THE SIMPLEST MIXED FINITE ELEMENT METHOD FOR LINEAR ELASTICITY
IN THE SYMMETRIC FORMULATION ON n-RECTANGULAR GRIDS

JUN HU, HONGYING MAN, AND SHANGYOU ZHANG

Abstract. A family of mixed finite elements is proposed for solving the first order system of linear elasticity equations in any space dimension, where the stress field is approximated by symmetric finite element tensors. This family of elements has a perfect matching between the stress components and the displacement. The discrete spaces for the normal stress $\sigma_{ii}$, the shear stress $\sigma_{ij}$ and the displacement $u_i$ are span{1, $x_i$}, span{1, $x_i$, $x_j$} and span{1}, respectively, on rectangular grids. In particular, the definition remains the same for all space dimensions. As a result of these choices, the theoretical analysis is independent of the spatial dimension as well. In 1D, this element is nothing else but the 1D Raviart-Thomas element, which is the only conforming element in this family. In 2D and higher dimensions, they are new elements but of the minimal degrees of freedom. The total degrees of freedom per element is 2 plus 1 in 1D, 7 plus 2 in 2D, and 15 plus 3 in 3D. The previous record of the least degrees of freedom is, 13 plus 4 in 2D, and 54 plus 12 in 3D, on the rectangular grid. These elements are the simplest element for any space dimension.

The well-posedness condition and the optimal a priori error estimate of the family of finite elements are proved for both pure displacement and traction problems. Numerical tests in 2D and 3D are presented to show a superiority of the new element over others, as a superconvergence is surprisingly exhibited.

Keywords. First order system, symmetric stress field, mixed finite element, nonconforming finite element, inf-sup condition.

1. Introduction

The first order system of equations, for the symmetric stress field $\sigma \in \Sigma := H(\text{div}, \Omega, \mathbb{S})$ and the displacement field $u \in V := L^2(\Omega, \mathbb{R}^n)$, reads: Find $(\sigma, u) \in \Sigma \times V$ such that

\[
(A\sigma, \tau) + (\text{div} \tau, u) = 0 \quad \forall \tau \in \Sigma,
\]

\[
(\text{div} \sigma, v) = (f, v) \quad \forall v \in V.
\]

Here the symmetric tensor-valued stress space $\Sigma$ and the vector-valued displacement space $V$ are, respectively,

\[
H(\text{div}, \Omega, \mathbb{S}) = \left\{ (\sigma_{ij})_{n \times n} \in H(\text{div}, \Omega) \mid \sigma_{ij} = \sigma_{ji} \right\},
\]

\[
L^2(\Omega, \mathbb{R}^n) = \left\{ (u_1, \ldots, u_n)^T \mid u_i \in L^2(\Omega) \right\}.
\]

In 1D, one example of the problem (1.1) is the mixed formulation of the 1D Poisson equation; In 2D and 3D, the stress-displacement formulation based on the Hellinger-Reissner principle for the linear elasticity can be regarded as a celebrated example of (1.1).

Because of the symmetry constraint on the stress tensor, $\sigma_{ij} = \sigma_{ji}$, it is extremely difficult to construct stable conforming finite elements of (1.1) even if for 2D and 3D, as stated in the plenary presentation to the 2002 International Congress of Mathematicians by D. N. Arnold. Hence compromised works use composite elements [6, 22], or enforce the symmetry condition weakly [2, 5, 11, 24, 27, 28, 29]. The landmarks in this direction are the respective works of Arnold and Winther [8] and Arnold, Awanou, and...
In this paper, a new family of minimal, any space-dimensional, symmetric, nonconforming mixed finite elements for the problem (1.1) is constructed. It is motivated by a simple fact that, by (1.2), the derivative on a normal stress component $\sigma_{ii}$ is only in $x_i$ direction; while those on $\sigma_{ij}$ are only in $x_i$ and $x_j$ directions. Thus, the minimal finite element space for $\sigma_{ii}$ would be $\text{span}\{1, x_i\}$ on each $n$-dimensional rectangular element; the minimal finite element space for $\sigma_{ij}$ would be $\text{span}\{1, x_i, x_j\}$ on each $n$-dimensional rectangular element. For the displacement (1.3), there is no derivative and the minimal finite element space would be the constant space $\text{span}\{1\}$. The spaces are displayed in the right diagram in Figure 1 and in Figure 2. Surprisingly, it is shown that these minimal finite element spaces can actually form a family of stable and convergent methods for (1.1). However, the analysis herein has to overcome the difficulty to prove the discrete inf-sup condition, one key ingredient for the stability analysis of the mixed finite element method [12], and the difficulty related to nonconformity of the discrete spaces for the stresses. For both the elasticity problem and the Poisson problem, the stability analysis of mixed finite element methods in literature is established by special commuting properties of canonical interpolation operators defined by degrees of freedom of discrete stress spaces, see, for instance, [1, 3, 4, 8] and [12]. To overcome the first difficulty, a new macro-element technique is proposed to prove a Fortin Lemma for mixed methods under consideration. Note that the macro-element technique is widely used to analyze the stability of mixed methods for the Stokes problem, see [12] and references therein. However, it is not used to the elasticity problem before. For the pure displacement
problem, an explicit constructive proof is also given for the discrete inf-sup condition. In order to deal with the second difficulty, a superconvergence property of the consistency error is proved. The mathematical elegance and beauty of this family of minimal elements is gestated within, besides the perfect matching, the independence of the spatial dimension \( n \). In \( n \) dimension, the constructive proof of the discrete inf-sup condition can be divided into \( n \) steps of that for the 1D Raviart-Thomas element, and the consistency error can be decomposed as \( n \) two-dimensional consistency errors (For 1D, there is no consistency error.)

The superiority of the family of elements over the existing elements in the literature is its simplicity and high accuracy. In fact, a family of 2D rectangular, conforming elements, of which the lowest order has 45 stress and 12 displacement degrees of freedom per element, is proposed in \([3]\). A nonconforming mixed finite element based on rectangular grids is proposed with 19 stress and 6 displacement degrees of freedom on each element in \([30]\). Later on, a simplified mixed finite element on 2D rectangular grids is constructed with 13 stress and 4 displacement degrees of freedom on each rectangle independently in \([21, 31]\), see the left diagram in Figure 1 which is the simplest rectangular element of first order in 2D in the literature so far. Doubtless, the 2D element with 7 stress and 2 displacement degrees of freedom on each rectangle of this paper is the simplest rectangular element, see the right diagram in Figure 1. Due to a perfect matching (for symmetry constraint), the new element has much less degrees of freedom (dof) but a higher order of approximation property, compared to previous elements \([21, 30, 31]\). This is confirmed by numerical results. In 3D, the new element has only 15 stress plus 3 displacement dof on each element, much simpler than the first order element, with 54 plus 12 dof per element, of \([23]\). Notice that the element of \([23]\) is previously the simplest rectangular element in 3D.

