(K_{\Sigma_p}/K) \to W^\times$ be a $p$-adic character such that $\varepsilon \circ \mathcal{Y}|_{G_K} = \langle \varepsilon_{\text{cycl}} \rangle$. Let $\varepsilon_{\Sigma_p}(\sigma) := \varepsilon_{\Sigma_p}(\sigma c^{-1})$. Define the two-variable $p$-adic $L$-functions.

$$L_{\Sigma}(s,t,\chi) := \varepsilon_{\Sigma_p}^s \varepsilon_{\Sigma_p}^t \left( L_{\Sigma}(\chi) \right), \quad (s,t) \in Z_p^2.$$ 

Let $\psi$ be the idele class character of $K$ such that $\hat{\psi} = \varepsilon_{\Sigma}$. For $s \in Z_p$, put

$$E_{\chi,\varepsilon}(s) := \int_{\Gamma} \varepsilon_{\Sigma}(\sigma)^s d\mu_{\chi,\varepsilon}^{\text{Eis}}(\sigma) \cdot \begin{cases} 1 & \text{if } \varepsilon = 1 \text{ and } \chi^\varepsilon = 1, \\ 1 - \varepsilon_{\Sigma_p}(q_0)^{-1} & \text{otherwise.} \end{cases}$$ 

Then Proposition 4.6 and 4.14 implies that

$$\sum_{[\mathfrak{A}_i] \in \text{Cl}_{K_p}} E_{\chi,\varepsilon([\mathfrak{A}_i])(\chi(\mathfrak{A}_i))) \chi \varepsilon_{\Sigma_p}(\mathfrak{A}_i)$$

$$= C_{\chi} \cdot \varepsilon_{\Sigma}^{s}(\sigma_2 \mathfrak{F}_1) \cdot \frac{L_{\Sigma}(s,0,\chi)}{\prod_{q \in \Sigma_p} (1 - \chi \varepsilon_{\Sigma_p}(q))},$$

where

$$C_{\chi} := \frac{2\chi(\sigma_2 \mathfrak{F}_1)}{Q} \prod_{\varepsilon(0,\chi) \neq 0} \chi(\varepsilon)^{-1} \in Z_p^\times.$$ 

The following is a special case of $p$-adic Kronecker limit formula.
Proposition 4.8. Suppose that \((F, \text{Leo})\) holds. If \(\chi\) is unramified everywhere and \(\chi_+ = 1\), then we have
\[
\frac{2^d L_\Sigma(s, 0, \chi)}{\zeta_{F, p}(1 - s) \prod_{\varphi \in \Sigma_p} (1 - \chi(\overline{\varphi}) \varepsilon^e_\Sigma(\overline{\varphi})^s)} \bigg|_{s=0} = \begin{cases} h_{K/F} & \text{if } \chi = 1, \\ 0 & \text{if } \chi \not= 1. \end{cases}
\]

Proof. We have \(\mathfrak{C} = (1)\) since \(\chi\) is unramified everywhere. Put
\[
\mathcal{E}^*_{\chi,c}(s) := \frac{2^d \mathcal{E}_{\chi,c}(s)}{\zeta_{F, p}(1 - s)}.
\]
Note that \(\text{Fdg}(\chi) = 1\) if \(\mathfrak{C} = (1)\) and hence \(\mathcal{E}^*_{\chi,c}(s)|_{s = 0} = 1\) is the constant function by a result of Colmez \([\text{Col88}]\). By (4.15), we have
\[
\sum_{[\mathfrak{A}_i] \in \text{Cl}_K^-} \mathcal{E}^*_{\chi,c(\mathfrak{A}_i)}(s)(x(\mathfrak{A}_i)) \varepsilon^e_{\Sigma}(\mathfrak{A}_i) \chi(\mathfrak{A}_i) = \frac{2 \varepsilon_{\Sigma}(\sigma_2)^s}{Q} \frac{2^d L_\Sigma(s, 0, \chi)}{\zeta_{F, p}(1 - s) \prod_{\varphi \in \Sigma_p} (1 - \chi(\overline{\varphi}) \varepsilon^e_{\Sigma}(\overline{\varphi})^s)}
\]
Evaluating at \(s = 0\) of the above equation, we find that
\[
\frac{2}{Q} \frac{2^d L_\Sigma(s, 0, \chi)}{\zeta_{F, p}(1 - s) \prod_{\varphi \in \Sigma_p} (1 - \chi(\overline{\varphi}) \varepsilon^e_{\Sigma}(\overline{\varphi})^s)} \bigg|_{s=0} = \sum_{[\mathfrak{A}_i] \in \text{Cl}_K^-} \chi(\mathfrak{A}_i) = \begin{cases} \#(\text{Cl}_K^-) & \text{if } \chi = 1, \\ 0 & \text{if } \chi \not= 1. \end{cases}
\]
It follows from the formula \(\#(\text{Cl}_K^-) = 2 h_{K/F}/Q\).

Theorem 4.9. Suppose that \((F, \text{Leo})\) holds. If \(\chi \not= 1\), then there exists a analytic \(L\)-function \(L_\Sigma(\chi) \in \Lambda_K\) such that
\[
L_\Sigma(s, 0, \chi) = \mathcal{E}^e_{\Sigma}(L_\Sigma^*(\chi)) \prod_{\varphi \in \Sigma_p} (1 - \chi \varepsilon^e_{\Sigma}(\overline{\varphi})).
\]
We call \(L_\Sigma^*(s, \chi) := \mathcal{E}^e_{\Sigma}(L_\Sigma^*(\chi))\) the improved \(p\)-adic \(L\)-function.

Proof. For any \([\mathfrak{A}] \in \text{Cl}_K^-\), let \(d\mu_{\mathfrak{A}}\) be the bounded \(p\)-adic measure on \(\Gamma\) obtained by evaluating \(d\mu_{\mathcal{E}_{\chi,c}(\mathfrak{A})}\) at the CM point \(x(\mathfrak{A})\). Namely, \(d\mu_{\mathcal{E}_{\chi,c}}\) is characterized by the interpolation property
\[
\int_{\Gamma} \mathcal{E}_{\chi}(\sigma)^k d\mu_{\mathcal{E}_{\chi,c}}(\sigma) = \mathcal{E}_{\chi^k, c(\mathfrak{A})}(x(\mathfrak{A})).
\]
Let \(L_{\chi, \mathfrak{A}} \in \text{Frac}(\Lambda_K)\) be the corresponding element in the Iwasawa algebra of \(\Gamma\). Then \(L_{\chi, \mathfrak{A}} \in \Lambda_K\) unless \(\chi_+ = 1\) and \(\mathfrak{C} = (1)\). \((1 - [Fr_{q_0}])L_{\chi, \mathfrak{A}} \in \Lambda_K\) in general. Define
\[
(4.16) \quad L_{\Sigma}^*(\chi) := \left[ \sigma_2^{-1} Fr_{q_8} \right] L_{\chi, \mathfrak{A}} \cdot \varepsilon^e_{\Sigma}(\mathfrak{A}) \in \Lambda_K.
\]
One verifies that \(L_{\Sigma}^*(\chi)\) satisfies the desired interpolation property by (4.15) and that \(L_{\Sigma}^*(\chi) \in \Lambda_K\) if \(\chi \not= 1\) by Proposition 4.8.

5. \(p\)-adic Rankin-Selberg method for Hilbert modular forms

5.1. Hida families of Hilbert modular cusp forms. Let \(M_k(np, \xi)\) be the space of parallel weight \(k \geq 1\) Hilbert modular forms of level \(\Gamma_1(np)\) and Nebentypus \(\xi\), where \(n\) is a prime to \(p\) ideal of \(\mathfrak{a}_F\) and \(\xi\) is a finite order idele class character modulo
Let $F_\infty = F \mathbf{Q}_\infty$ be the cyclotomic $\mathbf{Z}_p$-extension of $F$ and let $\Lambda := \mathcal{W}[\text{Gal}(F_\infty/F)]$ be the Iwasawa algebra over $\mathcal{W}$ associated with $F_\infty/F$. We shall assume that $p$ is unramified in $F$ throughout. Let $\langle \varepsilon_{\text{cyc}} \rangle : \text{Gal}(F_\infty/F) \rightarrow \mathbf{Z}_p^\times$ be the $p$-adic cyclotomic character given by the composition $\text{Gal}(F_\infty/F) \rightarrow \text{Gal}(\mathbf{Q}_\infty/Q) \rightarrow \text{Gal}(\mathbf{Q}(\zeta_{p^n})/\mathbf{Q}) \simeq \mathbf{Z}_p^\times$, and for any integer $k$, let $\nu_k : \Lambda \rightarrow \mathbf{Z}_p$ be the natural morphism induced by $\langle \varepsilon_{\text{cyc}} \rangle^k : \text{Gal}(F_\infty/F) \rightarrow \mathbf{Z}_p^\times$. Let $h_+$ be the narrow class number of $F$. A $\Lambda$-adic modular form $\mathcal{F}$ of level $N$ and Nebentypus $\xi$ is a collection of elements

$$\{C_i(0, \mathcal{F}), i = 1, \ldots, h_+; \ C(a, \mathcal{F}), a \in \mathfrak{o} \text{ non-zero ideals} \} \subset \Lambda$$

such that for all but finitely many $k \geq 1$, there is a unique $\nu_k(\mathcal{F}) \in M_{k+1}(np, \xi \omega_F^k)$ whose associated Dirichlet series is

$$D(s, \nu_k(\mathcal{F})) = \sum_a \nu_k(C(a, \mathcal{F})) \mathfrak{n}a^{-s}$$

and whose constant terms are given by $C_i(0, \nu_k(\mathcal{F})) = \nu_k(C_i(0, \mathcal{F}))$. We denote by $\mathbf{M}(n, \xi)$ the space of $\Lambda$-adic modular forms of level $n$ and Nebentypus $\xi$ and by $\mathbf{S}(n, \xi)$ the subspace of $\Lambda$-adic cusp forms. Namely, $\mathbf{S}(n, \xi)$ is the subspace of $\mathbf{M}(n, \xi)$ consisting of $\mathcal{F} \in \mathbf{M}(n, \xi)$ with $\nu_k(\mathcal{F})$ is always a cusp form for all but finitely many $k \geq 1$. In particular, if $\mathcal{F} \in \mathbf{S}(n, \xi)$, then $C_i(0, \mathcal{F}) = 0$ for all $i = 1, \ldots, h_+$.

We have a natural action of the Hecke operators $\{T_q, U_q\}_{q | np, q | np}$ on $\mathbf{S}(n, \xi)$, which are compatible with the Hecke action on $S_{k+1}(np, \xi \omega_F^k)$ under the specialization $\mathbf{S}(n, \xi) \rightarrow S_{k+1}(np, \xi \omega_F^k)$ along $\nu_k$. For any integral ideal $b$ and $\mathcal{F} \in \mathbf{S}(n, \xi)$, define $V_b \mathcal{F} \in \mathbf{S}(nb, \xi)$ by $C(a, V_b \mathcal{F}) = C(ab^{-1}, \mathcal{F})$. Hida defined an ordinary projector $e^{\text{ord}} := \lim_{r \rightarrow \infty} (\prod_{p | b} U_p)^r$ on $\mathbf{S}(n, \xi)$. The $\Lambda$-module $\mathbf{S}^{\text{ord}}(n, \xi) = e^{\text{ord}}(\mathbf{S}(n, \xi))$ is the subspace of ordinary $\Lambda$-adic forms of tame level $n$ and Nebentypus $\xi$. For any finite flat $\Lambda$-algebra $R$, we denote by

$$\mathbf{S}^{\text{ord}}(n, \xi, R) := \mathbf{S}^{\text{ord}}(n, \xi) \otimes_{\Lambda} R$$

and let $\mathbf{T}(n, \xi, R) := R[\mathcal{T}_1, U_q|_{q | np, q | np}] \subset \text{End}_R \left( \mathbf{S}^{\text{ord}}(n, \xi, R) \right)$ be Hida’s big ordinary cuspidal Hecke algebra acting faithfully on $\mathbf{S}^{\text{ord}}(n, \xi, R)$. Hida’s control theorem [Hid88] (see also [Wil88]) yields:

- $\mathbf{S}^{\text{ord}}(n, \xi)$ is a finite free $\Lambda$-module.
- The specialization $\nu_k : \mathbf{S}^{\text{ord}}(n, \xi) \rightarrow S_{k+1}^{\text{ord}}(np, \xi \omega_F^k) := e^{\text{ord}}(S_{k+1}(np, \xi \omega_F^k))$ is surjective.
- $\mathbf{T}(n, \xi, \Lambda)$ is finite and flat over $\Lambda$.

5.2. **Hida families of theta series.** Let $K$ be a totally imaginary quadratic extension of $F$ as before and let $\tau_{K/F} : C_F \rightarrow \{\pm 1\}$ be the quadratic character associated
with $K/F$. To an idele class character $\psi : C_K \to \mathbf{C}^\times$ of infinity type $k\Sigma$ and conductor $\mathfrak{c}_\psi$ prime to $p$, we can associate a theta series $\theta_\psi \in S_{k+1}(N_{K/F}(\mathfrak{c}_\psi)\mathcal{O}_{K/F}, \xi)$ with $\xi := \cdot |_{\mathbf{A}_F}^{-1} \psi \tau_{K/F}$. The Fourier coefficients of $\theta_\psi$ are given by

$$C(n, \theta_\psi) = \sum_{\mathfrak{a} : \text{ideals of } \mathfrak{O}_K, \mathfrak{a} \mathfrak{p} = n, (\mathfrak{a}, \mathfrak{c}_\psi) = 1} \psi(\mathfrak{a}).$$

The $p$-stabilized newform $\theta_\psi^{(\Sigma_p)}$ associated with $\theta_\psi$ is defined by

$$C(n, \theta_\psi^{(\Sigma_p)}) = \sum_{\mathfrak{a} : \text{ideals of } \mathfrak{O}_K, \mathfrak{a} \mathfrak{p} = n, (\mathfrak{a}, \mathfrak{c}_\psi \Sigma_p) = 1} \psi(\mathfrak{a}).$$

In particular, if $p$ is a prime above $p$, then

$$C(p, \theta_\psi^{(\Sigma_p)}) = \psi(\mathfrak{p}) \quad \text{if } \mathfrak{p} \in \Sigma_p \text{ and } p\mathfrak{o}_K = \mathfrak{p}\mathfrak{o}_K.$$
5.3. A $\Lambda$-adic form of Eisenstein series. Let $\zeta_{F, p}(s)$ be the Deligne–Ribet $p$-adic $L$-function satisfying the interpolation property that for all positive integer $k$,

$$\zeta_{F, p}(1 - k) = \left( \prod_{p | p} \left( 1 - \omega_F(p)^k N\pi_{p}^{k-1} \right) \right) L(1 - k, \omega_F^\vee).$$

Let $\zeta_{F, p}^\vee \in \text{Frac} \Lambda$ be the element in Iwasawa algebra such that

$$\langle \varepsilon_{\text{cyc}} \rangle^k (\zeta_{F, p}^\vee) = \zeta_{F, p}(1 - k).$$

Let $q_0 | p$ be a prime of $\mathfrak{c}$ such that Fr$_{q_0}$ generates the Galois $\text{Gal}(F_{\infty} / F)$. Put

$$H_{q_0} = 1 - \text{Fr}_{q_0} \in \Lambda.$$

For each integral ideal $m$ of $F$ with $(m, p) = 1$, we let $E(m, 1)$ be the $\Lambda$-adic Eisenstein series with the $a$-th Fourier coefficient given by

$$C(a, E(m, 1)) = \sum_{m^{-1} < b < c \in (p, b) = 1} \text{N}b^{-1}[\text{Fr}_b]^{-1} \in \Lambda,$$

and the constant terms are given by

$$C_i(0, E(m, 1)) = 2^{-[F: Q]} \zeta_{F, p}^\vee$$

for $i = 1, \ldots, h_+$. This way we see that $H_{q_0} \cdot E(m, 1) \in M(m, \omega)$. Recall that if $l$ is a prime factor of $m$, then $U_l \in \text{End} M(m, \xi)$ is defined by

$$C(a, U_l F) = C(a, F), \quad C_i(0, U_l F) = C_i(0, F).$$

For any square-free divisor $m_0 | m$, we define

$$E(m, m_0) = \prod_{l | m_0} (1 - Nl^{-1} U_l) E(m, 1).$$

In particular,

$$C_i(0, E(m, m_0)) = 2^{-[F: Q]} \zeta_{F, p}^\vee \prod_{l | m_0} (1 - Nl^{-1}) \text{ for } i = 1, \ldots, h_+.$$

5.4. The Rankin-Selberg convolution. We call a ray class character $\chi$ anticyclotomic if $\chi(\sigma c) = \chi(\sigma^{-1})$, or equivalently $\chi \circ \mathcal{V} = 1$. When regarded as a Hecke character, $\chi$ is anticyclotomic if $\chi|_{\mathcal{A}_F} = 1$. Let $f$ be an integral ideal of $\mathfrak{c}$. Let $\chi$ be a primitive anticyclotomic character of $K$ modulo $f\mathfrak{d}_K$ with value in $W^\times$. Suppose that

$$(f, p\mathfrak{d}_{K/F}) = 1.$$

There exists a ray class character $\phi$ unramified at $p\mathfrak{d}_K / F$ such that

$$\chi = \phi^{1-c}$$

(cf. [Hd06] Lemma 5.31]). We are allowed to take a twist by a character of the form $\xi_1 \circ N_{K/F}$ with a ray class character $\xi_1$ of $F$. We say a character $\eta : K^\times_v \rightarrow C^\times$ is minimal if the conductor of $\eta$ is minimal among $\eta \cdot \xi_1 \circ N_{K_v / F_v}$, where $\xi_1$ runs over ray class characters of $F$. Now we fix an auxiliary prime $l_0 \mid pf\Delta_F$ of $\mathfrak{c}$ which is split in $K$. With the help of Lemma 5.1 below, we may assume $\phi$ satisfies the following minimal condition

$$(\text{min}) \quad \phi_v \text{ is minimal for all } v \in \mathfrak{h} \text{ except for } v = l_0.$$

by replacing $\phi$ by $\phi \cdot \xi_1 \circ N_{K/F}$ for a suitable ray class character $\xi_1$ of $F$.

