Abstract

The study of prevalence of malocclusion is one of the common problems of orthodontics. Study of the epidemiological data on the prevalence of malocclusion is an important determinant in planning appropriate levels of orthodontic services. The occurrence of occlusal anomalies varies between different countries, ethnic and age groups. Also, malocclusions have a multifactorial origin and can hardly ever be attributed to a single specific cause. Causes include general factors, such as genetic and hereditary components, nutritional deficiencies and abnormal pressure habits or local factors located directly in the dental arch such as supernumerary teeth, tooth decay and premature loss of primary teeth. In patients with occlusion anomalies is important aesthetic complaints, which causes to inferiority complex. Analysis of literature data confirms dental anomalies frequency around the world. Its frequency varies from 11% to 70%. The objective of this study was to determine the prevalence of malocclusion among school children of Georgia. The sample consisted of 500 children (316 females, 184 males) in the age group of 6-15 years.

Keywords: Malocclusion; Prevalence; Dental Anomalies

Introduction

Epidemiological data, the malocclusion has the third highest prevalence among oral pathologies, second only to caries and periodontal disease. It is therefore in the third position of the scale of priorities as to the dental problems of Global Public Health, according to WHO [1]. Age is the main determinant for progress of any disease. In context to the specialty of Pedodontics and Orthodontics, some developing malocclusions may get self-corrected with the progress of age. It is necessary to carry out epidemiologic studies of malocclusion in all regions at different age groups to grade the severity of malocclusion according to the respective age groups [2]. The causes that promote the evolution of this process are very diverse, which makes the malocclusion to be considered multifactorial, with hereditary, congenital, functional, environmental influences and nutritional, socioeconomic and educational factors [3]. The influences of harmful habits, among them, finger and pacifier sucking, are described in the literature [4] as a major etiologic factor of malocclusion in the phase of primary and mixed dentitions. Another factor worth mentioning is the presence and duration of breastfeeding. Children who are breast fed for at least 6 months, as recommended by WHO, tend to have lower prevalence of non-nutritive sucking habits, and if they are present, they will be shorter [5,6].

Malocclusions i.e. dental occlusion problems are the result of orofacial adaptability to various etiological factors which result in various implications ranging from aesthetic dissatisfaction to changes in speech, mastication, swallowing, temporomandibular joint dysfunction and orofacial pain [7]. The epidemiological situation of the population is important for planning and implementation of preventive dental services and treatment [8]. Regarding the epidemiological data, the latest survey on Oral Health, known as SB Brazil 2003, had their data published by the Ministry of Health. Oral health planners in any country are often called upon to estimate the orthodontic problems and treatment need in their communities by measuring certain occlusal features that if untreated may lead to functional impairment [9] and aesthetic dissatisfaction [10]. As socioeconomic factors interfere significantly with oral health, developing nations still have problems with children suffering from early tooth loss mostly due to caries [11,12].

Angle (1899) classified the malocclusion according to the relative position of the mandibular first permanent molar into class I at which the molar relationship is normal (buccal groove of the mandibular first molar is in line with the mesiobuccal cusp of the maxillary first molar but there is/are abnormalities within the arch like crowding, spacing etc.) and class II or distocclusion where the lower first molar is posteriorly positioned relative to upper molars. Class II can be further subdivided into division I where the upper incisors are proclined and division II where the upper central incisors are retroinclined and lateral incisors are overlapping.
the centrals. Class III is the third classification and characterized by more anterior position of the lower molars relative to upper molars [11].

**Material and Methods**

The study was conducted based on the search of review articles deposited in international scientific databases (Scopus, Thomson Reuters, Google Scholar, Pubmed). The search strategy was elaborated taking into consideration the index of citation of concrete articles. Screening and selection of articles was performed according to actuality of topic and incidence of diseases. The sample consisted of 500 children (316 females, 184 males) in the age group of 6-15 years randomly selected in “Orthodontic Center” in Georgia.

**Results**

| Anomalies                     | N    | %   |
|-------------------------------|------|-----|
| Normal occlusion              | 154  | 30.7|
| Malocclusion                  | 346  | 69.3|
| Crowding (lack of space in dental arch) | 128  | 24.7|
| Spacing of Teeth              | 90   | 17.9|
| Other anomalies               | 500  | 26.7|
| **Total**                     | 500  |     |

Table 1 shows the malocclusion of the subjects. Normal occlusions were found in 30.7% of subjects and 69.3% had malocclusions. Malocclusion is more often than other anomalies of teeth. It was especially high in the Crowding of teeth (24.7%) (Figure 1). Crowding of teeth is often found in the upper jaw teeth groups. The reason may be the undevelopment of the jaw bone, hyperdontia, macrodontia, Congenital anomalies, harmful habits. Crowding of teeth causes many problems (Breathing, chewing). Also was high anomalies of Spacing of Teeth (17.9%) (Figure 2). This anomaly can be found in the front part of the upper jaw. The causative factors are: Incompatibility of tooth size and jaw size, incorrect location of teeth, bad habits, congenital anomalies. Anomalies were recorded in equal numbers between boys and girls. In some cases, a few anomalies have been observed (Figures 3 & 4). As the picture shows, a 12-year-old girl has multiple dental anomalies.

**Discussion**

The results showed that 69.3% of the children from 6 to 15 had malocclusion. Different ethnic groups have variable occlusal traits; it is not only prevalence and severity of malocclusion that fluctuates, but also the awareness, need for treatment and demand differ according to socioeconomic and cultural status of the population. In England, the orthodontic treatment need 34.8% children from 6 to 18 years of age. In Turkey have been reported Orthodontic problems 37.77% in 6-10-years-old primary school children with a high socio-economic standard [12]. The study was conducted in India and in this study, it was observed a prevalence of 36.46% of malocclusion in population, classified as mild, moderate and severe. At the age of five, mild malocclusion was the most
frequent (22.1%), followed by moderate or severe (14.5%). In children aged 12, it was found 21% of very severe problems, which demonstrates that malocclusion may worsen with age, highlighting the importance of early treatment [9].

The highest scores of dental anomalies were seen among patients with Class II and Class III malocclusion. Most common occurring anomaly was rotation of teeth (18.80%), followed by hypodontia (10.90%) and most of the anomalies were observed in the mandibular arch. Hence, orthodontists should take this into consideration while planning treatment to reduce complications [13,14]. The reported prevalence of malocclusions is over 60% in preschool children and between 43 and 78% in schoolchildren14. In older children and adolescents, crowded teeth due to space deficiency in the dental arches are frequent [15,16]. The normal occlusion score in Jequié was similar to that in Swedish (26.4%) [17] and English children (26.8%) [18]. In African-American children, it has been reported that 17% of the children had normal occlusion, while another study found prevalence of 16.6% in white American children. Other occlusal problems, anterior crossbite was found 5.7% and open bite 13% [19]. In Class I and Class III individuals, malocclusion prevalence dropped from 47.6 to 36.2% and from 8.2 to 3.7% [20]. The Latino population may be the largest minority group in the United States by the year 2004. This study analyzes the occlusion of 507 Latino adolescents between the ages of 12 and 18 years. More than 93% of the subjects demonstrated some form of malocclusion [21,22].

Conclusion

As the study showed, in Georgia was observed high incidence of dental anomalies stand and malocclusion. The study revealed that they causes many social and functional problems. The results also showed that the reasons of malocclusion is bad habits and congenital anomalies. Exact and fast treatment is very important for future results.