The rest of the paper is organized as follows. The minimal element in 2D is introduced in Section 2. The well-posedness of the finite element problem, i.e. the discrete coerciveness and the discrete inf-sup condition, is proved in Section 3 for the pure displacement problem. The optimal order convergence is shown in Section 4. The element is extended to any space-dimension in Section 5. In Section 6, the stability of the minimal element is shown for the pure traction problem. Numerical results in 2D and 3D, including that for a pure traction problem, are provided in Section 7, which show a superconvergence of the minimal elements herein.

## 2. A minimal element in 2D

The 2D element is presented separately in this section for fixing the main idea while the whole family will be developed in Section 5. Also for simplicity we consider a pure displacement problem first. The analysis for other boundary value problems will be given in Section 6.

Consider a pure displacement problem (and a pure traction problem in Section 6):

\[
\begin{align*}
\text{(2.1a)} & \quad \text{div}(A^{-1}\epsilon(u)) = f \quad \text{in} \quad \Omega, \\
\text{(2.1b)} & \quad u = 0 \quad \text{on} \quad \Gamma = \partial \Omega,
\end{align*}
\]

The domain is assumed to be a rectangle (it is straightforward that results can be extended to domains which can be covered by rectangles), which is subdivided by a family of rectangular grids \( T_h \) (with grid size \( h \)).

The set of all edges in \( T_h \) is denoted by \( E_h \), which is divided into two sets, the set \( E_{h,H} \) of horizontal edges and the set \( E_{h,V} \) of vertical edges. Given any edge \( e \in E_h \), one fixed unit normal vector \( \mathbf{n} = (n_1, n_2) \) is assigned. For each \( K \in T_h \), define the affine invertible transformation

\[
F_K : \quad \hat{K} \to K, \quad \begin{pmatrix} \hat{x} \\ \hat{y} \end{pmatrix} \to \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \frac{h_{x,K}}{2} \hat{x} + x_0,K \\ \frac{h_{y,K}}{2} \hat{y} + y_0,K \end{pmatrix},
\]

with the center \((x_0,K, y_0,K)\) of \( K \), the horizontal length \( h_{x,K} \), and the vertical length \( h_{y,K} \), and the reference element \( \hat{K} = [-1, 1]^2 \).
On each element $K \in \mathcal{T}_h$, a constant finite element space for the displacement is defined by

$$V_K = \mathcal{P}_0(K, \mathbb{R}^2) = \left\{ \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} \mid v_1, v_2 \in \mathcal{P}_0(K) \right\};$$

while the symmetric linear finite element space for the stress is defined by

$$\Sigma_K = \left\{ \sigma = \begin{pmatrix} \mathcal{P}_{1,1}(K) \\ \mathcal{P}_{1}(K) \\ \mathcal{P}_{1,2}(K) \end{pmatrix} \mid \sigma \in \Sigma \right\},$$

where subscript $\Sigma$ indicates a symmetric matrix stress, and

$$\mathcal{P}_{1,1}(K) = \text{span}\{1, x\},$$

$$\mathcal{P}_1(K) = \text{span}\{1, x, y\},$$

$$\mathcal{P}_{1,2}(K) = \text{span}\{1, y\}.$$ 

The dimension of the space $V_K$ is 2, and that of $\Sigma_K$ is 7. The nodal degrees of freedom for $(v_1, v_2)$, $\sigma_{11}$, and $\sigma_{22}$, are

- the moment of degree 0 on $K$ for $v_1$ and $v_2$;
- the moments of degree 0 on two vertical edges of $K$ for $\sigma_{11}$;
- the moments of degree 0 on two horizontal edges of $K$ for $\sigma_{22}$;

The nodal degrees of freedom for $\sigma_{12}$ will be studied as follows. Locally $\mathcal{P}_1(K)$ is the space of linear polynomials. Globally, let $W_h$ be the $\mathcal{P}_1$-nonconforming space on $\mathcal{T}_h$, which is first introduced in [25] as a nonconforming approximation space to $H^1(\Omega)$ on the quadrilateral mesh; see also [20]. To be exact, $W_h$ is the space of piecewise linear polynomials, which are continuous at all mid-edge points of triangulation $\mathcal{T}_h$. $W_h$ is the finite element space approximating function $\sigma_{12}$.

The global spaces $\Sigma_h$ and $V_h$ are defined by

$$\Sigma_h = \left\{ \sigma = \begin{pmatrix} \sigma_{11} \\ \sigma_{12} \\ \sigma_{22} \end{pmatrix} \in L^2(\Omega, \mathbb{R}^2) \mid \sigma|_K \in \Sigma_K \text{ for all } K \in \mathcal{T}_h, \right\},$$

$$\sigma_{11} \text{ is continuous on all vertical interior edges,}$$

$$\sigma_{22} \text{ is continuous on all horizontal interior edges,}$$

$$\sigma_{12} \text{ is continuous at all mid-points of interior edges } \},$$

$$V_h = \{ v \in L^2(\Omega, \mathbb{R}^2) \mid v|_K \in V(K) \text{ for all } K \in \mathcal{T}_h \}. $$

Since $\sigma_{11}$ is continuous on all vertical interior edges, the derivative $\partial_x \sigma_{11}$ is well-defined in $L^2(\Omega)$. However, $\sigma_{12}$ is not continuous on $\Omega$ so that $\partial_x \sigma_{12}$ and $\partial_y \sigma_{12}$ are not in $L^2(\Omega)$. Therefore the discrete stress space $\Sigma_h$ is a nonconforming approximation to $H(\text{div}, \Omega, \mathbb{S})$. So the discrete divergence operator $\text{div}_h$ is defined elementwise with respect to $\mathcal{T}_h$,

$$\text{div}_h \tau|_K = \text{div}(\tau|_K) \quad \forall \tau \in \Sigma_h.$$ 

The mixed variational form for (2.1a) is (1.1). The mixed finite element approximation of Problem (1.1) reads: Find $(\sigma_h, u_h) \in \Sigma_h \times V_h$ such that

$$\begin{cases} (A\sigma_h, \tau) + (\text{div}_h \tau, u_h) = 0 & \forall \tau \in \Sigma_h, \\ (\text{div}_h \sigma_h, v) = (f, v) & \forall v \in V_h, \end{cases}$$