**Lemma 5.1.** Let $S$ be a finite set of primes of $\mathfrak{o}$. Let $\xi_S$ be a finite order character of $\mathfrak{o}^\times_S := \prod_{v \in S} \mathfrak{o}^\times_v$. For any prime $\mathfrak{l} \not\in S$, there exists a finite order character $\xi : C_F \to \mathbb{C}^\times$ such that $\xi|_{\mathfrak{o}_S^\times} = \xi_S$ and $\xi$ is unramified outside $S \cup \{\mathfrak{l}\}$.

**Proof.** Let $U_F := (F \otimes \mathbb{R})^\times \prod_{v \in \mathfrak{m}} \mathfrak{o}_v^\times$ and let $U_F^{(l)} = \{x \in U_F | x_{\mathfrak{l}} = 1\}$ be a closed subgroup of $U_F$. We first extend $\xi_S$ to a character $\xi$ of $U_F^{(l)}$ so that $\xi$ is trivial on the $v$-component of $U_F^{(l)}$ for each $v \not\in S$. Since $\varphi \otimes U_F^{(l)} = \{1\}$, we can further extend $\xi$ to the product $\varphi \otimes U_F^{(l)}$ by requiring $\xi|_{\mathfrak{o}_S^\times} = 1$. Since the product $\varphi \otimes U_F^{(l)}$ is a closed subgroup in $U_F$, by Pontryagin duality $\xi$ can be further extended to $U_F$ which is trivial on $\varphi^\times$. The image of $U_F$ has finite index in $C_F = \mathbb{A}_F^\times/F^\times$, so we can extend $\xi$ to $C_F$ and obtain desired idele class character of finite order. ■

The conductor $\mathcal{C}_\varphi$ of $\varphi$ can be written as $\mathcal{C}_\varphi = \mathcal{C}_0 \mathcal{C}_l^0$ with $(\mathcal{C}_0, \mathcal{C}_l) = 1$. The minimal condition for $\varphi$ implies that $\mathcal{C}_0$ has a decomposition

$$
\mathcal{C}_0 = \mathcal{C}^+ \mathcal{C}^-,
$$
where $\mathcal{C}^-$ is only divisible by primes inert in $K$ and $\mathcal{C}^+$ is only divisible by primes split in $K$. Put

$$
\mathfrak{n} := \mathfrak{d}_{K/F} \mathcal{C}^+(c^-)^2 \mathfrak{l}_{\mathcal{C}_l}^0,\quad \mathfrak{m} := \mathfrak{d}_{K/F} \mathcal{C}^+ c^- \mathfrak{l}_{\mathcal{C}_l}^0 | \mathfrak{n},
$$
where $\mathcal{C}^+ = \mathcal{C}^+ \cap \mathfrak{p}$ and $\mathcal{C}^- = \mathcal{C}^- \cap \mathfrak{p}$. With the transfer map $\mathcal{V} : \Lambda \to \Lambda_K$, we define

$$
\mathcal{G}(\mathfrak{m}, \mathcal{I}_0) := \mathcal{V} \left( \frac{2^d \zeta_{F,p}(1)}{\zeta_{F,p}^2} \cdot \mathcal{E}(\mathfrak{m}, \mathcal{I}_0) \right).
$$
By definition, we have

$$
C_i(0, \mathcal{G}(\mathfrak{m}, \mathcal{I}_0)) = 1 \text{ for all } i = 1, \ldots, h_+;\quad C(a, \mathcal{G}(\mathfrak{m}, \mathcal{I}_0)) \in \Lambda_P,
$$
where $\Lambda_P$ is the localization of $\Lambda_K$ at the augmentation ideal $P$. Let $\theta^\circ_\varphi \in S_1(\mathfrak{n}, \varphi_+ \tau_{K/F})$ be the theta series of weight one defined by

$$
C(a, \theta^\circ_\varphi) = \sum_{(\mathfrak{a}, \mathfrak{e}_\varphi \Sigma^\varphi_{\mathfrak{e}} = 1,} \phi(\mathfrak{a}).
$$
In particular, if $\mathfrak{p}$ is a prime of $\mathfrak{o}_F$ above $p$ with $p \mathfrak{o}_K = \mathfrak{p} \mathfrak{P}$ and $\mathfrak{P} \in \Sigma_p$, then

$$
C(\mathfrak{p}, \theta^\circ_\varphi) = \begin{cases} 
\phi(\mathfrak{P}) & \text{if } \mathfrak{P} \not\in \Sigma^\text{irr}_p, \\
\phi(\mathfrak{P}) + \phi(\mathfrak{P})^{-1} & \text{if } \mathfrak{P} \in \Sigma^\text{irr}_p.
\end{cases}
$$
We shall consider the spectral decomposition of the product

$$
e_{\text{ord}}(\theta^\circ_\varphi \cdot \mathcal{G}(\mathfrak{m}, \mathcal{I}_0)) \in S^{\text{ord}}(\mathfrak{n}, \varphi_+ \tau_{F/F}, \Lambda_K).
$$
To be more precise, we denote for simplicity $\mathcal{S}$ for $S^{\text{ord}}(\mathfrak{n}, \varphi_+ \tau_{F/F}, \Lambda_K)$ and let $K$ be the field of fractions of $\Lambda_K$. Let $K'$ be a finite extension of $K$ containing all Fourier coefficients of normalized newforms in $S^{\text{ord}}(\varphi_+ \tau_{F/F}, K)$. Let $S_{K'}^+$ be the subspace of $S \otimes_{\Lambda_K} K'$ generated by

$$
\{V_{\mathfrak{a} \mathfrak{F}} | \mathfrak{F} \text{ a new form of level } \mathfrak{m} \text{ in } S \otimes_{\Lambda_K} K' \text{ and } \mathfrak{m} \mathfrak{b} | \mathfrak{n}, \mathfrak{F} \neq \theta^{\varphi_+} \theta^{\varphi^e}\}.$$

and let \( S^\perp_K = S^\perp_K \cap S \otimes_{\Lambda_K} K \). Then it follows from the theory of newforms \cite{Wil88} Prop. 1.5.2 that we have a spectral decomposition (a direct sum as Hecke modules)
\[(5.11) \quad S \otimes_{\Lambda_K} K := K \vartheta_\phi \oplus K \vartheta_{\phi^c} \oplus S^\perp_K.\]

Note that \( n \) is the tame conductor of \( \vartheta_\phi \) and \( \vartheta_{\phi^c} \), so \( S^\perp_K \) is the space interpolating the orthogonal complement of the subspace spanned by classical specializations of \( \vartheta_\phi \) and \( \vartheta_{\phi^c} \) under the Petersson inner product.

**Definition 5.2.** Let \( C(\phi, \phi^c) \) and \( C(\phi^c, \phi) \) be the unique elements in \( K \) such that
\[(5.12) \quad \mathcal{H} := \varepsilon_{\text{ord}}(\vartheta_\phi^c G(m, l_0)) - C(\phi, \phi^c) \cdot \vartheta_\phi - C(\phi^c, \phi) \cdot \vartheta_{\phi^c} \in S^\perp_K.\]

**Proposition 5.3.** With the ray class character \( \phi \) and the ideal \( m \) as above, we have
\[
\varepsilon_\Sigma^e(\phi, \phi) = \frac{1}{(Nm)^2} \cdot \frac{2^d \mathcal{L}_\Sigma(s, 0, 1) \mathcal{L}_\Sigma(s, 0, \chi)}{h_{K/F} \cdot \mathcal{L}_\Sigma(s, -s, \chi) \zeta_{F,p}(1 - s)} \times \prod_{\varphi \in \Sigma_p} (1 - \varepsilon^e_\Sigma(\varphi)) \cdot \text{Ex}_{l_0}(s),
\]
where
\[
\text{Ex}_{l_0}(s) = \frac{(1 - NL_0^{-1} \varepsilon^e_\Sigma (\mathcal{L}_0^{-1})) (1 - NL_0^{-1} \varepsilon^e_{\Phi} (\mathcal{L}_0^{-1})) (1 - NL_0^{-1} \chi \varepsilon^e_\Sigma (\mathcal{L}_0^{-1})) (1 - NL_0^{-1} \chi \varepsilon^e_{\Phi} (\mathcal{L}_0^{-1}))}{(1 - NL_0^{-1})^2 (1 - NL_0^{-1} \chi (\mathcal{L}_0) \varepsilon^e_\Sigma (\mathcal{L}_0^{-1})) (1 - NL_0^{-1} \chi (\mathcal{L}) \varepsilon^e_{\Phi} (\mathcal{L}_0^{-1}))}.
\]
In particular, \( C(\phi^c, \phi) \) and \( C(\phi, \phi^c) \) are both non-zero.

The proof of Proposition \ref{5.3} will be given in \S7.

6. Modular construction of cohomology classes and the applications to p-adic L-functions

6.1. Ribet’s construction of cohomology classes. Let \( S^\perp := S^\perp_K \cap (S \otimes_{\Lambda_K} \Lambda_P) \).

Let \( T^\perp \subset \text{End}_{\Lambda_K}(S^\perp) \) be the image of the Hecke algebra \( T = T(n, \phi, \tau_{k/(q, \Lambda)}) \) restricted to \( S^\perp \). The computation of \cite{DKV18} \S5 provides a general method to compute the \( Z^p \)-invariant \( Z^\psi \) of \( \chi \) along an additive homomorphism \( \psi : G_{K,S} \to \mathbb{Q}_p \)
introduced in Definition \ref{2.2} if one can construct an explicit Hecke eigensystem of \( T^\perp \) valued in some artinian local ring \( W \).

Fix a topological generator \( \gamma_0 \in \text{Gal}(K_{\Sigma_p}/K) \simeq \mathbb{Z}_p \). We have \( \Lambda_K = W[[X]] \) with the variable
\[(6.1) \quad X := ([\gamma_0] - 1)/\log_p(\varepsilon_\Sigma(\gamma_0)) \in \Lambda_K.
\]

Let \( S \) be a set of prime divisors of \( pm \). For any finite extension \( L/F \), denote by \( G_{L,S} \) the Galois group of the algebraic extension of \( L \) unramified outside primes above \( S \). Let \( r := r_{\Sigma}(\chi) \). Suppose that \( r > 0 \). Let \( \Sigma^\text{irr} = \{ \mathfrak{p}_1, \ldots, \mathfrak{p}_r \} \) and put
\[
\tilde{\Lambda} := \Lambda_P[y, e_1, e_2, \ldots, e_r].
\]

For \( n \geq m \geq 1, z \in \Lambda_P \), and \( b \in \mathbb{Q}_p \), let \( I_{n,m,z,b} \) be the ideal of \( \tilde{\Lambda} \) defined by
\[
I_{n,m,z,b} := (Y^{n+1}, X(Y - Y), X^m - z Y^m, X e_i, Y e_i, e_i^2, e_i, \ldots, e_r + b Y^n).
\]

We consider the artinian local ring \( W = \tilde{\Lambda}/I_{n,m,z,b} \) with the maximal ideal \( m_W = (X, Y, e_i) \). The following proposition is extracted from \cite{DKV18} \S4 and \S5 with some modifications to our setting. Recall that \( \Psi : G_{K,\Sigma} \to \Lambda_K^\times \) is the universal character defined in \ref{5.3}. 

Proposition 6.1. Let \( \lambda : T^\perp \to W \) be a surjective \( \Lambda_K \)-algebra homomorphism with \( n \geq 0 \) such that for primes \( \mathfrak{l} \notin S \),

\[
\lambda(T_l) \equiv \phi(\mathcal{L}) + \phi(\mathcal{L}) \pmod{m_W} \quad \text{if } \mathfrak{l} = \mathfrak{M} \text{ split in } K,
\]

\[
\lambda(T_l) \equiv 0 \pmod{m_W} \quad \text{if } \mathfrak{l} \text{ is inert in } K,
\]

and for \( \mathfrak{p} = \mathfrak{P}/\mathfrak{p} \) with \( \mathfrak{P} \in \Sigma_p \),

\[
\lambda(U_p) = \phi^c(\mathfrak{P}) \quad \text{if } \mathfrak{P} \notin \Sigma_{\text{irr}},
\]

\[
\lambda(U_p) = \phi(\mathfrak{P}) + (1 + \varepsilon_l) \quad \text{if } \mathfrak{P} = \mathfrak{P}_l \in \Sigma_{\text{irr}}.
\]

Suppose that there exists a character \( \tilde{\Psi} : G_{K,S} \to W^\times \) and an element \( Z \in (X,Y) \) such that

(i) \( \tilde{\Psi} \equiv \Psi + Z \psi (\text{mod } Zm_W) \) for some additive character \( \psi : G_{K,S} \to W \),

(ii) \( \lambda(T_l) = \phi(\mathfrak{P}(\text{Fr}_l)) + \phi(\mathfrak{P}(\text{Fr}_l)) \) for \( \mathfrak{l} = \mathfrak{M} \) split in \( K \) with \( \mathfrak{l} \notin S \).

If \( \Sigma\text{-Leop} \) holds, then we have the equation

\[
bY^n + Z^cZ^r \equiv 0 \pmod{Z^r m_W}.
\]

Proof. Let \( \Lambda^I \supset \Lambda_P \) be the local ring of rigid analytic functions around \( X = 0 \), i.e.

\[
\Lambda^I = \left\{ \sum_{n=0}^{\infty} a_n X^n \in \overline{\mathbb{Q}}_p[[X]] \left| \text{there exist } t > 0 \text{ such that } \lim_{n \to \infty} |a_n| t^n = 0 \right. \right\}.
\]

Let \( T^I = T^\perp \otimes_{\Lambda_K} \Lambda^I \) be a finite \( \Lambda^I \)-algebra. Let \( \tilde{\Lambda}^I = \tilde{\Lambda} \otimes_{\Lambda_P} \Lambda^I \) and \( I = I_{n,m,z,b} \tilde{\Lambda}^I \). Let \( I = \text{Ker } \lambda \) be the kernel of the map \( \lambda : T^I \to \tilde{\Lambda}^I/I \). Note that \( T^I/I \simeq \tilde{\Lambda}^I/I \) is a local ring. Let \( m_R \) be the maximal ideal of \( T^I \) containing \( I \) and denote by \( R = T^I(m_R) \) the localization of \( T^I \) at \( m_R \). Then \( R \) is a finite flat \( \Lambda^I \)-algebra. In addition, \( R \) is reduced for \( n \) is the tame conductor of \( \theta_\phi \). The theory of pseudo-characters produces a continuous irreducible Galois representation \( \rho_{\lambda} : G_{F,S} \to \text{GL}_2(R) \) such that \( \text{Tr } \rho_{\lambda}(\text{Fr}_l) = T_l \in R \) for any prime \( l \notin S \) and the assumption (ii) implies that

\[
\text{Tr } \rho_{\lambda}|_{G_{K,S}} \equiv \phi \tilde{\Psi} + \phi^c \tilde{\Psi}^c \pmod{IR}.
\]

The fractional field \( \text{Frac } R \) is isomorphic to a product of fields

\[
\text{Frac } R = \prod_{i=1}^{t} L_{\mathcal{H}_i},
\]

and each field \( L_{\mathcal{H}_i} \) is a finite extension of \( \Lambda^I \) and corresponds to a cuspidal Hida family \( \mathcal{H}_i \). For \( i = 1, \ldots, t \), let \( \pi_i : \text{Frac } R \to L_{\mathcal{H}_i} \) be the natural projection map. Then \( \rho_{\mathcal{H}_i} := \rho_{\lambda} \circ \pi_i : G_{F,S} \to \text{GL}_2(L_{\mathcal{H}_i}) \) is the Galois representation associated with \( \mathcal{H}_i \). We claim the restriction \( \rho_{\mathcal{H}_i}|_{G_{K,S}} \) is still irreducible. Otherwise \( \mathcal{H}_i \) would be the Hida family \( \theta_{\phi_1} \) of CM forms in

\[
\text{Spec } T^\perp \quad \text{for some ray class character } \phi_1 \neq \phi \text{ or } \phi^c \text{ whose specialization at some arithmetic point } P' \text{ above } P \text{ agree with } \theta_{\phi}^{(\Sigma^p)},
\]

which in turns suggests that \( \phi_1 + \phi_1^c = \phi + \phi^c \), and \( \phi_1 = \phi \) or \( \phi^c \), a contradiction.