It follows from the definition of $\Sigma_K$ that $\text{div}_h \tau_h$ are piecewise constant for any $\tau_h \in \Sigma_h$, which leads to

$$\text{div}_h \Sigma_h \subset V_h.$$ 

This, in turn, leads to a strong discrete divergence-free space:

$$Z_h = \{ \tau_h \in \Sigma_h \mid (\text{div}_h \tau_h, v) = 0 \quad \forall v \in V_h \} = \{ \tau_h \in \Sigma_h \mid \text{div}_h \tau_h = 0 \text{ pointwise } \}. $$
For the analysis, define the following broken norm:

\[
\| \tau \|_{H(\text{div})_h} = (\| \tau \|_0^2 + \| \text{div}_h \tau \|_0^2)^{1/2} \quad \forall \tau \in \Sigma_h.
\]

The rest of this section is devoted to an alternative definition to $W_h$, the space for $\sigma_{12}$ in $\Sigma_h$. The dimension of the space $\mathcal{P}_1(K)$ is three, less than the number of edges or vertexes of element $K$. The discrete shear stress $\sigma_{12}$ is still defined by four vertex-value functionals, which are not linearly independent though. A constraint can be posed on those four functionals if one defines a functional set $N$ on $\mathcal{P}_1(K)$, cf. \[25\] Lemma 2.1.

Here the idea from \[20\] of a frame for $\mathcal{P}_1(K)$ will be used. To this end, define the frame for the space $\mathcal{P}_1(K) = \text{span}\{1, \hat{x}, \hat{y}\}$ by

\[
\phi_{-1,-1} = \frac{1 - \hat{x} - \hat{y}}{4}, \quad \phi_{1,-1} = \frac{1 + \hat{x} - \hat{y}}{4}, \quad \phi_{1,1} = \frac{1 + \hat{x} + \hat{y}}{4}, \quad \phi_{-1,1} = \frac{1 - \hat{x} + \hat{y}}{4}.
\]

This frame is depicted in Figure 3.

\[\text{Figure 3. Four nodal (frame/not basis) functions of } W_h \text{ on } \hat{K}.\]

An interpolation operator $\Pi_{12}$, from $H^2(\Omega)$ (i.e., some continuous functions) to $W_h$ is needed. The interpolation on $\hat{K}$ is defined as

\[
\hat{\Pi}_{12}\hat{\sigma}_{12} = \hat{\sigma}_{12}(\hat{x}_{1,\hat{K}}, \hat{y}_{1,\hat{K}})\phi_{-1,-1} + \hat{\sigma}_{12}(\hat{x}_{2,\hat{K}}, \hat{y}_{2,\hat{K}})\phi_{1,-1} + \hat{\sigma}_{12}(\hat{x}_{3,\hat{K}}, \hat{y}_{3,\hat{K}})\phi_{1,1} + \hat{\sigma}_{12}(\hat{x}_{4,\hat{K}}, \hat{y}_{4,\hat{K}})\phi_{-1,1},
\]

where the four vertexes are numbered counterclockwise,

\[
(\hat{x}_{1,\hat{K}}, \hat{y}_{1,\hat{K}}) = (-1, -1),
(\hat{x}_{2,\hat{K}}, \hat{y}_{2,\hat{K}}) = (1, -1),
(\hat{x}_{3,\hat{K}}, \hat{y}_{3,\hat{K}}) = (1, 1),
(\hat{x}_{4,\hat{K}}, \hat{y}_{4,\hat{K}}) = (-1, 1).
\]

In the same fashion, the interpolation $\Pi_{12}$ is defined on all $K \in T_h$ by

\[
\Pi_{12}\sigma_{12}(x, y) = \sigma_{12}(x_{1,K}, y_{1,K})\phi_{-1,-1}(F_K^{-1}(x, y)) + \sigma_{12}(x_{2,K}, y_{2,K})\phi_{1,-1}(F_K^{-1}(x, y)) + \sigma_{12}(x_{3,K}, y_{3,K})\phi_{1,1}(F_K^{-1}(x, y)) + \sigma_{12}(x_{4,K}, y_{4,K})\phi_{-1,1}(F_K^{-1}(x, y)),
\]

where $(x, y) \in K$, and $(x_{i,K}, y_{i,K})$ are the four vertexes of $K$. As $\phi_{-1,-1}(0, -1) = \phi_{1,-1}(0, -1) = 1/2$, it follows that

\[
\Pi_{12}\sigma_{12} |_{e_1}(e_m) = \frac{1}{2}(\sigma_{12}(e_1) + \sigma_{12}(e_2)),
\]
where $e_+$ and $e_-$ are two sides of an edge $e \in E_h$, $e_m$ is the mid-point of $e$, and $e_1$ and $e_2$ are two endpoints of $e$. That is, $\Pi_{12} \sigma_{12}$ is continuous at all mid-points of edges. For a vertex $v_0$ in $\mathcal{T}_h$,

$$c_{i,j} = (ih, jh), \quad 0 \leq i, j \leq N, \quad N = 1/h,$$

it may be shared by one, or two, or four elements $K \in \mathcal{T}_h$. The combination of the frame functions at the vertex $c_{i,j}$ forms one global frame function $\phi_{i,j}$. For example, at vertex $c_{0,1}$, as it is shared by two elements, $K_{1,1} = [0, h] \times [0, h]$ and $K_{1,2} = [0, h] \times [h, 2h]$,

$$\psi_{0,1} = \begin{cases} \phi_{-1,1}(\frac{x}{h} - \frac{1}{2}), \frac{y}{h} - \frac{1}{2}) & (x, y) \in K_{1,1}, \\ \phi_{-1,-1}(\frac{x}{h} - \frac{1}{2}), \frac{y}{h} - \frac{1}{2}) & (x, y) \in K_{1,2}, \\ 0 & \text{elsewhere on } \Omega. \end{cases}$$

Note that $\psi_{i,j}$ is not continuous at $c_{i,j}$. Thus, the finite element space for $\sigma_{12}$ in (2.4) is

$$W_h = \{ s \in L^2(\Omega) \mid s = \sum_{i,j=0}^{N} p_{ij} \psi_{i,j} \}.$$ 

3. Well-posedness of the discrete problem in 2D

This section considers the well-posedness of the discrete problem (2.6), which needs the following two conditions.

(1) K-ellipticity. There exists a constant $C > 0$, independent of the meshsize $h$ such that

$$\langle A\tau, \tau \rangle \geq C \|	au\|_{H^1(\Omega)}^2 \quad \forall \tau \in Z_h,$$

where $Z_h$ is the divergence-free space defined in (2.7).

(2) Discrete B-B condition. There exists a positive constant $C > 0$ independent of the meshsize $h$, such that

$$\inf_{v \in V_h} \sup_{\tau \in Z_h} \frac{\langle \nabla_h \tau, v \rangle}{\|	au\|_{H^1(\Omega)}\|v\|_0} \geq C.$$ 

**Theorem 3.1.** For the discrete problem (2.6), the K-ellipticity (3.1) and the discrete B-B condition (3.2) hold uniformly. Consequently, the discrete mixed problem (2.6) has a unique solution $(\sigma_h, \psi_h) \in \Sigma_h \times V_h$.

**Proof.** It follows from (2.7) that for all $\tau \in Z_h$, $\nabla_h \tau = 0$. Thus $\|
abla_h \tau\|_0 = 0$ and $\|
abla_h \tau\|_{H^1(\Omega)} = 0$. Since the operator $A$ is symmetric and positive definite, the $K$-ellipticity of the bilinear form $\langle A\tau, \tau \rangle$ follows.

It remains to show the discrete B-B condition (3.2). Since the usual technique based on canonical interpolations operators for discrete stress spaces [4, 8] is inapplicable here, a constructive proof is adopted. For convenience, suppose that the domain $\Omega$ is a unit square $[0,1]^2$ which is triangulated evenly into $N^2$ elements, $\{K_{ij}\}$. For any $v \in V_h$, it can be decomposed as a sum,

$$v_h = \sum_{i=1}^{N} \sum_{j=1}^{N} V_{ij} \varphi_{ij}(x, y),$$

where $\varphi_{ij}(x)$ is the characteristic function on the element $K_{ij}$, and $V_{ij} = (V_{1,ij}, V_{2,ij}) = (v_h|_{K_{ij}})$. A discrete stress function $\tau_h \in \Sigma_h$ will be constructed with

$$\nabla_h \tau_h = v_h \text{ and } \|	au_h\|_{H^1(\Omega)} \leq C\|v_h\|_0.$$ 

The construction of $\tau_h$ is motivated by a simple proof of the inf-sup condition of the 1D Raviart-Thomas element for the 1D Poisson problem. The shear stress $\tau_{12}$ can be taken zero, i.e., $\tau_{12} \equiv 0$; the normal stress $\tau_{11}$ (resp. $\tau_{22}$) of $\tau_h$ can be constructed so that it is independent of the second (resp. first) component of
\( v_h \). In addition, \( \tau_{11} \) (resp. \( \tau_{22} \)) can be a continuous piecewise linear function of the variable \( x \) (resp. \( y \)) and a piecewise constant function of \( y \) (resp. \( x \)). Therefore, they are of form

\[
\tau_{11}(x, y) = h \sum_{m=1}^{i-1} V_{1,mj} + V_{1,ij}(x - x_{i-1}),
\]

\[
\tau_{22}(x, y) = h \sum_{k=1}^{j-1} V_{2,ik} + V_{2,ij}(y - y_{j-1}),
\]

for \( x_{i-1} \leq x < x_i \) and \( y_{j-1} \leq y < y_j \) ((\( x_i, y_j \)) is the upper-right corner vertex of square \( K_{ij} \)). Thus, define

\[
\tau_h = \begin{pmatrix} \tau_{11} \\ 0 \\ \tau_{22} \end{pmatrix} \in \Sigma_h.
\]

By this construction, \( \partial_x \tau_{11} = (v_h)_1 \) and \( \partial_y \tau_{22} = (v_h)_2 \). This gives

\[
\text{div}_h \tau_h = v_h.
\]

An elementary calculation gives

\[
\| v_h \|_0^2 = \sum_{i,j=1}^{N} \| V_{ij} \varphi_{ij} \|_{0,K_{ij}}^2 = \sum_{i,j=1}^{N} \int_{K_{ij}} |V_{ij} \varphi_{ij}|^2 \, dx \, dy
\]

\[
= \sum_{i,j=1}^{N} (|V_{1,ij}|^2 + |V_{2,ij}|^2) h^2.
\]

By the Schwarz inequality,

\[
\| \tau_{11} \|_0^2 = \sum_{i,j=1}^{N} \int_{K_{ij}} \left( \sum_{m=1}^{i-1} V_{1,mj} + V_{1,ij}(x - x_{i-1}) \right)^2 \, dx \, dy
\]

\[
\leq \sum_{i,j=1}^{N} \int_{K_{ij}} \left( h^2 \sum_{m=1}^{i-1} (V_{1,mj})^2 + (V_{1,ij})(x - x_{i-1})^2 \right) \cdot i \, dx \, dy.
\]

Further, since \( N = 1/h \) and \( \int_{K_{ij}} = h^2 \),

\[
\| \tau_{11} \|_0^2 \leq \sum_{i,j=1}^{N} \left( h^2 \sum_{m=1}^{i} (V_{1,mj})^2 \right) \cdot N h^2 \leq \sum_{j=1}^{N} \left( h^2 \sum_{m=1}^{N} (V_{1,mj})^2 \right) \cdot N^2 h^2
\]

\[
= h^2 \sum_{i,j=1}^{N} (V_{1,ij})^2.
\]

A similar argument leads to

\[
\| \tau_{22} \|_0^2 \leq h^2 \sum_{i,j=1}^{N} (V_{2,ij})^2.
\]

The combination of the aforementioned two identities and two inequalities yields

\[
\| \tau_h \|_{H(\text{div}_h)}^2 = \| \tau_h \|_0^2 + \| \text{div}_h \tau_h \|_0^2
\]

\[
= \| \tau_{11} \|_0^2 + \| \tau_{22} \|_0^2 + \| v_h \|_0^2 \leq 2 \| v_h \|_0^2.
\]

Hence, for any \( v_h \in V_h \), the B-B condition (3.2) holds with \( C = 1/\sqrt{2} \):

\[
\inf_{v_h \in V_h} \sup_{\tau \in \Sigma_h} \frac{(\text{div}_h \tau, v_h)}{\| \tau \|_{H(\text{div}_h)} \| v_h \|_0} \geq \inf_{v_h \in V_h} \frac{\| v_h \|_0^2}{\sqrt{2} \| v_h \|_0^2} = \frac{1}{\sqrt{2}}.
\]

This completes the proof.
The section is devoted to the error estimate stated in Theorem 4.1, which is based on the approximation error estimate of Theorem 4.2 and the consistency error estimate of Theorem 4.3.