By [HT94, Theorem 6.12], for each \( \mathfrak{p} \mid \mathfrak{p} \), the subspace \( L_{\mathcal{H}_i} \mathfrak{p} \) fixed by the inertia group \( \rho_{\mathcal{H}_i} \mathfrak{p} \) is one-dimensional over \( L_{\mathcal{H}_i} \). Let \( v_{\mathcal{H}_i,\mathfrak{p}} \) be a basis. Since \( \mathcal{H}_i \) are not Hida families of CM forms, the Galois representations \( \rho_{\mathcal{H}_i}|_{G_{K,S}} \) are irreducible. Combining the \( \Sigma\text{-Leopoldt's conjecture } \Sigma\text{-Leop} \) and \( \phi \neq \phi^c \), we can apply the
argument [DKV18 Lemma 4.3] shows that there exists \( \sigma_0 \in G_{K,S} \) such that \( \phi(\sigma_0) \neq \phi(\sigma_0 c) \) and \( v_{H,p} \) is not an eigenvector for all \( H \) and \( p \). Choosing a basis \( \{ v_1, v_2 \} \) consisting of eigenvectors of \( \rho_{\lambda}(\sigma_0) \) for the representation \( \rho_{\lambda} \), we may assume

\[
(6.3) \quad \rho_{\lambda}(\sigma_0) = \begin{pmatrix} \nu_1 & 0 \\ 0 & \nu_2 \end{pmatrix}, \quad \nu_1 \equiv \phi(\sigma_0) \pmod{m_R}; \quad \nu_2 \equiv \phi(\sigma_0 \sigma_0 c) \pmod{m_R}.
\]

The image \( \rho_{\lambda}(R[G_{K,S}]) \) of the group ring \( R[G_{K,S}] \) is of the form

\[
\rho_{\lambda}(R[G_{K,S}]) = \begin{pmatrix} R & R_{12} \\ R_{21} & R \end{pmatrix} \subset M_2(R),
\]

where \( R_{ij} \) are ideals in \( R \); this is a generalized matrix algebra in the sense of [BC09 Theorem 1.4.4]. Note that \( R_{12} \) is a faithful \( R \)-module since \( \rho_{\lambda}|_{G_{K,S}} \) is irreducible for all \( i \). Writing

\[
\rho_{\lambda}(\sigma) = \begin{pmatrix} a(\sigma) & b(\sigma) \\ c(\sigma) & d(\sigma) \end{pmatrix} \quad \text{for } \sigma \in G_{K,S},
\]

it follows from (6.2) and (6.3) that

\[
a(\sigma) \equiv \phi(\Psi(\sigma)) \pmod{I}, \quad d(\sigma) \equiv \phi(\sigma c) \pmod{I}; \quad R_{12}R_{21} \subset IR.
\]

For each \( p \mid \mathfrak{p} \), the \( \rho_{\lambda}(I_{G_{K,S}}) \)-fixed vector \( v_p := (v_{H,p})_{H=1,\ldots,i} \) is an eigenvector of \( \rho_{\lambda}(G_{K_{\mathfrak{p}}}) \) such that \( \rho_{\lambda}(\sigma)v_p = \alpha_p(\sigma)v_p \), where \( \alpha_p : G_{K_{\mathfrak{p}}} \to T^+ \) is the unramified character with \( \alpha_p(U_{\mathfrak{p}}) = U_p \). Writing \( v_p = A_pv_1 + C_pv_2 \) with \( (C_p, D_p) \in (\text{Frac} R)^2 \), we obtain an invertible matrix \( \begin{pmatrix} A_p & B_p \\ C_p & D_p \end{pmatrix} \in \text{GL}_2(\text{Frac} R) \) such that

\[
\begin{pmatrix} a(\sigma) & b(\sigma) \\ c(\sigma) & d(\sigma) \end{pmatrix} \begin{pmatrix} A_p & B_p \\ C_p & D_p \end{pmatrix} = \begin{pmatrix} A_p & B_p \\ C_p & D_p \end{pmatrix} \begin{pmatrix} \alpha_p(\sigma) & * \\ 0 & * \end{pmatrix} \quad \text{for all } \sigma \in G_{K_{\mathfrak{p}}}.
\]

It follows that

\[
(6.4) \quad C_p \cdot b(\sigma) = A_p \cdot (\alpha_p(\sigma) - a(\sigma)) \quad \text{for } \sigma \in G_{K_{\mathfrak{p}}}.
\]

Note that \( A_p \) and \( C_p \) both belong to \( (\text{Frac} R)^\times \) since \( v_{H,p} \) is not an eigenvector of \( \rho_{\lambda}(\sigma_0) \) for each \( i \). Define the function

\[
\kappa : G_{K,S} \to R_{12}, \quad \kappa(\sigma) = b(\sigma)/d(\sigma).
\]

For any \( R \)-submodule \( R' \supseteq \mathfrak{m}_R R_{12} \) of \( R_{12} \), the reduction of \( \kappa \) modulo \( R' \)

\[
\kappa := b/d \pmod{R'}, \quad \kappa(\sigma) = b(\sigma)/d(\sigma)
\]

is a continuous one-cocycle in \( Z^1(G_{K,S}, \chi \otimes R_{12}/R') \). We claim that if the class \( \kappa \) is zero, then \( R_{12} = R' \). We can write \( b(\sigma) \pmod{R'} = (\phi^c(\sigma) - \phi(\sigma))z \) for some \( z \in R_{12}/R' \). Evaluating \( b(\sigma) \) at \( \sigma = \sigma_0 \), we immediately see that \( z = 0 \) from (6.3) and hence \( b(\sigma) \pmod{R'} = 0 \). Since \( R_{12} \) is the \( R \)-module generated by \( \{ b(\sigma) \}_{\sigma \in G_{K,S}} \), we conclude \( R_{12} = R' \). In particular, this shows that \( \kappa \) is a non-zero class.

Let \( p \) be a prime of \( \mathfrak{o} \) above \( p \) and write \( \mathfrak{p} \mathfrak{o} = \mathfrak{P} \mathfrak{p} \mathfrak{P} \) with \( \mathfrak{P} \in \Sigma_p \). Suppose that \( \mathfrak{P} \notin \Sigma_p^{\text{irr}} = \{ \mathfrak{P}_1, \ldots, \mathfrak{P}_r \} \), i.e. \( \phi \neq \phi^c \) on \( G_{K_{\mathfrak{p}}} \). Then there exists \( \sigma_p \) with \( \alpha_p(\sigma_p) - a(\sigma_p) \in R^\times \). We thus obtain

\[
\kappa(\sigma) = \frac{A_p}{C_p} \cdot \frac{(\alpha_p(\sigma) - a(\sigma))}{d(\sigma)},
\]
and $\overline{\mathcal{F}}(\sigma) = \frac{A}{C_p}(1-\chi(\sigma)) \pmod{m_R R_{12}}$ for all $\sigma \in G_{K_{\overline{\mathbb{P}}}}$. This shows that the class $[\overline{\mathcal{F}}]$ is locally trivial at $\overline{\mathbb{P}}$ for any $\mathbb{P} \in \Sigma_p \setminus \Sigma_p^{irr}$. Let $R'_{12}$ be the submodule of $R_{12}$ generated by $\{\mathcal{F}(\sigma)\}_{\sigma \in G_{K_{\overline{\mathbb{P}}}}}$ with $\mathbb{P}_i \in \Sigma_p^{irr}$. Then $\overline{\mathcal{F}} : G_K \to \frac{R_{12}}{(m_R R_{12} + R'_{12})}$ is a cocycle whose class $[\overline{\mathcal{F}}]$ is locally trivial outside $\Sigma_p$, and we see that $[\overline{\mathcal{F}}] = 0$ by the $\Sigma$-Leopoldt conjecture ($\Sigma$-Leo). From the above claim, we obtain that $m_R R_{12} + R'_{12} = R_{12}$ and hence $R'_{12} = R_{12}$ by Nakayama’s lemma. Let $\tilde{\varepsilon}_i = \phi \Psi(F_{r_{\overline{\mathbb{P}}}}^{-1}) U_p - 1 \in R$ and $Z \in R$ be liftings of $\varepsilon_i$ and $Z$ respectively. Then the assumption (i) implies that $\alpha_{p_i}(\sigma) - a(\sigma) \in \tilde{\varepsilon}_i R + \tilde{Z} R + \mathbf{I}$ for $\sigma \in G_{K_{\overline{\mathbb{P}}}}$. Therefore, we conclude that

$$
R_{12} \subset \sum_{i=1}^r \frac{A_{p_i}}{C_{p_i}} (\tilde{\varepsilon}_i R + \tilde{Z} R + \mathbf{I}).
$$

For each integral prime $\Omega$ of $K$, denote by

$$
\langle \cdot, \cdot \rangle : H^1(K_{\Omega}, \chi \otimes R_{12}/m_R) \times H^1(K_{\Omega}, \chi^{-1}(1)) \rightarrow R_{12}/m_R
$$

the local Tate pairing. We choose a basis $\{u_1, u_2, \ldots, u_r\}$ of $H^1_{(0,0)}(K, \chi^{-1}(1))$. Since the class $\kappa_\lambda$ is unramified outside $\Sigma_p \cup \Sigma_p^{irr}$, we obtain

$$
\sum_{i=1}^r (\text{loc}_{\overline{\mathbb{P}}_i}(\kappa_\lambda), \text{loc}_{\overline{\mathbb{P}}_i}(u_j))_{\overline{\mathbb{P}}_i} = 0 \text{ in } R_{12}/m_R.
$$

For $\sigma \in G_{K_{\overline{\mathbb{P}}}}$, we have

$$
\phi^* \Psi^*(\sigma^{-1})(\alpha_{p_i}(\sigma) - a(\sigma)) = \Psi(\sigma)(1 + \varepsilon_i)\alpha_{\sigma}(\psi - \Psi(\sigma) + \psi(\sigma)Z)
$$

$$
\equiv \alpha_{\sigma}(\varepsilon_i - \psi(\sigma)Z) \pmod{I + \tilde{Z} m_R}.
$$

Put $a_{ij} = (\text{ord}_{\overline{\mathbb{P}}_i}, \text{loc}_{\overline{\mathbb{P}}_i}(u_j))_{\overline{\mathbb{P}}_i}$ and $\psi_{ij} = (\text{loc}_{\overline{\mathbb{P}}_i}(\psi), \text{loc}_{\overline{\mathbb{P}}_i}(u_j))_{\overline{\mathbb{P}}_i}$. According to Definition 2.2

$$
\mathcal{L}_\psi := (-1)^r \frac{\det((\psi_{ij}))}{\det((a_{ij}))}.
$$

It follows from (6.7) that

$$
\sum_{i=1}^r \frac{A_{p_i}}{C_{p_i}} (a_{ij} \tilde{\varepsilon}_i - \psi_{ij} \tilde{Z} + m_{ij}) \equiv 0 \pmod{m_R R_{12}} \text{ for some } m_{ij} \in I + \tilde{Z} m_R.
$$

Combining (6.6), we obtain

$$
\sum_{i=1}^r \frac{A_{p_i}}{C_{p_i}} (a_{ij} \tilde{\varepsilon}_i - \psi_{ij} \tilde{Z} + m_{ij}) = 0 \text{ for some } m_{ij} \in I + \tilde{Z} m_R + \tilde{\varepsilon}_i m_R.
$$

Hence, we have

$$
\det(a_{ij} \tilde{\varepsilon}_i - \psi_{ij} \tilde{Z} + m_{ij}) = 0.
$$

Applying $\lambda$ on both sides, we obtain

$$
\det(a_{ij} \varepsilon_i - \psi_{ij} Z + \lambda(m_{ij})) = 0, \quad \lambda(m_{ij}) \in (Z, \varepsilon_i) m_W.
$$

Since $\varepsilon_i Z = \varepsilon_i m_W = 0$, we find that that

$$
\det(a_{ij} \varepsilon_i - \psi_{ij} Z + \lambda(m_{ij})) \equiv \det(a_{ij})\varepsilon_1 \cdots \varepsilon_r + (-1)^r \det(\psi_{ij})Z^r \pmod{Z^r m_W}
$$

$$
\equiv \det(a_{ij}) \cdot (-bY^r + \mathcal{L}_\psi Z^r) \pmod{Z^r m_W}.
$$
The proposition follows immediately.

6.2. Applications to the Katz $p$-adic $L$-functions. Let $\chi$ be a non-trivial anticyclotomic character of conductor $\mathfrak{f}_K$ as in §5.4. Recall that in the $\Lambda$-adic cusp form $\mathcal{H}$ in Definition 5.2 is given by

$$\mathcal{H} = c_{\text{ord}}(G(m, l_0) \cdot \theta_0) - \frac{1}{B} \theta_{\phi^c} - \frac{1}{A} \theta_{\phi} \in S^0_K.$$  

with $A = C(\phi, \phi^c)^{-1}$ and $B = C(\phi^c, \phi)^{-1}$ in $K^\times = (\text{Frac} \Lambda)^\times$. We shall assume that the Leopoldt conjecture for $F$ holds, which is, by a result of Colmez [Col88], equivalent to the following

$$(F\text{-Leo}) \quad \zeta_{F, p}(s) \text{ has a simple pole at } s = 1 \iff \frac{1}{\zeta_{F, p}(s)} \in X \Lambda_P.$$ 

By the constant term formula (5.7) and the definition of the $\Lambda$-adic Eisenstein series $G(m, l_0)$ in (5.9), we find that (F-Leo) implies that

$$(6.8) \quad G(m, l_0) \equiv 1 \pmod{X}.$$ 

We continue to assume that $r = r_\Sigma(\chi) > 0$ in this subsection. For $i = 1, \ldots, r$, we put

$$\bar{\varepsilon}_i := \phi(\Psi^{-1}) U_p, -1 \in T.$$ 

**Proposition 6.2.** Assume that (F-Leo) and ($\Sigma$-Leo) hold. Then we have

$$B \in X \Lambda_P.$$ 

**Proof.** Suppose that $B \not\in X \Lambda_P$. Namely, $B^{-1} \in \Lambda_P$. There are two cases:

Case (i): $A^{-1} \in \Lambda_P$. Let $\tilde{A}$ act on $S^1$ by

$$(6.9) \quad \varepsilon_1 \cdot \mathcal{F} = \bar{\varepsilon}_1 \mathcal{F}; \quad Y \cdot \mathcal{F} = \varepsilon_1 \ldots \varepsilon_r \cdot \mathcal{F}.$$ 

Define the ideal $I$ of $\tilde{\Lambda}$ by

$$I := I_{1, 1, 0, -1} = (X, \varepsilon_1^2, \ldots, \varepsilon_r - Y)$$

and $W := \tilde{\Lambda}/I$. Then one verifies immediately that $\mathcal{F}_0 := \mathcal{H} \pmod{X}$ is annihilated and $W \cdot \mathcal{F}_0$ is a free of $W$-module of rank one. We have a homomorphism $\lambda : T^1 \to W$ with

$$\lambda(T_i) = \phi(\mathfrak{f}) + \phi(\mathfrak{f})$$

if $l = \mathfrak{f} \mathfrak{f}$ is split in $K$,

$$\lambda(T_i) = 0$$

if $l$ is inert in $K$,

$$\lambda(U_p) = \phi(\mathfrak{f})$$

if $p = \mathfrak{f} \mathfrak{f}$ with $\mathfrak{f} \in \Sigma_p \setminus \Sigma_{\text{irr}}$,

$$\lambda(U_{p_i}) = \phi(\mathfrak{f}) (1 + \varepsilon_i)$$

if $p_i = \mathfrak{f} \mathfrak{f}$ with $\mathfrak{f}_i \in \Sigma_{\text{irr}}$. 

Applying Proposition 6.1 to $\lambda$ with $\tilde{\Psi} = 1$, $Z = X$ and $\psi = 0$, we find that

$$Y \in X^r m_W = \{0\}.$$ 

This is a contradiction.