In order to analyze the approximation error, for any $\tau \in H(\text{div}, \Omega, S) \cap H^2(\Omega, S)$, define an interpolation

\begin{equation}
\Pi_h \sigma = \begin{pmatrix} \Pi_{11} \sigma_{11} \\ \Pi_{12} \sigma_{12} \\ \Pi_{22} \sigma_{22} \end{pmatrix} \in \Sigma_h,
\end{equation}

where $\Pi_{11}$ and $\Pi_{22}$ are standard, satisfying, respectively,

\begin{align}
\int_e \Pi_{11} \sigma_{11} ds &= \int_e \sigma_{11} ds \text{ for any vertical edge } e \in \mathcal{E}_h, \\
\int_e \Pi_{22} \sigma_{22} ds &= \int_e \sigma_{22} ds \text{ for any horizontal edge } e \in \mathcal{E}_h.
\end{align}

$\Pi_{12}$ is the interpolation operator defined in (2.9), from the space $H^2(\Omega)$ to $W_h$. It is shown by Park and Sheen [25] that

\begin{equation}
|v - \Pi_{12} v|_{m,K} \leq Ch^{2-m} |v|_{2,K}, \ m = 0, 1, \ K \in \mathcal{T}_h.
\end{equation}

**Theorem 4.1.** For any $\sigma \in H^2(\Omega, S)$, it holds that

\begin{align}
\|\sigma - \Pi_h \sigma\|_0 &\leq Ch\|\sigma\|_1, \\
\|\text{div}_h (\sigma - \Pi_h \sigma)\|_0 &\leq Ch\|\sigma\|_2.
\end{align}

**Proof.** By the scaling argument and the standard approximation theory, the following two estimates will be proved

\begin{align}
|\sigma_{11} - \Pi_{11} \sigma_{11}|_{0,K} &\leq Ch|\sigma_{11}|_{1,K} \ \forall K \in \mathcal{T}_h, \\
|\partial_x (\sigma_{11} - \Pi_{11} \sigma_{11})|_{0,K} &\leq Ch|\partial_x \sigma_{11}|_{1,K} \ \forall K \in \mathcal{T}_h.
\end{align}

For any element $K \in \mathcal{T}_h$, by (4.2) (i.e., the interpolation (4.2) is equivalent to a mid-point interpolation),

\begin{align}
|\sigma_{11} - \Pi_{11} \sigma_{11}|^2_{0,K} &= \frac{h_x h_y}{4} \int_K |\hat{\sigma}_{11} - \hat{\Pi}_{11} \hat{\sigma}_{11}|^2 \hat{d}x \hat{d}y \\
&\leq Ch^2 |\sigma_{11}|^2_{1,K} \leq Ch^2 |\sigma_{11}|^2_{1,K}.
\end{align}

This is (4.5). By the reference mapping,

\begin{align}
\left\|\frac{\partial}{\partial x} (\sigma_{11} - \Pi_{11} \sigma_{11})\right\|^2_{0,K} &= \frac{h_y}{h_x} \int_K \left\|\frac{\partial}{\partial x} (\hat{\sigma}_{11} - \hat{\Pi}_{11} \hat{\sigma}_{11})\right\|^2 \hat{d}x \hat{d}y \\
&\leq C \int_K \left\|\frac{\partial}{\partial x} \hat{\sigma}_{11} - \frac{\partial}{\partial x} \hat{\Pi}_{11} \hat{\sigma}_{11}\right\|^2 \hat{d}x \hat{d}y.
\end{align}

Now

\begin{align}
\int_K \frac{\partial}{\partial x} \Pi_{11} \hat{\sigma}_{11} d\hat{x} d\hat{y} &= \int_{-1}^1 \{((\Pi_{11} \hat{\sigma}_{11}) (1, \hat{y}) - (\Pi_{11} \hat{\sigma}_{11}) (-1, \hat{y})) d\hat{y} \\
&= \int_{-1}^1 \{\hat{\sigma}_{11} (1, \hat{y}) - \hat{\sigma}_{11} (-1, \hat{y})\} d\hat{y} \\
&= \int_{-1}^1 \frac{\partial}{\partial x} \hat{\sigma}_{11} d\hat{d}y,
\end{align}
This means \( \frac{\partial}{\partial x}(\Pi_{11}\hat{\sigma}_{11}) = P_{0,K}(\frac{\partial \hat{\sigma}_{11}}{\partial x}) \), where \( P_{0,K} \) is the projection operator onto the constant space on element \( K \). A substitution of it into (4.7) leads to

\[
\left\| \frac{\partial}{\partial x}(\sigma_{11} - \Pi_{11}\sigma_{11}) \right\|_{0,K}^2 \leq C \left\| \frac{\partial \sigma_{11}}{\partial x} - P_{0,K}(\frac{\partial \hat{\sigma}_{11}}{\partial x}) \right\|_{0,K}^2 \leq C \inf_{c \in \mathbb{R}} \left( \left\| \frac{\partial \sigma_{11}}{\partial x} - c \right\|_{0,K}^2 \right).
\]

By the Bramble-Hilbert Lemma,

\[
\left\| \frac{\partial}{\partial x}(\sigma_{11} - \Pi_{11}\sigma_{11}) \right\|_{0,K}^2 \leq C \left\| \frac{\partial \sigma_{11}}{\partial x} \right\|_{1,K}^2 \leq Ch^2 \left\| \frac{\partial \sigma_{11}}{\partial x} \right\|_{1,K}.
\]

This is (4.6).

A similar argument yields

\[
\|\sigma_{22} - \Pi_{22}\sigma_{22}\|_{0,K} \leq Ch|\sigma_{22}|_{1,K} \quad \forall K \in \mathcal{T}_h,
\]

(4.8)

\[
\left\| \frac{\partial}{\partial y}(\sigma_{22} - \Pi_{22}\sigma_{22}) \right\|_{0,K} \leq Ch \left\| \frac{\partial \sigma_{22}}{\partial y} \right\|_{1,K} \quad \forall K \in \mathcal{T}_h.
\]

(4.9)

Noting that the \( L^2 \) norm on \( \Sigma \) is

\[
\|\sigma\|_{0,K}^2 = \|\sigma_{11}\|_{0,K}^2 + 2\|\sigma_{12}\|_{0,K}^2 + \|\sigma_{22}\|_{0,K}^2,
\]

A combination of the estimates (4.5), (4.6), (4.8), (4.9) and (4.4), completes the proof.

**Theorem 4.2.** Assume that \((\sigma, u)\) be the solution to the problem (1.1) with \( u \in H^1_0(\Omega, \mathbb{R}^2) \cap H^2(\Omega, \mathbb{R}^2) \).

Then,

\[
\sup_{\tau_h \in \Sigma_h} \left( A\sigma, \tau_h \right) + \left( \text{div} h\tau_h, u \right) \leq Ch|u|_2.
\]

(4.10)

**Proof.** It follows from the first equation of (1.1) that \( A\sigma = \frac{1}{2}(\nabla u + \nabla u^T) \) for the exact solution \( u \in H^1_0(\Omega, \mathbb{R}^2) \). An elementwise integration by parts gives

\[
(\epsilon(u), \tau_h) = -(\text{div} h\tau_h, u) + \sum_{K \in \mathcal{T}_h} \int_{\partial K} \tau_h n \cdot uds \quad \forall \tau_h \in \Sigma_h,
\]

which implies

\[
(A\sigma, \tau_h) + (\text{div} h\tau_h, u) = \sum_{K \in \mathcal{T}_h} \int_{\partial K} \tau_h n \cdot uds.
\]

(4.11)

**Figure 4.** \( \tau_h \cdot n \) on the four edges of element \( K \), cf. (4.12).
Let $\tau_h|_K = \begin{pmatrix} \tau_{11} \\ \tau_{21} \\ \tau_{22} \end{pmatrix}$, cf. Figure 1. Since $\tau_{11}$ is continuous in the $x$-direction and $\tau_{22}$ is continuous in the $y$-direction, there is a cancellation for these two components on the inter-element boundary. Since $u \in H^2(\Omega, \mathbb{R}^2) \cap H_0^1(\Omega, \mathbb{R}^2)$,

\begin{equation}
\sum_{K \in T_h} \int_{\partial K} \tau_h \cdot nuds \\
= \sum_{K \in T_h} \left[ (\int_{e_{2,K}} - \int_{e_{4,K}}) \tau_{12}u_2ds + (\int_{e_{1,K}} - \int_{e_{3,K}}) \tau_{12}u_1ds \right].
\end{equation}

For any $v \in H^1(K)$, define the $L^2$-projection operator $J_e$ on an edge $e$ by

$$J_e v = \frac{1}{|e|} \int_e v ds.$$ 

Because $\tau_{12}$ is continuous at the mid-point of all edges, it follows that, including boundary edges where $u_i = 0$, on the horizontal edges $\partial_{h,H}$,

$$\sum_{K \in T_h} \left[ (\int_{e_{1,K}} - \int_{e_{3,K}}) \tau_{12}u_1ds = \sum_{e \in \partial_{h,H}} \int_e (\tau_{12}|_{e_+} - \tau_{12}|_{e_-})u_1ds \right]$$

$$= \sum_{e \in \partial_{h,H}} \int_e (\tau_{12}|_{e_+} - \tau_{12}|_{e_-})(u_1 - J_e u_1)ds.$$ 

After inserting a same constant $J_K \tau_{12} = \int_K \tau_{12} dx dy / |K|$ into the two integrals on two horizontal edges of one element $K$, the sum can be rewritten as

\begin{equation}
\sum_{K \in T_h} \left[ (\int_{e_{1,K}} - \int_{e_{3,K}}) \tau_{12}u_1ds \\
= \sum_{K \in T_h} \int_{e_{1,K}} \tau_{12}(u_1 - J_{e_{1,K}} u_1)ds - \int_{e_{3,K}} \tau_{12}(u_1 - J_{e_{3,K}} u_1)ds \\
= \sum_{K \in T_h} \int_{e_{1,K}} (\tau_{12} - J_K \tau_{12})(u_1 - J_{e_{1,K}} u_1)ds \\
- \int_{e_{3,K}} (\tau_{12} - J_K \tau_{12})(u_1 - J_{e_{3,K}} u_1)ds.
\end{equation}

There is some superconvergence property for the two terms in (4.13) if they are considered together. In fact, on the reference element $K$, $\tilde{\tau}_{12}(\hat{x}, \pm 1) = \tilde{\tau}_{12}(0,0) + \hat{x} \partial_x \tilde{\tau}_{12}(0,0) \pm \partial_y \tilde{\tau}_{12}(0,0)$, and $J_K \tilde{\tau}_{12} = \tilde{\tau}_{12}(0,0)$. The property of $J_e$ gives

$$\frac{1}{2} \int_{-1}^1 (\hat{x} - J_K \hat{x}) \left[ (\hat{u}_1 - J_{e_{i_1}} \hat{u}_1)(\hat{x}, -1) - (\hat{u}_1 - J_{e_{i_3}} \hat{u}_1)(\hat{x}, 1) \right] d\hat{x}$$

$$= -\frac{1}{2} \int_{-1}^1 \hat{x} \frac{\partial}{\partial \hat{x}} \hat{\tau}_{12} \left[ \int_{-1}^1 \frac{\partial}{\partial \hat{y}} \hat{u}_1 d\hat{y} - \frac{1}{2} \int_{-1}^1 (\hat{u}(\hat{x}, 1) - \hat{u}(\hat{x}, -1)) d\hat{x} \right] d\hat{x}$$

$$= -\frac{1}{2} \int_{-1}^1 \hat{x} \frac{\partial}{\partial \hat{x}} \hat{\tau}_{12} \left[ \int_{-1}^1 \frac{\partial}{\partial \hat{y}} \hat{u}_1 d\hat{y} - \frac{1}{2} \int_{-1}^1 (\frac{\partial}{\partial \hat{y}} \hat{u}(\hat{t}, \hat{y})) d\hat{y} d\hat{t} \right] d\hat{x}$$

$$= -\frac{1}{4} \int_{-1}^1 \hat{x} \frac{\partial}{\partial \hat{x}} \hat{\tau}_{12} \left[ \int_{-1}^1 \frac{\partial}{\partial \hat{y}} \hat{u}_1(\hat{t}, \hat{y}) d\hat{y} d\hat{t} \right] d\hat{x}$$