Case (ii): $A \in \mathcal{P} \Lambda_P$. Let $r_A = \text{ord}_p(A) \geq 1$ and $a^* = A/X^r A|_{X = 0} \in \overline{\mathbb{Q}}_p^\times$. We let $\tilde{A}$ act on $S^1/(X^r A^1)$ by

$$Y \cdot \mathcal{F} = X \mathcal{F}, \quad \varepsilon_i \cdot \mathcal{F} = \bar{\varepsilon}_i \mathcal{F}.$$
we verify easily that

\[ \mathcal{L}_\chi^{\text{ac}} = \mathcal{L}_\chi^{\text{ac}} \]
\[ \text{along the} \ \text{anticyclotomic logarithm} \ \ell^{\text{ac}} \in \text{Hom}(G_K, \mathcal{K}) \text{ given by} \]
\[ \ell^{\text{ac}} = \log_p \circ \varepsilon_{\Sigma}^{1-c} = \eta_{\Sigma} - \eta_\Sigma. \]
\[ \text{We next apply Proposition 6.1 to relate the anticyclotomic} \ L \text{-invariant} \]
\[ \mathcal{L}_\chi^{\text{ac}} \text{ to the higher order derivatives of} \ B. \]

**Proposition 6.3.** **With the Leopoldt hypotheses (F-Leo) and (\Sigma-Leo), we have**
\[ \mathcal{L}_\chi^{\text{ac}} = \frac{B}{X^r} \bigg|_{X=0}. \]

**Proof.** Write \( \mathcal{G} = \mathcal{G}(m, l_0) \) and consider
\[ \mathcal{H} = c_{\ord}(\mathcal{G}^\theta_\phi) - 1 / B \theta_{\phi^e} - 1 / A \theta_\phi \in S_K. \]
\[ \text{By Proposition 6.2} \]
\[ B = C(\phi^e, \phi)^{-1} \in X A. \] \[ \text{We set} \ r_A = \ord_p(A) \text{ and} \ r_B = \ord_p(B) \geq 1. \] \[ \text{Put} \]
\[ b^* := \frac{B}{X^{r_B}} \bigg|_{X=0} \in \mathcal{Q}_p. \]
In what follows, \( I \) denotes an integral prime of \( F \) with \((I, \mathfrak{p}m) = 1 \) and \( \Sigma \) is a prime of \( K \) above \( I \). Let \( \tau_{K/F} \) be the quadratic ideal character of \( F \) associated with \( K/F \). Choose a prime-to-\( p \) prime ideal \( \mathfrak{q}_0 = \Omega_0 \mathfrak{G}_0 \) split in \( K \) such that

\[
\phi(\Omega_0) - \phi(\mathfrak{G}_0) \neq 0 \quad \text{and} \quad \ell^{\text{ord}}(\mathfrak{F}_\mathfrak{G}_0) \neq 0.
\]

This implies that \( C(q_0, \theta_\phi) - C(q_0, \theta_\phi^e) \in X \Lambda_p^\alpha \). Define the Hecke operators \( Y_\phi \) and \( Y_{\phi^e} \) in \( T_p \) by

\[
Y_\phi := \frac{(T_{q_0} - C(q_0, \theta_\phi))X}{C(q_0, \theta_\phi^e) - C(q_0, \theta_\phi)}\quad \text{and} \quad Y_{\phi^e} := \frac{(T_{q_0} - C(q_0, \theta_\phi^e))X}{C(q_0, \theta_\phi) - C(q_0, \theta_\phi^e)}.
\]

**Case (I):** \( \Sigma_p^\text{irr} \neq \Sigma_p \). Let \( \tilde{\Lambda} \) act on \( S^\perp/(X^{r_B+1}) \) by

\[
Y \cdot \mathcal{F} = Y_\phi \mathcal{F}; \quad \epsilon_i \cdot \mathcal{F} = \tilde{\epsilon}_i \mathcal{F}.
\]

Let \( \mathfrak{p}_0 \in \Sigma_p - \Sigma_p^\text{irr} \) and \( p_0 \mathfrak{o}_K = \mathfrak{p}_0 \mathfrak{G}_0 \). Put

\[
\mathcal{H}_1 := \frac{-B}{\phi(\mathfrak{p}_0) - \phi(\mathfrak{G}_0)}(U_{p_0} - \phi(\mathfrak{G}_0))\mathcal{H} = \theta_\phi^e - B \cdot e_{\text{ord}}(G_{\theta_\phi^e}) \in S^\perp;
\]

\[
\mathcal{F}_1 := \mathcal{H}_1 (\mod X^{r_B+1}).
\]

By [6:8], we have

\[
\mathcal{F}_1 = \theta_\phi^e - b^* \theta_\phi^e X^{r_B} (\mod X^{r_B+1}).
\]

One verifies that

\[
Y \cdot \mathcal{F}_1 = X \mathcal{F}_1 = X \theta_\phi^e (\mod X^{r_B+1}),
\]

\[
\epsilon_1 \ldots \epsilon_r \cdot \mathcal{F}_1 = -b^* X^{r_B} \mathcal{F}_1,
\]

\[
\tilde{\epsilon}_1^* \cdot \mathcal{F}_1 = B \phi(\mathfrak{p}_1^{-2})(U_{p_1} - \phi(\mathfrak{G}_1))\theta_\phi^e (\mod X^{r_B+1}) = 0.
\]

Thus \( \mathcal{F}_1 \) is annihilated by the ideal

\[
I := I_{r_B, 1, 1, b^*} = (X^{r_B+1}, Y - X, \epsilon_1^2, X \epsilon_1, \epsilon_1 \epsilon_2 \ldots \epsilon_r + b^* X^{r_B}) \subset \tilde{\Lambda}.
\]

Let \( W = \tilde{\Lambda}/I \). For each subset \( J \) of \( \{1, 2, \ldots, r\} \), put \( \epsilon_J := \prod_{i \in J} \epsilon_i \). It is easy to see that \( W \) is generated by the \( \Lambda_p \)-algebra \( W \) generated by \( \{X_i\}_{i=0}^{r_B-1} \) and the products \( \epsilon_J \) with \( J \neq \emptyset \) over \( \overline{\mathbb{Q}}_p \). We claim that \( W \cdot \mathcal{F}_1 \) is a free \( W \)-module of rank one. To see it, it suffices to show that \( \{X_1^i \mathcal{F}_1\}_{i=0}^{r_B-1} \) and \( \{\epsilon_J \mathcal{F}_1\}_{J \neq \emptyset} \) are linearly independent. Suppose that there exists a polynomial \( f(X) \) with \( \deg f < r_B \) and \( \alpha_J \in \overline{\mathbb{Q}}_p \) with \( J \subset \{1, \ldots, r\} \) such that

\[
f(X) \mathcal{F}_1 + \sum_{J \subset \{1, \ldots, r\}, J \neq \emptyset} \alpha_J \epsilon_J \mathcal{F}_1 = 0.
\]

We must show that \( f(X) = 0 \) and \( \alpha_J = 0 \). Applying \( Y \) on both sides, we get

\[
X f(X) \theta_\phi^e \equiv 0 (\mod X^{r_B+1}).
\]
Noting that \( C(\alpha, \theta_{\phi}) = 1 \), we obtain \( Xf(X) \equiv 0 \) (mod \( X^{r_B+1} \)). This implies that 
\[
0 = \sum_{J \subseteq \{1, \ldots, r\}, J \neq \emptyset} \alpha_J \varepsilon_J \cdot \mathcal{F}_J = X^{r_B} \left( \sum_{J \neq \emptyset} \alpha_J \varepsilon_J \cdot \theta_{\phi}^J \right) \pmod{X^{r_B+1}}.
\]

Now the claim follows from the linear independence of the set \( \{ \varepsilon_J \cdot \theta_{\phi}^J \}_{J} \) of modular forms. From (5.3), we deduce that 
\[
T_i \mathcal{F}_1 = (\phi(T) \Psi(Fr_{\overline{F}}) + \tau_{K/F}(1) \phi(T) \Psi(Fr_{\overline{F}})) \mathcal{F}_1;
\]
\[
U_p \mathcal{F}_1 = \phi(p) \Psi(Fr_{\overline{F}}) \mathcal{F}_1, \quad p = \mathfrak{p} \mathfrak{p}^* \text{ with } \mathfrak{p} \in \Sigma_p \setminus \Sigma_{irr};
\]
\[
U_p \mathcal{F}_1 = \phi(\Psi(Fr_{\overline{F}}))(1 + \varepsilon_i) \cdot \mathcal{F}_1 \text{ for } i = 1, \ldots, r.
\]

This shows that the free \( W \)-module \( W \cdot \mathcal{F}_1 \) is a \( \mathbf{T}^1 \)-invariant submodule of \( S^1/(X^{r_B+1}) \). This induces a surjective \( \Lambda_p \)-alegbra homomorphism \( \lambda : \mathbf{T}^1 \to W \) such that 
\[
t \mathcal{F}_1 = \lambda(t) \cdot \mathcal{F}_1.
\]
This \( \lambda \) satisfies the assumptions in Proposition 6.1 with \( \Psi = \Psi^r \), \( Z = X \) and \( \psi = \ell^{ac} \). Applying Proposition 6.1 we obtain
\[
-b^* X^{r_B} + L_{\chi}^{ac} \cdot X^r \equiv 0 \pmod{X^r m_W}.
\]
This implies that \( r_B \geq r \) and that \( L_{\chi}^{ac} = 0 \) if \( r_B > r \) and \( L_{\chi}^{ac} = b^* \) if \( r_B = r \).

**Case (II):** \( \Sigma_p = \Sigma_{irr}^p \) and \( r_B \geq r_A \). Define the \( \Lambda_p \)-adic cuspform 
\[
\mathcal{H}_2 := (-B) \cdot \mathcal{H} = \frac{B}{A} \cdot \theta_{\phi} + \theta_{\phi^e} - B \cdot e_{\text{ord}}(\mathcal{G} \theta_{\phi}^e).
\]
Let \( \mathcal{F}_2 := \mathcal{H}_2 \pmod{X^{r_B+1}} \). Let \( Y \) and \( \varepsilon_i \) act on \( \mathcal{H}_2 \) as in (6.13) and set \( z_2 = 1 + \frac{B}{A} \in \Lambda_p \). Then one verifies that 
\[
Y \cdot \mathcal{F}_2 = X \theta_{\phi^e}, \quad Y \cdot \theta_{\phi^e} = X \theta_{\phi^e},
\]
\[
X^{r_A} \mathcal{F}_2 = z_2 Y^{r_A} \cdot \mathcal{F}_2,
\]
\[
\varepsilon_1 \cdots \varepsilon_r \cdot \mathcal{F}_2 = -b^* X^{r_B} \theta_{\phi}^{(\Sigma_p)} = -b^* Y^{r_B} \cdot \mathcal{F}_2.
\]
This shows that \( \mathcal{F}_2 \) is annihilated by the ideal 
\[
I := I_{r_B, r_A, z_2, b^*} = (Y^{r_B+1}, \varepsilon_1^2 \cdot X \varepsilon_i, Y \varepsilon_i, Y(X-Y), X^{r_A} - z_2 Y^{r_A}, \varepsilon_1 \varepsilon_r + b^* Y^{r_B}).
\]
Let \( W = \overline{\Lambda}/I \). We claim that \( W \cdot \mathcal{F}_2 \) is a free \( W \)-module. To see it, since \( W/I \) is generated by \( \{X^i\}_{i=0}^{r_A-1} \cup \{Y^j\}_{j=1}^{r_B-1} \cup \{\varepsilon_j\}_{J \neq \emptyset} \); it suffices to show that 
\[
\{X^i \mathcal{F}_2\}_{i=0}^{r_A-1} \cup \{Y^j \mathcal{F}_2\}_{j=1}^{r_B-1} \cup \{\varepsilon_j \mathcal{F}_2\}_{J \subseteq \Sigma_p, J \neq \emptyset} \subseteq \mathcal{F}_2
\]
are linearly independent over \( \overline{Q}_p \). Suppose that we have a linear equation 
\[
f(X) \mathcal{H}_2 + g(Y) Y \cdot \mathcal{H}_2 + \sum_{J \neq \emptyset} \alpha_J \varepsilon_J \cdot \mathcal{H}_2 \equiv 0 \pmod{X^{r_B+1}}
\]
for some polynomials \( f(X), g(X) \in \overline{Q}_p[X] \) with \( \deg f < r_A \) and \( \deg g < r_B - 1 \). Applying \( Y \) on both sides, we obtain 
\[
(f(X) + g(X)X) X \theta_{\phi^e} \equiv 0 \pmod{X^{r_B+1}},
\]
and hence \( f(X) + g(X)X \equiv 0 \pmod{X^{r_B}} \) as \( C(a, \theta_{\phi^e}) = 1 \). It follows that
\[
\begin{align*}
    f(X) + g(X)X &= 0; \\
    f(X)X^{r_B - r_A} u \theta_{\phi} + \sum_{j \neq \emptyset} \alpha_j b^* X^{r_B} \varepsilon_j \theta_{\phi}^p &= 0, \quad u = \frac{B}{A X^{r_B - r_A}} \in \Lambda_{\mathbb{P}}.
\end{align*}
\]

We find that \( f(X)X^{r_B - r_A} = 0 \pmod{X^{r_B}} \), which in turn shows that \( f(X) = 0 \) for \( \deg f < r_A \). In view of (6.14), we thus get \( g(X) = 0 \) and \( \alpha_J = 0 \) for \( J \neq \emptyset \). On the other hand, a direct calculation shows that
\[
    T_i \mathcal{F}_2 = (\phi \Psi_2(\text{Fr}_F) + \tau_{K/F}(l) \phi \Psi_2(\text{Fr}_F)) \mathcal{F}_2,
\]
where \( \Psi_2 : G_{K,S} \to W^X \) is the character defined by
\[
    \Psi_2(\sigma) = \Psi(\sigma) + \frac{\Psi^e(\sigma) - \Psi(\sigma)}{X} Y.
\]

This shows that \( W \cdot \mathcal{F}_2 \) is an invariant \( T^1 \)-submodule. We therefore obtain the surjective homomorphism \( \lambda : T^1 \to W \) such that \( t \mathcal{F}_2 = \lambda(t) \cdot \mathcal{F}_2 \). Applying Proposition 6.1 to \( \lambda \) with \( \tilde{\Psi} = \Psi_2, Z = Y \) and \( \psi = e^w \), we find that
\[
    -b^* Y^{r_B} + \mathcal{L}_{X}^{\text{ac}} Y^r \equiv 0 \pmod{Y^r m_W}.
\]

This implies that \( r_B \geq r \) and that \( \mathcal{L}_{X}^{\text{ac}} = 0 \) if \( r_B > r \) and \( \mathcal{L}_{X}^{\text{ac}} = b^* \) if \( r_B = r \).

**Case (III):** \( \Sigma_p = \Sigma_p^{\text{ur}} \) and \( r_A > r_B > 0 \). Let \( a^* = \frac{A}{X^{r_A}} | \chi = 0 \in \overline{Q}_p^X \). Put
\[
    \mathcal{H}_3 := (-A) \mathcal{H} = \theta_{\phi} + \frac{A}{B} \cdot \theta_{\phi^e} - A \cdot \varepsilon_{\text{ord}}(\theta_{\phi}).
\]

Let \( W \) act \( S^1/(X^{r_A} + 1) \) by
\[
    Y \cdot \mathcal{F} := \frac{(T_{q_0} - C(q_0, \theta_{\phi^e}))X}{C(q_0, \theta_{\phi}) - C(q_0, \theta_{\phi^e})} \mathcal{F}; \quad \varepsilon_i \cdot \mathcal{F} = (\phi \Psi(\text{Fr}_F^{-1}) U_p - 1) \mathcal{F}.
\]

Put \( \mathcal{F}_3 = \mathcal{H}_3 \pmod{X^{r_A} + 1} \). One verifies easily that
\[
    Y \cdot \mathcal{F}_3 = Y \cdot \theta_{\phi} \equiv X \theta_{\phi} \pmod{X^{r_A} + 1}; \quad \varepsilon_1 \ldots \varepsilon_r \cdot \mathcal{F}_3 \equiv -A \cdot \theta_{\phi} \equiv -a^* \cdot X^{r_A} \theta_{\phi} \pmod{X^{r_A} + 1}.
\]

One verifies that
\[
    X^{r_B} \mathcal{F}_3 = (1 + \frac{A}{B}) Y^{r_B} \cdot \mathcal{F}_3, \quad \varepsilon_1 \ldots \varepsilon_r \cdot \mathcal{F}_3 = -a^* Y^{r_A} \cdot \mathcal{F}_3.
\]

Setting \( z_3 = 1 + \frac{A}{B} \in \Lambda_{\mathbb{P}} \), it follows that \( \mathcal{H}_3 \) is annihilated by the ideal
\[
    I_3 := I_{r_A, r_B, z_3, a^*},
\]
\[
    = (Y^{r_A} + 1, \varepsilon_1^2, X \varepsilon_1, Y \varepsilon_1, Y(X - Y), X^{r_B} - z_3 Y^{r_B}, \varepsilon_1 \ldots \varepsilon_r + a^* Y^{r_A}).
\]

By a similar argument as in the case (II), one can show that \( \{ X^i \mathcal{F}_3 \}_{i=0}^{r_B - 1}, \{ Y^j \cdot \mathcal{F}_3 \}_{j=1}^{r_A - 1} \) and \( \{ \varepsilon_j \cdot \mathcal{F}_3 \}_{j \neq \emptyset} \) are linearly independent and conclude that \( W \cdot \mathcal{F}_3 \) is free of rank one over \( W \). By (5.3), we also verify that
\[
    T_i \mathcal{F}_3 = (\phi \Psi_3(\text{Fr}_F) + \tau_{K/F}(l) \phi \Psi_3(\text{Fr}_F)) \cdot \mathcal{H}_3,
\]
where \( \Psi_3 : G_{K,S} \to W^\times \) is defined by

\[
\Psi_3(\sigma) = \Psi(\sigma) + \Psi(\sigma) - \Psi(\sigma) Y.
\]

Applying Proposition 6.1 to \( \lambda \) with \( \Psi = \Psi_3 \), \( Z = X - Y \) and \( \psi = \ell_{ac} \), we obtain

\[
-a^r Y^\sigma + \mathcal{L}_{\chi}^{ac}(X - Y)^r \equiv 0 \pmod{\lambda}.
\]

Since \( r_A > r_B \), we have \( Z^{r_B} = (X - Y)^{r_B} = \frac{a^r}{c^r} Y^r A \in W \). This implies that \( r_B \geq r \) and that \( \mathcal{L}_{\chi}^{ac} = 0 \) if \( r_B > r \) and \( \mathcal{L}_{\chi}^{ac} = b^r \) if \( r_B = r \). This finishes the proof in all cases.

\[\text{Theorem 6.4. Suppose that } (F, \text{Leo}) \text{ and } (\Sigma, \text{Leo}) \text{ hold. Then we have}
\]

\[
\text{ord}_{s=0} \mathcal{L}_{\Sigma}(s, -s, \chi) \geq r
\]

and

\[
\lim_{s \to 0} \mathcal{L}_{\Sigma}^*(s, -s, \chi) = \mathcal{L}_{\chi}^{ac} \cdot \mathcal{L}_{\Sigma}^*(0, \chi) \prod_{\mathfrak{p} \in \Sigma_p \setminus \Sigma_p^{irr}} (1 - \chi(\mathfrak{p})).
\]

\[\text{Proof. Let } B(s) := \varepsilon_{K_p}^*(B) \text{ be the meromorphic function on } \mathcal{Z}_p. \text{ Then } B(s)/s^r|_{s=0} = B/X^r|_{X=0} \text{ based on the choice of the uniformizer } X. \text{ By Proposition 5.3}
\]

\[
B(s) = \frac{1}{(Nm)^s} \cdot \mathcal{L}_{\Sigma}(s, -s, \chi) \prod_{\mathfrak{p} \in \Sigma_p \setminus \Sigma_p^{irr}} (1 - \chi(\mathfrak{p})) \cdot h_{K/F}
\]

\[
\times \zeta_{K_p}(1 - s) \prod_{\mathfrak{p} \in \Sigma_p} (1 - \varepsilon_{K_p}^*(F(\mathfrak{p}))) \cdot \mathcal{L}_{\Sigma}(s, 0, 1) \langle \Delta_K \mathfrak{N} \mathfrak{e}_k \rangle^s \cdot \text{Ex}_{10}(s).
\]

To simply the notation, we put

\[
\mathcal{L}_{\Sigma}^*(s, \chi) := \mathcal{L}_{\Sigma}(s, \chi) \prod_{\mathfrak{p} \in \Sigma_p \setminus \Sigma_p^{irr}} (1 - \chi(\mathfrak{p})).
\]

Combined with Proposition 6.3, Proposition 4.8 and Ex_{10}(0) = 1, we obtain

\[
\mathcal{L}_{\chi}^{ac} = \frac{B(s)}{s^r}|_{s=0} = \frac{\mathcal{L}_{\Sigma}(s, -s, \chi)}{s^r \mathcal{L}_{\Sigma}^*(s, \chi)}|_{s=0}.
\]

The theorem follows.

\[\text{Corollary 6.5. Suppose that the Leopoldt hypotheses } (F, \text{Leo}) \text{ and } (\Sigma, \text{Leo}) \text{ hold and that } (\ell, p)_{K/F} = 1. \text{ Suppose that } r_{\Sigma}(\chi) > 0 \text{ and } \mathfrak{P}_1 \in \Sigma_p^{irr}. \text{ Then we have}
\]

\[
\mathcal{L}_{\Sigma}(0, \chi) = 0 \text{ and }
\]

\[
\mathcal{L}_{\Sigma}^*(s, \chi)|_{s=0} = \mathcal{L}_{\chi} \cdot \mathcal{L}_{\Sigma}^*(0, \chi) \prod_{\mathfrak{p} \in \Sigma_p \setminus \{\mathfrak{P}_1\}} (1 - \chi(\mathfrak{p})).
\]

\[\text{Proof. Let } r = r_{\Sigma}(\chi). \text{ Since } \eta_{\Sigma}(\mathfrak{F}_\mathfrak{P}) = -\log_p(\varepsilon_{\Sigma}(\mathfrak{F}_\mathfrak{P})) \text{ for } \mathfrak{P} \in \Sigma_p. \text{ By Theorem 4.9 we see that ord}_{s=0}(\mathcal{L}_{\Sigma}(s, 0, \chi)) = r \text{ and if } r = 1 \text{ and } \Sigma_p^{irr} = \{\mathfrak{P}_1\}, \text{ then}
\]

\[
\mathcal{L}_{\Sigma}(s, 0, \chi)|_{s=0} = \eta_{\Sigma}(\mathfrak{F}_{\mathfrak{P}_1}) \cdot \mathcal{L}_{\Sigma}^*(0, \chi).
\]

This implies that \( \mathcal{L}_{\Sigma}(s, \chi)|_{s=0} = 0 \) if \( r > 1 \) in view of Theorem 6.4. Now suppose that \( r = 1 \). Note that the cyclotomic logarithm \( \ell_{ac} = -\eta_{\Sigma} - \eta_{\Sigma}^* \), so if \( r = 1 \) and \( \Sigma_p^{irr} = \{\mathfrak{P}_1\} \), then

\[
\mathcal{L}_{\chi}^{ac} = 2\eta_{\Sigma}(\mathfrak{F}_{\mathfrak{P}_1}) - \mathcal{L}_{\chi}.
\]
It follows that the cyclotomic derivative \( \frac{\mathcal{L}_\Sigma(s, s, \chi)}{s} \bigg|_{s=0} \) equals
\[
\frac{\mathcal{L}_\Sigma(s, s, \chi)}{s} \bigg|_{s=0} = \frac{2\mathcal{L}_\Sigma(s, 0, \chi) - \mathcal{L}_\Sigma(s, s, \chi)}{s} \bigg|_{s=0} = 2\eta_\Sigma(Fr_{\mathfrak{P}_1})\mathcal{L}_\Sigma^{\ast\ast}(0, \chi) - \mathcal{L}_\chi^{ac}\mathcal{L}_\Sigma^{\ast\ast}(s, \chi) = \mathcal{L}_\chi \cdot \mathcal{L}_\Sigma^{\ast\ast}(0, \chi).
\]

This completes the proof of our main theorem. \( \square \)

6.3. Non-vanishing of \( \mathcal{L}_\Sigma^{\ast\ast}(0, \chi) \). We study the non-vanishing of \( \mathcal{L}_\Sigma^{\ast\ast}(0, \chi) \) via the one-sided divisibility of Iwasawa main conjecture for CM fields in [Hsi14a].

**Proposition 6.6.** Let \( \chi \) be a non-trivial ray class character of prime-to-\( p \) order. Suppose that \( (\chi, K, p) \) satisfies the assumptions \( (H1) \) and \( (H2) \) in the introduction. If the \( \Sigma \)-Leopoldt conjecture \( (\Sigma\text{-Leo}) \) is valid, then \( \mathcal{L}_\Sigma^{\ast\ast}(0, \chi) \neq 0 \).

**Proof.** This can be deduced from the one-sided divisibility result in Iwasawa main conjecture for the improved Katz \( p \)-adic \( L \)-function \( \mathcal{L}_\Sigma^{\ast\ast}(\chi) \). To begin with, let \( K_{\infty} \) be the \( \mathbb{Z}_p^{\infty+1} \)-extension of \( K \) and for any \( K_{\infty}/L/K \), put \( \Lambda(L) := \mathcal{W}[[\text{Gal}(L/K)]] \). If \( L_2 \subset L_1 \), then let \( \Lambda(L_1) \to \Lambda(L_2) \) be the surjection induced by \( \text{Gal}(L_1/K) \to \text{Gal}(L_2/K) \). Let \( S \) be the union of the set of finite places of \( K \) where \( \chi \) is ramified and the set of places above \( p \). Define the universal character \( \chi : G_{K,S} \to \Lambda(K_{\infty}) \), \( \sigma \to \chi(\sigma)[\sigma] \). Let \( \Lambda(L)^\ast = \text{Hom}_{cts}(\Lambda(L), \mathbb{Q}_p/\mathbb{Z}_p) \) be the Pontryagin dual of \( \Lambda(L) \) endowed with \( \Lambda(L) \)-module structure given by \( \lambda \cdot f(x) = f(\lambda x) \) for \( \lambda, x \in \Lambda(L) \). Let \( \chi \otimes \Lambda(L)^\ast \) be the discrete \( \Lambda(L) \)-module \( \Lambda(L)^\ast \) with the Galois action via the character \( \chi \). Define the Selmer group
\[
\text{Sel}_L(\chi) := \ker \left\{ H^1(K_S/K, \chi \otimes \Lambda(L)^\ast) \to \prod_{w \in \Sigma \setminus \chi} H^1(I_w, \chi \otimes \Lambda(L)^\ast)^{D_w} \right\}.
\]
where \( I_w \) and \( D_w \) denote the inertia and decomposition groups of \( w \). Then \( \text{Sel}_L(\chi) \) are discrete and co-finitely generated \( \Lambda(L) \)-modules. Let \( \text{char}_{\Lambda(L)}\text{Sel}_L(\chi) \) be the characteristic ideal of the Pontryagin dual \( \text{Sel}_L(\chi)^\ast \) in \( \Lambda(L) \).

Let \( L \) be the compositum of the cyclotomic \( \mathbb{Z}_p \)-extension and \( K_{\Sigma_p} \). Since \( H^0(K, \chi \otimes \Lambda(K_{\infty})^\ast) = \{0\} \) and \( L \) contains the cyclotomic \( \mathbb{Z}_p \)-extension, we have
\[
(6.17) \quad \text{Sel}_{K_{\Sigma_p}}(\chi)^\ast \otimes_{\Lambda(K_{\Sigma_p})} \Lambda(L) \sim \text{Sel}_L(\chi)^\ast
\]
is pseudo-isomorphic of finitely generated \( \Lambda(L) \)-modules in view of [Hsi14a, Remark 8.4]. Let \( I \) be the kernel of the natural quotient map \( \Lambda(L) \to \Lambda(K_{\Sigma_p}) = \Lambda_K \). We have the exact sequence
\[
0 \to \text{Sel}_{K_{\Sigma}}(\chi) \to \text{Sel}_L(\chi)[I] \xrightarrow{\text{loc}_{\Sigma_p}} \prod_{w \in \Sigma_p} \left( H^0(I_w, \chi \otimes \Lambda(L)^\ast) \otimes_{\Lambda(L)} \Lambda_K \right)^{D_w}.
\]
Taking Pontryagin dual of the above exact sequence, we find that
\[
(6.18) \quad \prod_{\mathfrak{p} \in \Sigma_p} \frac{\Lambda_K}{(1 - \chi(\mathfrak{p}))|\text{Fr}_{\mathfrak{P}}|} \to \text{Sel}_L(\chi)^\ast \otimes_{\Lambda(L)} \Lambda_K \to \text{Sel}_{K_{\Sigma}}(\chi)^\ast \to 0.
\]
Recall that \([\Fr_p] \in \Lambda_K\) is the image of the Frobenius at \(\Fr\) in \(\text{Gal}(K_{\Sigma_p}/K) \hookrightarrow \Lambda_K\) and \([\Fr_p] \neq 1\) by the ordinary assumption. The equation (6.18) implies that
\[
\prod_{\Fr \in \Sigma_p} (1 - \chi(\Fr))[\Fr_p] \cdot \text{char}_{\Lambda_K}(Sel_{K_{\Sigma_p}}(\chi)^*) \subset \text{char}_{\Lambda_K}(Sel_L(\chi)^* \otimes_{\Lambda(K_\infty)} \Lambda_K).
\]
Combined with (6.17), we get
\[
\prod_{\Fr \in \Sigma_p} (1 - \chi(\Fr))[\Fr_p] \cdot \text{char}_{\Lambda_K}(Sel_{K_{\Sigma_p}}(\chi)^*) \subset \text{char}_{\Lambda(K_\infty)}(Sel_{K_\infty}(\chi)^* \otimes_{\Lambda(K_\infty)} \Lambda_K)
\]
\(\subset \text{char}_{\Lambda(K_\infty)}(Sel_{K_\infty}(\chi)^* \otimes_{\Lambda(K_\infty)} \Lambda_K).
\]
On the other hand, by [Hsi14a, Theorem 2],
\[
\text{char}_{\Lambda(K_\infty)}(Sel_{K_\infty}(\chi)^*) \subset \mathcal{L}(\chi)\Lambda(K_\infty).
\]
By Theorem 4.9 it follows that
\[
\prod_{\Fr \in \Sigma_p} (1 - \chi(\Fr))[\Fr_p] \cdot \text{char}_{\Lambda_K}(Sel_{K_{\Sigma_p}}(\chi)^*) \subset \mathcal{L}(\chi)\Lambda_K = \prod_{\Fr \in \Sigma_p} (1 - \chi(\Fr))[\Fr_p] \cdot \mathcal{L}(\chi)\Lambda_K,
\]
and hence
\[
(6.19) \quad \text{char}_{\Lambda_K}(Sel_{K_{\Sigma_p}}(\chi)^*) \subset \mathcal{L}(\chi)\Lambda_K.
\]
Note that
\[
H^0(I_{\Sigma}, \chi \otimes \Lambda_K^*) \otimes \Lambda_K/(X) = \{0\} \text{ for all } w \in S \setminus \Sigma_p.
\]
By [Hsi14a, Lemma 8.3], this implies that
\[
(6.20) \quad Sel_{K_{\Sigma_p}}(\chi)^*/\Lambda_K(\chi)/(X) \simeq H^1_{(\emptyset, f)}(\Sigma, \chi \otimes \mathbb{Z}_p, Q_p/\mathbb{Z}_p)^*.
\]
By the Poitou-Tate duality, \(H^1_{(\emptyset, f)}(\Sigma, \chi^{-1}(1))\) and \(H^1_{(\emptyset, f)}(\Sigma, \chi \otimes Q_p/\mathbb{Z}_p)^*\) have the same rank, so the \(\Sigma\)-Leopoldt conjecture implies that \(H^1_{(\emptyset, f)}(\Sigma, \chi \otimes Q_p/\mathbb{Z}_p)^*\) is a finite group. Therefore, from (6.20), we deduce that the characteristic ideal of \(Sel_{K_{\Sigma_p}}(\chi)^*\) is not divisible by \(\chi\), and by (6.19),
\[
\mathcal{L}(\chi)(\mod X) = \mathcal{L}(\chi)(0, \chi) \neq 0.
\]
This completes the proof.

The following is an immediate consequence of Corollary 6.5 and Proposition 6.6.

**Corollary 6.7.** Let \(\chi\) be a non-trivial anticyclotomic ray class character of \(K\) such that
\[
(1) \ (\chi, K, p) \text{ satisfies the assumptions } (H1) \text{ and } (H2),
(2) \ (F-Leo) \text{ and } (\Sigma-Leo) \text{ both hold.}
\]
Then
\[
\text{ord}_{s=0} L_{\Sigma}(s, \chi) = 1 \text{ if and only if } r_{\Sigma}(\chi) = 1 \text{ and } \mathcal{L}_\chi \neq 0.
\]

**Remark 6.8.** One can also deduce the one side implication that if \(r_{\Sigma}(\chi) = 1\) and \(\mathcal{L}_\chi \neq 0\), then \(\text{ord}_{s=0} L_{\Sigma}(s, \chi) = 1\) from [BS21, Theorem 3.27] combined with [Hsi14a, Theorem 2] and the existence of the trivial zeros.

7. **Explicit calculations in the Rankin-Selberg convolution**

This section is devoted to the proof of Theorem 5.3.
7.1. Adelic Hilbert modular forms. Let \( k \) be any integer. Let \( \omega \) be a Hecke character of \( F \) of finite order. Let \( \mathcal{A}_k(\omega) \) denote the space of automorphic forms of weight \( k \) and central character \( \omega \), consisting of smooth and slowly increasing functions \( \varphi : \text{GL}_2(F) / \text{GL}_2(A_F) \rightarrow \mathbb{C} \) such that

\[
\varphi(gu_\infty z) = \omega(z)\varphi(g)J(u_\infty, \sqrt{-1})^{-k}z, \quad z \in \mathbb{A}_F^\times, \ u_\infty \in \text{SO}_2(F \otimes \mathbb{Q} \ R).
\]

Let \( \mathcal{A}_k(\omega)^0 \subset \mathcal{A}_k(\omega) \) be the subspace of cusp forms. For any integral ideal \( n \) of \( F \), put

\[
U_1(n) = \left\{ g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{GL}_2(\mathbb{A}) \mid c \in n\mathbb{A}, \ d - 1 \in n\mathbb{A} \right\}.
\]

Let \( \mathcal{A}_k(n, \omega) \) be the subspace of \( \mathcal{A}_k(\omega) \) right invariant by \( U_1(n) \). For any \( \varphi \in \mathcal{A}_k(n, \omega) \), the Whittaker function \( \psi : \text{GL}_2(A_F) \rightarrow \mathbb{C} \) of \( \varphi \) is defined by

\[
\psi(g) := \int_{\mathbb{A}/A_F} \varphi(\begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix}g) \psi_F(-x) dx.
\]

To any Hilbert modular form \( f \in M_k(n, \omega) \), we can associate a unique automorphic form in \( \varphi_f \in \mathcal{A}_k(n, \omega) \) such that for every \( y \in (F \otimes \mathbb{R})^\times \) and \( a \in \mathbb{F}^\times \), we have

\[
W_{\varphi_f}(\begin{pmatrix} ya & 0 \\ 0 & 1 \end{pmatrix}) = C(\alpha_0, f) \cdot |ya|^\frac{k}{2} e^{-2\pi \text{Tr}(y)} I_{(F \otimes \mathbb{R})^+}(y).
\]

On the other hand, a Hilbert modular form \( f \) is given by an \( h \)-tuple

\[
f = (f_{c_1}, \ldots, f_{c_h}), \quad f_{c_i} \in M_k(c_i, U_1(n)).
\]

Then we have

\[
f_{c_i}(\tau) = y^{-k_2} \varphi_f(\begin{pmatrix} y & x \\ 0 & 1 \end{pmatrix} \begin{pmatrix} c_i & 0 \\ 0 & 1 \end{pmatrix}) \ (Nc_i)^\frac{k}{2} \ (x = \sqrt{-1}y \in \mathcal{H}_F).
\]

Then

\[
C(\beta c_i, f) = c_\beta(f_{c_i}), \quad C_i(0, f) = c_0(f_{c_i}).
\]

If \( f \in S_k(n, \omega) \) is a Hilbert cuspidal newform of conductor \( n \), then denote by \( \pi_f \) the unitary and irreducible automorphic representation of \( \text{GL}_2(A_F) \) generated by \( \varphi_f \). This representation \( \pi_f \) is discrete series at all infinite places and has conductor \( n \) and central character \( \xi \). Moreover, \( \varphi_f \) is the new vector in \( \pi_f \) and

\[
L(s, \pi_f) = \Gamma_C(s + k - 1) |F:Q| D(s + \frac{k - 1}{2}, \mathfrak{f}),
\]

where \( L(s, \pi_f) \) is the automorphic \( L \)-function associated with \( \pi_f \) by Jacquet and Langlands.