$$= -\frac{1}{4} \int_{-1}^1 \hat{x} \frac{\partial}{\partial \hat{x}} \hat{\tau}_{12} \left[ \int_{-1}^1 \int_{\hat{t}}^{\hat{x}} \frac{\partial^2}{\partial \hat{x} \partial \hat{y}} \hat{u}_1(\hat{s}, \hat{y}) d\hat{y} d\hat{t} \right] d\hat{x}.$$
By the Schwarz inequality and (4.13),
\[
\left| \sum_{K \in T_h} \left( \int_{e_{1,K}} - \int_{e_{3,K}} \right) \tau_{12} u_1 ds \right|^2 = \frac{h^2}{2^2} \sum_{K \in T_h} \int_{-1}^{1} \int_{-1}^{1} \frac{\partial}{\partial x} \hat{r}_{12} \left[ \int_{-1}^{1} \int_{-1}^{1} \frac{\partial^2}{\partial x \partial y} \hat{u}_1(s, \hat{y}) d\hat{y} d\hat{t} \right] d\hat{x} \right|^2 \\
\leq C h^2 \left( \sum_{K \in T_h} \left\| \frac{\partial}{\partial x} \tau_{12} \right\|_{0, K}^2 \right) \left( \sum_{K \in T_h} \left\| \frac{\partial^2}{\partial x \partial y} \hat{u}_1 \right\|_{0, K}^2 \right) \\
= C h^2 \left( \sum_{K \in T_h} \left\| \frac{\partial}{\partial x} \tau_{12} \right\|_{0}^2 \frac{h^2}{2^2} \left\| \frac{\partial^2}{\partial x \partial y} \hat{u}_1 \right\|_{0}^2 \right) \\
\leq C h^4 |\tau_{12}|_{1,h}^2 |u_1|_2^2.
\]
Here $| \cdot |_{1,h}$ is the elementwise semi-$H^1$ norm. A similar argument bounds the other term in (4.12) by
\[
\left| \sum_{K \in T_h} \left( \int_{e_{2,K}} - \int_{e_{4,K}} \right) \tau_{12} u_2 ds \right| \leq C h^2 |\tau_{12}|_{1,h} |u_2|_2.
\]
A combination of these two estimates with (4.11) implies
\[
|(A\sigma, \tau_h) + (\text{div}_h \tau_h, u)| \leq C h^2 |u_2|_2 |\tau_h|_{1,h}.
\]
By the inverse inequality,
\[
(4.14) \\
|(A\sigma, \tau_h) + (\text{div}_h \tau_h, u)| \leq C h |u_2|_2 \|\tau_h\|_0.
\]

**Theorem 4.3.** Let $(\sigma, u) \in \Sigma \times V$ be the exact solution of problem (1.1) and $(\tau_h, u_h) \in \Sigma_h \times V_h$ the finite element solution of (2.6). Then
\[
\|\sigma - \sigma_h\|_0 \leq C h (\|u\|_2 + \|\sigma\|_2), \\
\|\text{div}_h(\sigma - \sigma_h)\|_0 \leq C h (\|u\|_2 + \|\sigma\|_2), \\
\|u - u_h\|_0 \leq C h (\|u\|_2 + \|\sigma\|_2).
\]

**Proof.** Let
\[
Z_f = \{ \tau \in \Sigma_h \mid (\text{div}_h \tau, v) = (f, v) \quad \forall v \in V_h \}.
\]
The finite element solution $\sigma_h$ is in $Z_f$. Thus, for any $\tau \in Z_f$, it holds $\sigma_h - \tau \in Z_h$, i.e.,
\[
\text{div}_h(\sigma_h - \tau) = 0.
\]
It follows from the $K$-ellipticity (cf. (3.1)) that, for all $\tau \in Z_f$,
\[
C \|\sigma_h - \tau\|_0^2 \leq (A(\sigma_h - \tau), \sigma_h - \tau) \\
= (A(\sigma - \tau), \sigma_h - \tau) + (A(\sigma_h - \sigma), \sigma_h - \tau) \\
= (A(\sigma - \tau), \sigma_h - \tau) - (A\sigma, \sigma_h - \tau) - (\text{div}_h(\sigma_h - \tau), u_h) \\
= (A(\sigma - \tau), \sigma_h - \tau) - (A\sigma, \sigma_h - \tau) \\
= (A(\sigma - \tau), \sigma_h - \tau) - (A\sigma, \sigma_h - \tau) - (\text{div}_h(\sigma_h - \tau), u).
\]
An application of the Schwarz inequality leads to

\[ \|\sigma_h - \tau\|_{H(\text{div}, h)} = \|\sigma_h - \tau\|_0 \]

\[ \leq C \|\sigma - \tau\|_{H(\text{div}, h)} - \frac{(A\sigma, \sigma_h - \tau) + (\text{div}_h(\sigma_h - \tau), u)}{C\|\sigma_h - \tau\|_{H(\text{div}, h)}} \]

\[ = C \|\sigma - \tau\|_{H(\text{div}, h)} + \sup_{\tau_h \in \Sigma_h} \frac{(A\sigma, \tau_h) + (\text{div}_h\tau_h, u)}{C\|\tau_h\|_{H(\text{div}, h)}}. \]

By the triangle inequality,

\[ (4.15) \quad \|\sigma - \sigma_h\|_{H(\text{div}, h)} \leq C\{ \inf_{\tau \in Z_f} \|\sigma - \tau\|_{H(\text{div}, h)} + \sup_{\tau_h \in \Sigma_h} \frac{(A\sigma, \tau_h) + (\text{div}_h\tau_h, u)}{\|\tau_h\|_{H(\text{div}, h)}} \}. \]

For a given \( \tau_h \in \Sigma_h \), the discrete B-B condition \((3.2)\) ensures that the following problem has at least one solution \( \gamma_h \in \Sigma_h \), cf. \([12]\),

\[ (4.16) \quad (\text{div}_h\gamma_h, v_h) = (\text{div}_h(\sigma - \tau_h), v_h) \quad \forall \ v_h \in V_h. \]

It follows from the B-B condition \((3.2)\) that

\[ \|\gamma_h\|_{H(\text{div}, h)} \leq \frac{1}{C} \sup_{v_h \in V_h} \frac{(\text{div}_h\gamma_h, v_h)}{\|v_h\|_0} = \frac{1}{C} \sup_{v_h \in V_h} \frac{(\text{div}_h(\sigma - \tau_h), v_h)}{\|v_h\|_0} \]

\[ \leq \frac{1}{C}\|\text{div}_h(\sigma - \tau_h)\|_0. \]

The identity \((4.16)\) asserts that \( \gamma_h + \tau_h \in Z_f \). The choice \( \tau = \gamma_h + \tau_h \) in \((4.15)\) leads to

\[ (4.17) \quad \|\sigma - \sigma_h\|_{H(\text{div}, h)} \leq C\{ \inf_{\tau_h \in \Sigma_h} \|\sigma - \tau_h\|_{H(\text{div}, h)} + \sup_{\tau \in \Sigma_h} \frac{(A\sigma, \tau) + (\text{div}_h\tau, u)}{\|\tau\|_{H(\text{div}, h)}} \}. \]

That is,

\[ \|\sigma - \sigma_h\|_{H(\text{div}, h)} \leq C\{ \inf_{\tau_h \in \Sigma_h} \|\sigma - \tau_h\|_{H(\text{div}, h)} + \sup_{\tau \in \Sigma_h} \frac{(A\sigma, \tau) + (\text{div}_h\tau, u)}{\|\tau\|_{H(\text{div}, h)}} \}. \]