7.2. Eisenstein series. The aim of this subsection is to realize the weight \( k \) specialization \( \nu_k(\mathcal{E}(m, l)) \) of the \( \Lambda \)-adic Eisenstein series \( \mathcal{E}(m, l) \) as adic Eisenstein series in \( \mathcal{E}(m, l) \) Chapter V]. For each place \( v \), let \( \omega_F(v) \) be the local component of the Teichmüller character \( \omega_F \) at \( v \). Let \( \mathcal{D} \) be the pair

\[
\mathcal{D} = (k, m, m_0),
\]

where \( k \) is a positive integer, and \( m \subset m_0 \) are integral ideals of \( F \) such that \( (m, \mathfrak{p}v) = 1 \) and \( (m_0, \mathfrak{p}_F) = 1 \). Define \( \Phi_{D} = \otimes_{v \in \mathfrak{S}} \Phi_{D,v} \otimes'_{v \in \mathfrak{h}} \Phi_{D,v} \in \mathcal{S}(\mathbb{A}_F^\times) \) by

- \( \Phi_{D,v}(x, y) = 2^{-k}(x + \sqrt{-1}y)^k e^{-\pi(x^2 + y^2)} \) if \( v \nmid \infty \),
- \( \Phi_{D,v}(x, y) = \mathbb{I}_{m_0v}(x) \mathbb{I}_v(y) \) if \( v \mid \mathfrak{p}m_0 \infty \),
- \( \Phi_{D,v}(x, y) = \mathbb{I}_{m_0v}(x) \mathbb{I}_{v^\times}(y) \) if \( v \mid m_0 \).
• \( \Phi_{D,v}(x,y) = \omega_{F_v}^{l}(x) \xi_{e_v}(x) \xi_{p_v}(y) \) if \( v \mid p \).

Let \( f_{\Phi_{D,v}} = \otimes_v f_{\Phi_{D,v,s}} \in I(\omega^k F, 1, s) \), where

(7.3) \( f_{\Phi_{D,v,s}}(g) = \omega_{F_{v}}^{k} \det(g) \int_{F_{v}^0} \Phi_{D,v}((0, t_v)g) \omega_{F_{v}}^{k}(t_v) |t_v|_{v}^{2s+1} d^x t_v. \)

Consider the adelic Eisenstein series \( E_A(g, f_{\Phi_{D,v,s}}) \) defined by (4.3). It is easy to verify that \( E_A(g, f_{\Phi_{D,v,s}}) \) is an automorphic form in \( A_k(m, \omega^k F) \) whenever it is defined. For \( \tau = x + \sqrt{-1}y \in \mathfrak{h}_F \) and \( c = c_0 \) for \( c \in \hat{F}^{(pm)^\times} \), put

\[
E_c(\tau) := y^{-\frac{k}{2}} E_A( y \begin{pmatrix} x & 0 \\ 0 & 1 \end{pmatrix}, f_{\Phi_{D,v,s}}) |c_v|^{-\frac{k}{2}}.
\]

Let \( E_k(m, m_0) = (E_{c_1}, \ldots, E_{c_{\varphi(p)}}) \in M_k(m, \omega^k F) \). This way \( E_k(-, f_{\Phi_{D,v,s}}) \) is the automorphic form associated with \( E_k(m, m_0) \) via the relation (7.1). For any integer \( n \) coprime to \( p \), put \( \langle n \rangle := n \cdot \omega(\langle n \rangle) \).

**Proposition 7.1.** For \( k \geq 2 \), we have

\[
\nu_k(\mathcal{E}(m, m_0)) = \frac{Nm}{\langle Nm \rangle^k} \cdot E_k(m, m_0).
\]

**Proof.** As in the proof of Proposition (4.3), the \( \beta \)-th Fourier coefficient of \( E_c \) is given by

\[
c_{\beta}(E_c) = \prod_{v \in \mathfrak{h}} W_{\beta}( \begin{pmatrix} c_v & 0 \\ 0 & 1 \end{pmatrix}, f_{\Phi_{D,v,s}} ) |c_v|^{-\frac{k}{2}}.
\]

Let \( v \) be a prime \( l \). Put \( \alpha_l = Nl^{-1} \langle Nl \rangle^{k} \). If \( l \nmid m_0 \), then it is easy to see that

\[
W_{\beta}( \begin{pmatrix} c_v & 0 \\ 0 & 1 \end{pmatrix}, f_{\Phi_{D,v,s}} ) |s|_{\mathfrak{o}_v}^{\frac{k}{2}} = |c_v|^{\frac{k}{2}} \sum_{i = v(m)} \alpha_l^i \text{ if } l \nmid pm_0,
\]

\[
W_{\beta}(1, f_{\Phi_{D,v,s}}) = \mathbb{I}_{\omega_s} (\beta) \text{ if } l \mid p.
\]

For \( l \mid m_0 \), we have

\[
W_{\beta}(1, f_{\Phi_{D,v,s}}) = \int_{F_{v}^0} \mathbb{I}_{\omega_s}(t) \mathbb{I}_{\varpi_v}(\beta t^{-1}) \omega^k(t) |t_v|^{2s} d^x t_v.
\]

Since \( \mathbb{I}_{\varpi_v} = \mathbb{I}_{\varpi_v} - |\varpi_v| \xi_{\varpi_v} \), we find that

\[
W_{\beta}(1, f_{\Phi_{D,v,s}}) = \sum_{i = v(m)} \omega_{\xi_{\varpi_v}}^{v(\beta)} |\varpi_v|^1_{v} - |\varpi_v| |\varpi_v|^{v(\beta) + 1}_{v} + \sum_{i = v(m)} |\varpi_v| |\varpi_v|^{v(\beta)} |\varpi_v|^{-1}_{v}
\]

\[
= \sum_{i = v(m)} \alpha_l^i - Nl^{-1} \sum_{i = v(m)} \alpha_l^i.
\]

Combined the above formulas, we deduce that

\[
C(a, E_k(m, 1)) = \sum_{a \subseteq b \subseteq m; \ (p,b) = 1} Nb^{-1} (b)^k = \frac{(Nm)^k}{Nm} C(a, \nu_k(\mathcal{E}(m, 1))
\]

\[
C(a, E_k(m, m_0)) = C(a, \prod_{l \mid m_0} (1 - Nl^{-1}U_l) E_k(m, 1)).
\]
We next investigate the constant terms. An elementary calculation shows that
\[
\begin{align*}
    f_{\Phi_d}((c \ 0) \\
    0 \ 1) &= 0, \\
    M f_{\Phi_d}((c \ 0) \\
    0 \ 1) |_{s=\frac{1+k}{2}} &= \frac{(Nm)^k}{2^dN^m} \cdot \zeta_F(1-k) \prod_{p \mid m} (1-Np^{k-1}) \prod_{l \mid m_0} \frac{1}{\zeta_{F_l}(1)}.
\end{align*}
\]
We obtain \( C_i(0, E_k(m, m_0)) \) equals
\[
C(a, \prod_{l \mid m_0} (1-Nl^{-1}U_l) E_k(m, 1)) = \zeta_{F,p}(1-k) \cdot \frac{(Nm)^k}{2^dN^m} \prod_{l \mid m_0} \frac{1}{\zeta_{F_l}(1)}.
\]
In particular, \( C_i(0, E_k(m, 1)) = \frac{(Nm)^k}{N^m} C_i(0, \nu_k(\mathcal{E}(m, 1))). \) Combining everything together, we conclude that
\[
E_k(m, 1) = \frac{(Nm)^k}{N^m} \nu_k(\mathcal{E}(m, 1)),
\]
\[
E_k(m, m_0) = \prod_{l \mid m_0} (1-Nl^{-1}U_l) E_k(m, 1).
\]
The proposition follows.  

7.3. **Whittaker functions.** Let \( \pi \) be an irreducible automorphic representation of \( \text{GL}_2(A_F) \) with the conductor \( n \). For each place \( v \), denote by \( \mathcal{W}(\pi_v) = \mathcal{W}(\pi_v, \psi_{F_v}) \) the Whittaker model of \( \pi_v \) with respect to \( \psi_{F_v} \). Recall that this is a space of smooth functions \( W \) on \( \text{GL}_2(F_v) \) satisfying the following properties:

- \( \mathcal{W}(\pi_v) \) is invariant for the right translation \( \rho \) of \( \text{GL}_2(F_v) \) and the resulting representation is isomorphic to \( \pi_v \);
- For each \( W \in \mathcal{W}(\pi_v) \),
  \[
  W\begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} g = \psi_{F_v}(x) W(g) \quad x \in F_v, \ g \in \text{GL}_2(F_v).
  \]
If \( v \in \Sigma \) and \( \pi_v \) is a discrete series of weight \( k_v \), let \( W_{\pi_v} \in \mathcal{W}(\pi_v) \) be the Whittaker function of minimal weight \( k_v \), i.e. the unique element in \( \mathcal{W}(\pi_v) \) such that
\[
W_{\pi_v}\begin{pmatrix} y & 0 \\ 0 & 1 \end{pmatrix} = y^{k_v} e^{-2\pi y \gamma_{R_v, \pi}(y)}.
\]
If \( v \) is a finite place of \( F \), let \( W_{\pi_v} \) be the new Whittaker function in \( \mathcal{W}(\pi_v, \psi_{F_v}) \), i.e. \( W_{\pi_v} \) is the unique Whittaker function right invariant by \( U_1(n) \) with \( W_{\pi_v}(1) = 1 \). If \( \pi_v \) is a principal series and \( \alpha : F_v^\times \to \mathbb{C}^\times \) is a character, we let \( W_{\pi_v}^{(\alpha)} \) be the unique Whittaker function in \( \mathcal{W}(\pi_v) \) such that
\[
W_{\pi_v}^{(\alpha)}\begin{pmatrix} a & 0 \\ 0 & 1 \end{pmatrix} = \alpha(a) |a|^{\frac{k_v}{2}} \mathbb{I}_{\pi_v}(a).
\]

7.4. **The bilinear pairing.** Let \( f \in \text{Sk}_1(np, \omega) \) be a \( p \)-stabilized cuspidal Hilbert newform of weight \( k_1 \Sigma \). Let \( \pi_F \) be the cuspidal automorphic representation generated by \( \varphi_F \). Let \( n \) be the conductor of \( \pi_F \). Assume that
\[
(p, n \Delta_F) = 1.
\]
For each \( v \mid p \), let \( \pi_{f,v} = \pi(\alpha_{f,v}, \beta_{f,v}) \) be a principal series associated with unramified characters \( \alpha_{f,v}, \beta_{f,v} : F_v^\times \to C^\times \). The Whittaker function \( W_{\varphi_f} \) has a factorization

\[
W_{\varphi_f} = \prod_{v \mid p} W_{\pi_v}^{(\alpha_{f,v})} \prod_{v \mid \infty} W_{\pi_v} \prod_{v \not= \infty} W_{\pi_v}^{(\beta_{f,v})} (\pi_v = \pi_{f,v}).
\]

Put

\[
S_v = \{ v : \text{places dividing } n \mid L(s, \pi_{f,v}) = 1 \}.
\]

Denote by \( \pi_f^\vee \) the contragredient of \( \pi_f \). Let \( \varphi_f \) be the automorphic form in \( \pi_f^\vee \) with the Whittaker function given by

\[
W_{\varphi_f} = \prod_{v \mid p} W_{\pi_v}^{(\beta_{f,v})} \cdot \prod_{v \mid \infty} W_{\pi_v} \prod_{v \not= \infty} W_{\pi_v}^{(\alpha_{f,v})} (\pi_v = \pi_{f,v}).
\]

Note that \( W_{\pi_v}^{(\beta_{f,v})} = W_{\pi_v}^{(\alpha_{f,v})} \cdot \omega_v^{-1} \). Define the \( C \)-linear pairing \( (\cdot, \cdot) : A_{n,k_1}(\omega) \times A_{k_1}(\omega^{-1}) \to C \) by

\[
(\varphi_1, \varphi_2) = \int_{PGL_2(F) \backslash PGL_2(A_F)} \varphi_1(g)\varphi_2(g)d^1g.
\]

Here \( d^1g \) is the Tamagawa measure of \( PGL_2(A_F) \). Let \( n \) be a positive integer. Put \( J_\infty = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} \in GL_2(F \otimes R); \ t_n = \begin{pmatrix} 0 & 1 \\ -p^n & 0 \end{pmatrix} \in GL_2(F \otimes Q_p) \).

**Proposition 7.2.** We have

\[
\langle \rho(J_\infty t_n) \varphi_f, \varphi_f \rangle = \frac{2L(1, \pi_f, Ad)}{\sqrt{\Delta_F} \zeta_F(2)} \cdot \frac{1}{2^{(k_1+1)|F:Q|}} \prod_{v \mid n} \frac{\zeta_{F_v}(2)}{\zeta_{F_v}(1)}
\]

\[\times \prod_{v \in S_v} \frac{1}{L(1, \pi_v, Ad)} \prod_{v \mid p} \frac{\omega_v^{-1} \alpha_{f,v}^{-1} |p_f^{-1} \beta_{f,v}^{-1} | \zeta_{F_v}(2)}{\zeta_{F_v}(1)} \cdot E_v(Ad_f),\]

where \( E_v(Ad_f) \) is the modified \( p \)-Euler factor for the adjoint of \( f \) given by

\[
E_v(Ad_f) = L(1, \alpha_{f,v}^{-1} \beta_{f,v}^{-1})^{-1} L(0, \alpha_{f,v}^{-1} \beta_{f,v}^{-1})^{-1} (1 - \alpha_{f,v}^{-1} \beta_{f,v}^{-1} (p) |p_f^{-1} \beta_{f,v}^{-1} (p)).
\]

**Proof.** For each place \( v \), let \( \langle \cdot, \cdot \rangle : \mathcal{W}(\pi_v) \times \mathcal{W}(\pi_v^\vee) \to C \) be the pairing defined by

\[
\langle W_1, W_2 \rangle = \int_{F_v^\times} W_1(\begin{pmatrix} a_v & 0 \\ 0 & 1 \end{pmatrix})W_2(\begin{pmatrix} -a_v & 0 \\ 0 & 1 \end{pmatrix})d^x a_v^\times \}
\]

where \( d^x a_v^\times \) is the Haar measure on \( F_v^\times \) with vol\((a_v^\times, d^x a_v^\times) = 1 \). It follows from [Wal85 Proposition 6] that

\[
\langle \rho(J_\infty t_n) \varphi_f, \varphi_f \rangle = \frac{2L(1, \pi, Ad)}{\sqrt{\Delta_F} \zeta_F(2)} \cdot 2^{-(k_1+1)|F:Q|} \prod_{v \mid n} \frac{\zeta_{F_v}(2)}{\zeta_{F_v}(1)} L(1, \pi_v, Ad)
\]

\[\times \prod_{v \mid p} \frac{\zeta_{F_v}(2)}{\zeta_{F_v}(1)} \cdot \langle \rho(t_n) W_{\pi_v}^{(\alpha_{f,v})}, W_{\pi_v}^{(\beta_{f,v})} \cdot \omega_v^{-1} \rangle.
\]
For \( v \mid n \), it is well-known that

\[
\frac{\langle W_{\pi_v}, W_{\pi_v'} \rangle}{L(1, \pi_v, \text{Ad})} = \begin{cases} 1 & \text{if } v \notin S_{\text{tr}}, \\ \frac{1}{\zeta(1, \pi_v, \text{Ad})} & \text{if } v \in S_{\text{tr}}. \end{cases}
\]

The local integral at primes above \( p \) is computed in [Hsi21, Lemma 2.8]

\[
\langle \rho(t_n)W_{\pi_\mathfrak{v}}^{(\alpha_\mathfrak{v}, \omega)} , W_{\pi_\mathfrak{v}}^{(\alpha_\mathfrak{v}, \omega)} \otimes \omega^{-1} \rangle = \omega_v^{-1} \alpha_{\mathfrak{v}, \mathbb{C}}^2 |\mathfrak{v}|_v \cdot (p^n) \cdot \gamma(0, \alpha_{\mathfrak{v}, \mathbb{C}}^{-1} \beta_{\mathfrak{v}, \mathbb{C}}) \zeta_{\mathfrak{v}, \mathbb{C}}(1),
\]

where

\[
\gamma(0, \alpha_{\mathfrak{v}, \mathbb{C}}^{-1} \beta_{\mathfrak{v}, \mathbb{C}}) = \frac{|\mathfrak{d}_{\mathfrak{v}}|_{\mathfrak{v}}^{-\frac{1}{2}} L(1, \alpha_{\mathfrak{v}, \mathbb{C}}, \beta_{\mathfrak{v}, \mathbb{C}}^{-1})}{L(0, \alpha_{\mathfrak{v}, \mathbb{C}}, \beta_{\mathfrak{v}, \mathbb{C}}^{-1})}.
\]

This finishes the proof.

7.5. Rankin-Selberg convolution. We keep the notation in the previous subsection. Let \( \pi_1 = \pi_F \). Let \( g^0 \in \mathcal{S}_k(n, \omega^{-1}) \) be a Hilbert cuspform of parallel weight \( k_2 < k_1 \). Let \( \pi_2 \) be the cuspidal automorphic representation generated by \( \varphi_{g^0} \). Assume that

(RS1) \( k_1 - k_2 \) is divisible by \( p - 1 \);  
(RS2) for every \( v \mid n \), \( \pi_{2, v} \) is isomorphic to \( \pi_{1, v} \) up to unramified twists.

We put

\[
S_0 = \{ v : \text{places dividing } n \mid \pi_{1, v} \text{ is minimal} \},
\]

\[
S_{\text{dis}} = \{ v \in S_0 \mid \pi_{1, v} \text{ is a discrete series} \}.
\]

Here recall that we say \( \pi_{1, v} \) is minimal if the conductor of \( \pi_{1, v} \) is minimal among that of its twists by a character. We define

\[
(7.7) \quad n = \prod_q q^{a_q}, \quad m = \prod_{q \notin S_{\text{dis}}} q^{e_q} \prod_{q \in S_{\text{dis}}} q^{\left[\frac{a_p}{2}\right]}; \quad m_0 = \prod_{q \notin S_0} q.
\]

Let \( S_p^{\text{reg}} \) be a subset of \( S_p \), the set of prime factors of \( p \). Suppose that the automorphic form \( \varphi_{g^0} \) associated with \( g^0 \) admits the Whittaker function

\[
(7.8) \quad W_{\pi_{g^0}} = \prod_{v \notin S_p^{\text{reg}}} W_{\pi_{2, v}} \prod_{v \in S_p^{\text{reg}}} W^{(\alpha_{g^0})}_{\pi_{2, v}}.
\]

Proposition 7.3. With the assumptions (RS1-2) and \( \mathcal{D} = (k_1 - k_2, m, m_0) \), we have

\[
\langle \rho(\mathcal{T}_n t_n) \varphi_{\mathbb{F}_\mathfrak{v}}, \varphi_{\mathbb{F}_\mathfrak{v}} \rangle \cdot E_A(-, f_{\mathbb{F}_0, \mathbb{F}_{-1/2}}) = (\sqrt{-1})^{(k_1 - k_2) [F: \mathbb{Q}]} L(s, \pi_1 \times \pi_2) \times \frac{1}{2L(1, \pi_1, \text{Ad})} \\
\frac{1 \prod_{v \mid m_0} L(1, \pi_{1, v}, \text{Ad}) \prod_{v \in S_p} E_v(\text{ad} f)L(s, \pi_2 \otimes \beta_{\mathfrak{v}, \mathbb{C}}) \prod_{v \in S_p^{\text{reg}}} L(1 - s, \alpha_{\mathfrak{v}, \mathbb{C}}^{-1})}{L(s, \pi_1, \pi_2) \prod_{v \in S_p^{\text{reg}}} L(1 - s, \alpha_{\mathfrak{v}, \mathbb{C}}^{-1})}.
\]

Proof. Let \( N \) be the unipotent upper triangular subgroup of \( \text{GL}_2 \). For each place \( v \), define the bilinear form \( \Psi : \mathbb{H}(\pi_{1, v}) \times \mathbb{H}(\pi_{2, v}) \times \mathbb{I}(1, v, s) \rightarrow \mathbb{C} \) by

\[
\Psi(W_1, W_2, f) = \int_{\text{N}(\mathbb{F}_v) \backslash \text{PGL}_2(\mathbb{F}_v)} W(g_v)W_2\left(\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} g_v \right)f(g_v)dg_v,
\]

where \( dg_v \) is the Haar measure given by

\[
\int_{\text{N}(\mathbb{F}_v) \backslash \text{PGL}_2(\mathbb{F}_v)} F(g_v)dg_v = \int_{\text{GL}_2(\mathbb{F}_v)} \int_{\mathbb{F}_v^n} F(S) F(\begin{pmatrix} a_v \\ 0 \\ 0 \\ 1 \end{pmatrix})|a_v|^{-1} d^{n+1} a_v^* dv_v.
\]
with $\text{vol}(\text{GL}_2(\mathfrak{o}_v), dw_v) = 1$. According to \cite[Chapter V]{Jac72} (cf. \cite[(5.11)]{CH20}), we have the basic identity

$$\langle \rho(\mathcal{J}_{\infty} t_n) \varphi_{\mathfrak{F}}, \varphi_{g^*} \cdot E_{\mathfrak{A}}(-, f_{\Phi_{D,v},s-\frac{1}{2}}) \rangle = \int_{\text{PGL}_2(F) \backslash \text{GL}_2(A_F)} \varphi_{\mathfrak{F}}(g) E_{\mathfrak{A}}(g, f_{\Phi_{D,v},s-\frac{1}{2}}) \text{d}g$$

\[ = \frac{1}{\sqrt{\Delta_F} \zeta_F(2)} \prod_{v \mid \infty} \Psi(\rho(\mathcal{J}_{\infty}) W_{\pi_{1,v}, W_{\pi_{2,v}}, f_{\Phi_{D,v},s-\frac{1}{2}}}) \prod_{v \mid p \infty} \Psi(W_{\pi_{1,v}, W_{\pi_{2,v}}, f_{\Phi_{D,v},s-\frac{1}{2}}}) \times \prod_{v \mid p} \Psi(W_{\pi_{1,v}, W_{\pi_{2,v}}, f_{\Phi_{D,v},s-\frac{1}{2}}}^\text{ord}).\]

For each place $v$, let $L(s, \pi_{1,v} \times \pi_{2,v})$ be the local Rankin-Selberg $L$-function for $\pi_{1,v} \times \pi_{2,v}$. If $v \in \mathfrak{h}$ and $v \nmid \mathfrak{p} n$, 

$$\Psi(W_{\pi_{1,v}, W_{\pi_{2,v}}, f_{\Phi_{D,v},s-\frac{1}{2}}}) = L(s, \pi_{1,v} \times \pi_{2,v})$$

by \cite[Proposition 15.9]{Jac72}, and if $v \mid \infty$, it is computed in \cite[Proposition 5.3]{CH20} that

$$\Psi(\rho(\mathcal{J}_{\infty}) W_{\pi_{1,v}, W_{\pi_{2,v}}, f_{\Phi_{D,v},s-\frac{1}{2}}}) = (\sqrt{-1})^{k_1 - k_2} 2^{-k_1 - 1} L(s, \pi_{1,v} \times \pi_{2,\infty}).$$

Therefore, we find that

$$\langle \rho(\mathcal{J}_{\infty} t_n) \varphi_{\mathfrak{F}}, \varphi_{g^*} \cdot E_{\mathfrak{A}}(-, f_{\Phi_{D,v},s-\frac{1}{2}}) \rangle = \frac{L(s, \pi_{1} \times \pi_{2})}{\sqrt{\Delta_F} \zeta_F(2)} \left( \frac{(\sqrt{-1})^{(k_1 - k_2)}}{2^{k_1 + 1}} \right) \prod_{v \mid \mathfrak{p} n} \Psi_v(s),$$

where $\Psi_v(s)$ are the local zeta integrals defined by

$$\Psi_v(s) = \begin{cases} \frac{\Psi(W_{\pi_{1,v}, W_{\pi_{2,v}}, f_{\Phi_{D,v},s-1/2}})}{L(s, \pi_{1,v} \times \pi_{2,v})} & \text{if } v \mid \mathfrak{n}, \\ \frac{\Psi(\rho(t_v) W_{\pi_{1,v}, f_{\Phi_{D,v},s-1/2}})}{L(s, \pi_{1,v} \times \pi_{2,v})} & \text{if } v \mid p; v \not\in S_p^\text{reg}, \\ \frac{\Psi(\rho(t_v) W_{\pi_{1,v}, f_{\Phi_{D,v},s-1/2}})}{L(s, \pi_{1,v} \times \pi_{2,v})} & \text{if } v \in S_p^\text{reg}. \end{cases}$$

We first consider the integrals $\Psi_v(s)$ for $v \mid \mathfrak{n}$. Put

$$S_1 = \{ v \in S_{\text{dis}} \mid \pi_{1,v} \text{ is supercuspidal and } \pi_{1,v} \simeq \pi_{1,v} \otimes \tau_{F_{\mathfrak{p}^2}/F_v} \}.$$ 

The integrals $\Psi_v(s)$ for $v \in S_0$ have been evaluated in \cite[Lemma 6.3, 6.5]{CH20}, and we obtain

$$\Psi_v(s) = \begin{cases} \frac{\zeta_{F_v}(2)}{\zeta_{F_v}(1)} & \text{if } v \not\in S_1, \\ (1 + N_v^{-1}) & \text{if } v \in S_1. \end{cases}$$

If $v \not\in S_0 \iff v \mid m_0$, then $\pi_{1,v}$ is not minimal and $|n_v| = |m_v|$. In this case, 

$$W_{\pi_{1,v}} \left( \begin{array}{cc} a & 0 \\ 0 & 1 \end{array} \right) = I_{\mathfrak{a}_v} \left( \begin{array}{c} a \\ x \end{array} \right) \text{ for } i = 1, 2 \text{ and}$$

$$f_{\Phi_{D,v},s}(u) = \mathbb{I}_{L_0(n)_v}(u) \text{ for } u \in \text{GL}_2(\mathfrak{o}_v).$$
A direct calculation shows that
\[
\Psi(W_{\pi_1,v}, W_{\pi_2,v}, f_{\Phi_{D,v},s-1/2}) = \text{vol}(U_0(n)_v, d\gamma_v) = \frac{|n|_v \zeta_{F_v}(2)}{\zeta_{F_v}(1)};
\]
\[
\Psi_v(s) = \frac{|n|_v \zeta_{F_v}(2)}{\zeta_{F_v}(1)L(s, \pi_{1,v} \times \pi_{2,v})}.
\]

We next compute the local zeta integral \(\Psi_v(s)\) for \(v \in S_p\) by a similar calculation in \([CH20\text{ Lemma 6.1}].\) Put \(W_1 = W_{\pi_1,v}^{(n)}\) and \(W_2 = W_{\pi_2,v}\) if \(v \not\in S_p^{\text{reg}}\) or \(W_{\pi_2,v}^{(\alpha_v)}\) if \(v \in S_p^{\text{reg}}.\) Then \(\Psi(\rho(t_n)W_1, W_2, f_{\Phi_{D,v},s-1/2})\) equals
\[
\frac{\zeta_{F_v}(2)}{\zeta_{F_v}(1)} \int_{F_v^\times} W_1 \left( \begin{pmatrix} y & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 & -1 \\ 1 & x \end{pmatrix} t_n \right) W_2 \left( \begin{pmatrix} -y & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 & -1 \\ 1 & x \end{pmatrix} \right) |y|_v^{-s-1} \\
\times f_{\Phi_{D,v},s-1/2} \left( \begin{pmatrix} 0 & -1 \\ 1 & x \end{pmatrix} \right) dx dy \\
= \frac{\zeta_{F_v}(2)}{\zeta_{F_v}(1)} \int_{F_v^\times} W_1 \left( \begin{pmatrix} y^n & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & -p^nx \end{pmatrix} \right) W_2 \left( \begin{pmatrix} -y & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 & -1 \\ 1 & x \end{pmatrix} \right) |y|_v^{-s-1} \\
\times I_\alpha_v(x) dx dy \\
= \frac{\zeta_{F_v}(2) \omega_v^{-1}(p^n) \zeta_{F_v}(2)}{\zeta_{F_v}(1)} \frac{1}{\gamma(s, \pi_2 \otimes \alpha_{F,v})} \int_{F_v^\times} W_2 \left( \begin{pmatrix} -y & 0 \\ 0 & 1 \end{pmatrix} \right) \omega_v^{-1} \alpha_{F,v}^{-1} |y|_v^{-s} dy \\
= \frac{\omega_v^{-1} \alpha_{F,v}^{-1}}{\zeta_{F_v}(1)} \cdot L(s, \pi_2, \pi_1) \left\{ \begin{array}{l} \frac{1}{L(1-s, \alpha_v^{-1}, \alpha_{F,v})} \text{ if } v \in S_p^{\text{reg}}, \\
1 \text{ otherwise.} \end{array} \right.
\]

Here we have used the local functional equation for \(GL(2)\) in the second equality. Combining these formulas, we finally obtain
\[
\langle \rho(\mathcal{J}_{\infty} t_n) \phi_{F,v} \otimes \phi_{F,v}, E_{\mathcal{A}}(-, f_{\Phi_{D,v},s-1/2}) \rangle = \frac{L(s, \pi_1 \times \pi_2)}{\Delta_F \zeta_{F}(2)} \left( \frac{(\sqrt{-1})^k}{2(k+1)} \right)^{[F:Q]} (\sqrt{-1})^{k_1-k_2} \\
\times \frac{1}{Nm} \prod_{v \mid \mathfrak{n}} \frac{\zeta_{F_v}(2)}{\zeta_{F_v}(1)} \prod_{v \in S_0} (1 + Nu^{-1}) \prod_{v \mid m_0} \frac{1}{L(s, \pi_{1,v} \times \pi_{2,v})} \\
\times \prod_{v \mid \mathfrak{p}_v} \frac{\omega_v^{-1} \alpha_{F,v}^{-1}}{\zeta_{F_v}(1)} \cdot L(s, \pi_{2,p} \otimes \beta_{F,v}) \prod_{v \in S_{\text{reg}}} \frac{1}{L(1-s, \alpha_v^{-1}, \alpha_{F,v})}.
\]

The result follows from Proposition 7.2 and the fact that if \(v \in S_\infty \cap S_0,\) then \(v\) must be supercuspidal, and hence
\[
L(1, \pi_v, \text{Ad}) = \begin{cases} (1 + Nu^{-1})^{-1} & \text{if } v \in S_0, \\ 1 & \text{otherwise}. \end{cases}
\]

by \([GJ78\text{ Corollary (1.3)}].\) \(\blacksquare\)

7.6. **Proof of Proposition 5.3** Now we are in a position to to prove Proposition 5.3 by Hida’s \(p\)-adic Rankin-Selberg method. We shall use the representation theoretic approach in \([CH20].\) Let \(d = [F:Q].\) It suffices to show that for all but
finitely many positive integer $k$ with $k \equiv 0 \mod p^d - 1$,
$$
\varepsilon_k^{\Sigma}(C(\phi^c, \phi)) = \frac{1}{(Nm)^k} \cdot \frac{2^d \mathcal{L}_\Sigma(k, 0, 1) \mathcal{L}_\Sigma(k, 0, \chi)}{h_{K/F} \cdot \mathcal{L}_\Sigma(k, -k, \chi) \zeta_{F,p}(1 - s)} \cdot \psi(\theta_{p^k})^{-k} \cdot \prod_{\mathfrak{p} \in \Sigma_{F,p}} (1 - \psi^k(\mathfrak{p}))^2 \prod_{\mathfrak{p} \in \Sigma_{F,p}' \Sigma_{F,p}^{reg}} (1 - \psi^k(\mathfrak{p})) \cdot \text{Ex}_\nu(k).
$$
(7.9)

Here recall that $\chi = \phi^{1-c}$ is an anticyclotomic character of conductor $f_0 K$ and $\psi$ is the idele class character of $K$ corresponding to $\varepsilon_\Sigma$ with $\psi_{\infty}(z) = z$. Note that $\psi^k$ is unramified everywhere for $k$ is divisible by $p^d - 1$. To evaluate $\varepsilon_k^{\Sigma}(C(\phi^c, \phi))$, we consider the spectral decomposition
$$
epsilon_{\text{ord}}(\theta_{p^k}^\Sigma G(m, l_0)) = \frac{2^d Nm \cdot \zeta_{F,p}(1)}{(Nm)^k \zeta_{F,p}(1 - k)} \cdot \epsilon_{\text{ord}}(\theta_{p^k}^\Sigma E_k(m, l_0))
$$
(7.10)

where $\mathcal{H}_k$ is orthogonal to the space generated by $\{V_\mathfrak{p} \theta_{\phi^{1-c} \psi^{-k}}(V_\mathfrak{p} \theta_{\psi^{-k}})\}_{\mathfrak{p} \mid p}$ under the Petersson inner product. Since $\varepsilon_k^{\Sigma}(\theta_{\phi}) = \theta_{\phi^{1-c} \psi^{-k}}$ is a $p$-stabilized newform of weight $(k + 1)\Sigma$, the decomposition (7.10) is indeed obtained by the image of (5.12) under the map $\varepsilon_k^{\Sigma}$, and hence
$$\varepsilon_k^{\Sigma}(C(\phi^c, \phi)) = \iota_{p}^{-1}(C_k(\phi^c, \phi)).$$

Now we use the adelic Rankin-Selberg method to compute the value $C_k(\phi^c, \phi)$. Let $f^{\text{new}} = \theta_{\phi^{1-c} \psi^{-k}}$ and $g^{\text{new}} = \theta_\phi$ be the Hilbert newforms associated with Hecke characters $\phi^{1-c} \psi^{-k}$ and $\phi$. Let $\pi_1$ and $\pi_2$ be the cuspidal automorphic representation of $GL_2(A_F)$ associated with $\varphi_{f^{\text{new}}}$ and $\varphi_{g^{\text{new}}}$. Then $\pi_1$ and $\pi_2$ are the automorphic inductions of the idele class characters $\phi^{1-c} \psi^{-k}$ restricted to $A_k$ and $\phi$, so we see that $\pi_1$ and $\pi_2$ satisfy (RS1) and (RS2). In addition, the automorphic $L$-functions of $\pi_1$ and $\pi_2$ are given by
$$L(s, \pi_1) = \Gamma_c(s + k)^d D(s + \frac{k}{2}, f^{\text{new}}) = L(s + \frac{k}{2}, \phi^{1-c} \psi^{-k});
$$
$$L(s, \pi_2) = \Gamma_c(s)^d D(s, g^{\text{new}}) = L(s, \phi).$$

Let $f = \theta_{\phi^{1-c} \psi^{-k}}$ be the $p$-stabilized newform associated with $f^{\text{new}}$ and let $\tilde{f} := \theta_{\phi^{1-c} \psi^{-k}}$ be the specialization of $\varepsilon_k^{\Sigma}(\theta_{\phi^c})$ at $s = k$. Let $g^\circ = \theta_\phi$ be the theta series defined in (5.10). Let $v \mid p$ with $v = \mathfrak{P}^\Sigma$ and $\mathfrak{P} \in \Sigma_p$. Then $\pi_{1,v} = \pi(\alpha_{\mathfrak{r},v}, \beta_{\mathfrak{r},v})$, where $\alpha_{\mathfrak{r},v}, \beta_{\mathfrak{r},v} : F_v^\times \to C^\times$ are the unramified characters such that
$$\alpha_{\mathfrak{r},v}(p) = \phi^{1-c} \psi^{-k}(\mathfrak{P}) N\mathfrak{P}^{-\frac{k}{2}}; \quad \beta_{\mathfrak{r},v}(p) = \phi^{-1} \psi^{-k}(\mathfrak{P}) N\mathfrak{P}^{-\frac{k}{2}}.$$

Then one verifies that the Whittaker functions of $\varphi_{\mathfrak{r}}$ and $\varphi_{\phi}$ are given by (7.4) and (7.5). Likewise, $\pi_{2,v} \simeq \pi(\alpha_{\mathfrak{g},v}, \beta_{\mathfrak{g},v})$, where $\alpha_{\mathfrak{g},v}$ and $\beta_{\mathfrak{g},v}$ are unramified characters of $F_v^\times$ with $\alpha_{\mathfrak{g},v}(p) = \phi(\mathfrak{P})$ and $\beta_{\mathfrak{g},v}(p) = \phi(\mathfrak{P})$. Then one verifies that the Whittaker function of $\varphi_{\mathfrak{g}}$ is precisely given by (7.8). In the notation of previous two subsections,
- $k_1 = k + 1$ and $k_2 = 1$.
- $S_{\text{dis}}$ is the set of prime factors of $c$ and $e_q$ is even for $q \in S_{\text{dis}}$.
- $S_0$ is the set of prime factors of $n$ except for $l$, and $m_0 = 1$ in view of (min).
The ideal $\mathfrak{m}$ in (5.5) is the one introduced in (7.7).

By [CH20 Proposition 5.2], for $n \gg 0$ large enough, we have

$$C_k(\phi^c, \phi) = \frac{\langle p(\mathcal{J}_{t,n}) \phi r, \phi \rangle_{\mathbb{F}_r} \cdot E_{A}(-s, f_{A^2, s-1/2}) \rangle_{s=1-k}}{\langle p(\mathcal{J}_{t,n}) \varphi r, \varphi \rangle} \cdot \frac{2^d N \zeta_{E}(1)}{\zeta_{E,F}(1-k) \langle N \rangle^{k}}.$$ 

Note that by definition

$$\text{Ex}_l(k) = \frac{\zeta_{E}(1) L(1, \phi^{1-c} \psi(1-c)k)}{L(1, \psi^{-k}) L(1, \phi^{c-1} \psi^{-k})} = \frac{\zeta_{E}(1) L(1, \tau_{1, \text{Ad}})}{L(1 - \frac{k}{2}, \tau_{1,1} \times \tau_{2,1})}.$$ 

Put $\psi_{-} = \psi^{1-c}$. From Proposition 7.2 and Proposition 7.3 we deduce that

$$(7.11)$$

$$C_k(\phi^c, \phi) = \frac{1}{\langle N \rangle^{k}} \cdot \frac{2^{d} (\sqrt{-1})^{k} L(1, \psi^{-k}) L(1, \phi^{c-1} \psi^{-k})}{2 L(1, \tau_{1, \text{Ad}}) \zeta_{E,F}(1-k)} \times \prod_{\mathfrak{p} \in \Sigma_{p}} \frac{(1 - \psi^{-k}(\mathfrak{p}) \mathfrak{n} \mathfrak{p}^{-1})(1 - \phi^{c-1} \psi^{-k}(\mathfrak{p}) \mathfrak{n} \mathfrak{p}^{-1})}{\prod_{\mathfrak{p} \in \Sigma_{p}} (1 - \chi \psi^{-k}(\mathfrak{p})^{-1} - 1)(1 - \chi \psi^{-k}(\mathfrak{p}))} \times \text{Ex}_l(k).$$

By the functional equations of $L$-functions, one has

$$L(1, \psi^{-k}) L(1, \phi^{c-1} \psi^{-k}) = \varepsilon(1, \psi^{-k}) \varepsilon(1, \chi^{-1} \psi^{-k}) L(0, \psi^{-k}) L(0, \chi \psi^{-k}),$$

$$L(1, \tau_{1, \text{Ad}}) = L(1, \tau_{K/Q}) L(1, \phi^{1-c} \psi^{(1-c)k}) = \varepsilon(1, \chi \psi^{-k}) \cdot L(1, \tau_{K/Q}) L(0, \chi \psi^{-k}).$$

Note that $\mathfrak{o}_K$ is the conductor of $\chi$ and $\psi^{k}$ is unramified everywhere with $\psi_{-} \mid A^k = 1$, so we have

$$\varepsilon(1, \psi^{-k}) = \sqrt{\Delta_K}^{-1} \psi(\mathfrak{o}_K)^{-k}, \quad \varepsilon(1, \chi \psi^{-k}) = \varepsilon(1, \chi) \psi(\mathfrak{o}_K)^{-k},$$

$$\varepsilon(1, \chi \psi^{k}) = \varepsilon(1, \chi).$$

It follows that

$$(7.12)$$

$$\frac{\langle (\sqrt{-1})^{k} L(1, \psi^{-k}) L(1, \phi^{c-1} \psi^{-k})}{2 L(1, \tau_{1, \text{Ad}})} = \frac{(\sqrt{-1})^{k} L(0, \psi^{-k}) L(0, \chi \psi^{-k})}{2 \sqrt{\Delta_K} L(1, \tau_{K/Q}) L(0, \chi \psi^{-k})} \cdot (\mathfrak{o}_K)^{-k}.$$ 

By the interpolation formulae of the Katz $p$-adic $L$-function in (4.14), we find that

$$(7.13)$$

$$\frac{\mathcal{L}_{\Sigma}(k, 0, \chi) \mathcal{L}_{\Sigma}(k, 0, 1)}{\mathcal{L}_{\Sigma}(k, -k, \chi)} = \frac{[\mathfrak{o}_K : \mathfrak{o}_F^2]}{2^{d} \sqrt{\Delta_F} (\sqrt{-1})^{k}} \frac{L(0, \chi \psi^{k}) L(0, \psi^{-k})}{L(0, \chi \psi^{-k})} \times \prod_{\mathfrak{p} \in \Sigma_{p}} \frac{(1 - \psi^{k}(\mathfrak{p})^{-1} \mathfrak{n} \mathfrak{p}^{-1})(1 - \chi \psi^{k}(\mathfrak{p})^{-1} \mathfrak{n} \mathfrak{p}^{-1})(1 - \psi^{k}(\mathfrak{p}))^2}{(1 - \chi \psi^{-k}(\mathfrak{p})^{-1} \mathfrak{n} \mathfrak{p}^{-1})(1 - \chi \psi^{-k}(\mathfrak{p}))}.$$ 

Combining (7.11), (7.12), (7.13) and (4.8), we obtain (7.9). This finishes the proof.

**Appendix A. Transcendental number theory and non-vanishing of the $p$-adic regulators**

A.1. **The $p$-adic transcendence conjectures.** The non-vanishing of the regulators are usually tied with well-known conjectures in $p$-adic transcendental number
We first recall some standard results and conjectures in $p$-adic transcendence. As before, $\log_p : \mathbb{Q}_p^\times \to \mathbb{Q}_p$ is the Iwasawa $p$-adic logarithm with $\log_p(p) = 0$, and we use the same notation for its composition with $\iota_p : \mathbb{Q} \hookrightarrow \mathbb{Q}_p$. Denote $\tilde{L} \subset \mathbb{Q}_p$ the $\mathbb{Q}$-vector space generated by $1$ and elements of $\log_p(\mathbb{Q}_p^x)$. We recall the statements of two conjectures at the top of a Hierarchy of conjectures and theorems concerning the arithmetic nature of certain values of $\log_p$.

**Conjecture 5** (Strong Four Exponentials Conjecture). Let $M$ be a $2 \times 2$ matrix with entries in $\tilde{L}$. Assume the rows and the columns of $M$ are linearly independent over $\mathbb{Q}$ respectively. Then $M$ has rank $2$.

**Conjecture 6** ($p$-adic Schanuel’s Conjecture). Let $\alpha_1, \ldots, \alpha_n \in \mathbb{Q}^\times$ such that $\log_p(\alpha_1), \ldots, \log_p(\alpha_n)$ are linearly independent over $\mathbb{Q}$. Then $\mathbb{Q}(\log_p(\alpha_1), \ldots, \log_p(\alpha_n))$ has transcendence degree $n$ over $\mathbb{Q}$.

Remark A.1. The significance of these $p$-adic transcendental conjectures perhaps stems from their direct applications to the non-vanishing of $p$-adic regulators. Below we give some examples without details.

1. If $F$ is a real quadratic field, the Strong Four Exponentials conjecture implies that $\mathbb{R}_\Sigma(\chi) \neq 0$, i.e. the $\Sigma$-Leopoldt conjecture for $\chi$ holds.
2. The $p$-adic Schanuel conjecture implies the $\Sigma$-Leopoldt conjecture (cf. [HT94, Lemma 1.2.1]) and the non-vanishing of the $L$-invariants $L_{\chi}$ and $L_{\text{ac}}$.

A.2. **Examples of the $\Sigma$-Leopoldt conjecture.** Notation is as in the introduction. Recall that $\chi$ is a ray class character of a CM field $K$ and $H$ is the abelian extension over $K$ cut out by $\chi$. We give examples of $(\chi, K, \Sigma, p)$ such that $\Sigma$-Leopoldt conjecture for $\chi$ holds, i.e., Conjecture 2 (or equivalently (\Sigma-Leo) holds).

The following famous Baker-Brumer Theorem is the best result towards these conjectures in the current literature.

**Theorem A.2** (Baker–Brumer [Bru67]). Let $\lambda_1, \ldots, \lambda_n \in \mathbb{L}$ are linearly independent over $\mathbb{Q}$, then they are linearly independent over $\overline{\mathbb{Q}}$.

**Corollary A.3.** Suppose that $K = FM$ for an imaginary quadratic field $M$ in which $p$ splits and $H/M$ is abelian. Suppose also that the CM type $\Sigma$ of $K$ is obtained by extending the CM type of $M$, i.e. a choice of embeddings $\iota : M \hookrightarrow \mathbb{C}$. Then the $\Sigma$-Leopoldt conjecture for $\chi : \text{Gal}(H/K) \to \mathbb{Q}_p^\times$ holds.

**Proof.** By the Dirichlet unit theorem (cf. [NSW08, Prop. 8.7.2, p.503]), there is an isomorphism $\mathbb{Q} \cong \mathbb{Q}\{\mathbb{O}_H^\times \} \cong \mathbb{Q}[\text{Gal}(H/M)]$ as $\text{Gal}(H/M)$-modules, so there exists a Minkowski unit $u \in \mathbb{O}_H^\times$, i.e. the set $\{\sigma(u)^{\chi^{-1}}\}_{\sigma \in \text{Gal}(H/M) \setminus \{1\}}$ is a basis of $\mathbb{Q}\{\mathbb{O}_H^\times \}$. Moreover, since $H/M$ is abelian and $\chi \neq 1$, we find that $H^1_{(f, f)}(K, \chi^{-1}(1)) \cong \bigoplus_{i=1}^d \mathbb{O}_H^\times[\chi_i]$ as $\text{Gal}(H/M)$-modules,
where $\chi_i$ are characters of $\text{Gal}(H/M)$ extending $\chi$ and that $\dim E \mathcal{O}_H^\chi[\chi_i] = 1$. For any character $\chi_i \neq 1$,

$$u_{\chi_i} := \sum_{\tau \in \text{Gal}(H/M)} \chi_i(\tau^{-1}) \otimes \tau(u)u^{-1} \in \mathcal{O}_H^\chi[\chi_i].$$

Then $\log_p(u_{\chi_i}) \neq 0$ by the Baker-Brumer Theorem. It follows that $\log_p : \mathcal{O}_H^\chi[\chi_i] \simeq \mathbb{Q}_p$ is an isomorphism and $\log_{\Sigma,p} : H^1_{(f,f)}(K, \chi^{-1}(1)) \simeq \mathbb{Q}_p^\chi$. \hfill $\blacksquare$

In the above example, $H$ is abelian over an imaginary quadratic field $M$, so the Katz $p$-adic $L$-function $L_p(s, \chi)$ is a product of $p$-adic $L$-functions over $M$, and the trivial zeros in this case have been studied extensively in [BS19] via the Euler system of elliptic units. To obtain more interesting examples beyond this case, we will make use of the following strong version of the Six Exponentials Theorem due to Roy [Roy92 Corollary 2]

**Theorem A.4** (Strong Six Exponentials Theorem). Let $M$ be a $2 \times 3$ matrix with entries in $\mathbb{Q}$. Assume the rows and the columns of $M$ are linearly independent over $\mathbb{Q}$ respectively. Then $M$ has rank 2.

**Proposition A.5.** Assume that $F$ is a quadratic real field in which $p$ splits and $\chi \neq \chi^c$. Then there exists a $p$-adic CM type $\Sigma$ of $K$ such that the $\Sigma$-Leopoldt conjecture holds.

**Proof.** We let $L$ be the Galois closure of $H$. Choose a $p$-adic CM type $\Sigma = \{\sigma_1, \sigma_2\}$ of $K/F$ and let $\Sigma_{L,i}$ be the subset of $\sigma \in \text{Gal}(L/Q)$ such that $\sigma|_K = \sigma_i$. Let $G_{\infty} = \{1, c\} \subset \text{Gal}(L/Q)$ be the decomposition at the archimdean place induced by $i_{\infty} : \mathbb{Q} \hookrightarrow \mathbb{C}$. By the Dirichlet unit Theorem, there is an isomorphism as $\text{Gal}(L/Q)$-modules

$$\mathbb{Q} \otimes \mathcal{O}_H^\chi \simeq \text{Ind}_{G_{\infty}}^{\text{Gal}(L/Q)} \mathbb{Q}.$$ 

It follows that there exists $u \in \mathcal{O}_L^\chi$ such that $\{\tau(u)u^{-1}\}_{\tau \in \Sigma_{L,1} \cup \Sigma_{L,2}}$ is a basis of $\mathcal{O}_L^\chi$. For $i = 1, 2$, put $u_i = \prod_{\sigma \in \Sigma_{L,i}} \sigma(u) \in \mathcal{O}_H^\chi$ and

$$u_i := e_i u_i = \sum_{\tau \in \text{Gal}(H/K)} \chi(\tau^{-1}) \otimes \tau(u_i)u_i^{-1} \in \mathcal{O}_H^\chi[\chi].$$

Then $\{u_1, u_2\}$ is a basis of $\mathcal{O}_H^\chi[\chi]$. Consider the matrix

$$M = \begin{pmatrix} \log_p(\sigma_1(u_1)) \log_p(\sigma_2(u_1)) \\ \log_p(\sigma_1(u_2)) \log_p(\sigma_2(u_2)) \end{pmatrix}.$$

Since $\chi \neq \chi^c$, we see that the row and the column vectors are also linearly independent over $\mathbb{Q}$ respectively by the Baker-Brumer theorem. According to Roy’s Six exponentials theorem, $M$ has rank 2. Therefore either $\begin{pmatrix} \log_p(\sigma_1(u_1)) \\ \log_p(\sigma_1(u_2)) \end{pmatrix}$ or $\begin{pmatrix} \log_p(\sigma_2(u_1)) \\ \log_p(\sigma_2(u_2)) \end{pmatrix}$ is invertible. This shows that either $\{\sigma_1, \sigma_2\}$ or $\{\sigma_1, \sigma_2c\}$ is a $p$-adic CM type that satisfies the $\Sigma$-Leopoldt conjecture for $\chi$. \hfill $\blacksquare$