The first term on the right-hand side of \((4.17)\) is the approximation error. The choice \( \tau_h = \Pi_h \sigma \) with Theorem \((4.1)\) gives its upper bound. The second term on the right-hand side of \((4.17)\) is the usual consistency error for the nonconforming finite element method, which has already been bounded in Theorem \((4.2)\). A combination of these two theorems implies

\[ \|\sigma - \sigma_h\|_0 \leq Ch(\|u\|_2 + \|\sigma\|_2), \]

\[ \|\text{div}_h(\sigma - \sigma_h)\|_0 \leq Ch(\|u\|_2 + \|\sigma\|_2). \]
The rest of the proof is concerned with the estimation of \( u - u_h \). In view of the discrete B-B Condition \( \text{3.2} \), it holds, for any \( v \in V_h \),

\[
C\|u_h - v\|_0 \leq \sup_{\tau \in \Sigma_h} \frac{\| \text{div}_h \tau, u_h - v \|}{\| \tau \|_{H(\text{div}_h)}} = \sup_{\tau \in \Sigma_h} \frac{\| \text{div}_h \tau, u_h - u + u - v \|}{\| \tau \|_{H(\text{div}_h)}} \leq \sup_{\tau \in \Sigma_h} \frac{\| \text{div}_h \tau, u_h - u \|}{\| \tau \|_{H(\text{div}_h)}} + \| u - v \|_0
\]

\[
= \sup_{\tau \in \Sigma_h} \frac{\| \text{div}_h \tau, u_h \| + (A\sigma, \tau) - (A\sigma, \tau) - (\text{div}_h \tau, u)}{\| \tau \|_{H(\text{div}_h)}} + \| u - v \|_0
\]

\[
= \sup_{\tau \in \Sigma_h} \frac{A(\sigma - \sigma_h), \tau) - (A\sigma, \tau) - (\text{div}_h \tau, u)}{\| \tau \|_{H(\text{div}_h)}} + \| u - v \|_0
\]

\[
\leq \sup_{\tau \in \Sigma_h} \frac{(A\sigma, \tau) + (\text{div}_h \tau, u)}{\| \tau \|_{H(\text{div}_h)}} + C(\| \sigma - \sigma_h \|_0 + \| u - v \|_0).
\]

By \( \text{3.14} \) and the error estimation of \( \| \sigma - \sigma_h \|_0 \), the triangle inequality plus \( v = P_h u \) \( (P_h \text{ is the } L^2 \text{ projection into piecewise constant spaces}) \) yield

\[
\| u - u_h \|_0 \leq \| u - P_h u \|_0 + \| P_h u - u_h \|_0
\]

\[
\leq Ch\| u \|_2 + C(\| \sigma - \sigma_h \|_0 + \| u - P_h u \|_0)
\]

\[
\leq Ch(\| u \|_2 + \| \sigma \|_2).
\]

That completes the proof of this theorem. \( \square \)

5. THE MINIMAL ELEMENT IN ANY SPATIAL DIMENSION

Assume the domain \( \Omega \) is a unit hypercube \( [0, 1]^n \) in the \( n \)-dimensional space, which is subdivided by a uniform rectangular grid of \( N^n \) cubes:

\[
\mathcal{T}_h := \{ K_{i_1,i_2,\ldots,i_n} = [(i_1 - 1)h, i_1h] \times \cdots \times [(i_n - 1)h, i_nh], i_1, \ldots, i_n \leq N; \ h = 1/N \}
\]

The set of all \( (n - 1) \)-dimensional face hyperplanes of the triangulation \( \mathcal{T}_h \) that are perpendicular to the axis \( x_i \) is denoted by \( \mathcal{E}_{n-1,i} \). That is

\[
\mathcal{E}_{n-1,i} = \{ [(i_1 - 1)h, i_1h] \times \cdots \times [(i_{i-1} - 1)h, i_{i-1}h] \times [i_ih] \times \cdots \times [(i_n - 1)h, i_nh], 1 \leq i_1, \ldots, i_n \leq N, 0 \leq i \leq N \}
\]

The internal hyperplanes are denoted by

\[
\mathcal{E}_{n-1,i}(\Omega) = \mathcal{E}_{n-1,i} \cap \Omega.
\]

The set of all \( (n - 2) \)-dimensional mid-surface hyperplanes (orthogonal to both \( x_i \) and \( x_j \) axes) are denoted by

\[
\mathcal{E}_{n-2,ij} = \{ [(i_1 - 1)h, i_1h] \times \cdots \times [i_ih] \times \cdots \times [(i_j - 1/2)h] \times \cdots \times [(i_n - 1)h, i_nh], 1 \leq i_1, \ldots, i_n \leq N, 0 \leq i \leq N \}
\]

\[
\cup \{ [(i_1 - 1)h, i_1h] \times \cdots \times [(i_i - 1/2)h] \times \cdots \times [i_ih] \times \cdots \times [(i_n - 1)h, i_nh], 1 \leq i_1, \ldots, i_n \leq N, 0 \leq i_i \leq N \}.
\]
In addition, define $\mathcal{E}_{n-2,ij}(K) := \mathcal{E}_{n-2,ij} \cap \partial K$ for any $K \in \mathcal{T}_h$. In 2D, these sets are

\[
\begin{align*}
\mathcal{E}_{1,1} &= \{ \text{all edges in } \mathcal{T}_h \text{ perpendicular to } x_1 \}, \\
\mathcal{E}_{1,2} &= \{ \text{all edges in } \mathcal{T}_h \text{ perpendicular to } x_2 \}, \\
\mathcal{E}_{0,12} &= \{ \text{all mid-points of edges in } \mathcal{T}_h \}.
\end{align*}
\]

In 3D, they are

\[
\begin{align*}
\mathcal{E}_{2,i} &= \{ \text{all squares in } \mathcal{T}_h \text{ perpendicular to } x_i \}, \quad 1 \leq i \leq 3, \\
\mathcal{E}_{1,ij} &= \{ \text{all mid-square edges of squares in } \mathcal{E}_{2,i} \text{ and } \mathcal{E}_{2,j}, \\
&\quad \text{parallel to } x_k \}, \quad i \neq j \neq k \in \{1, 2, 3\}.
\end{align*}
\]

In $n$ space-dimension, the symmetric tensor space is defined in (1.2). The discrete stress space is defined by

\[
\Sigma_h := \left\{ (\tau_{ij})_{n \times n} \in L^2(\Omega, \mathbb{R}^{n \times n}) \mid \tau_{ij} = \tau_{ji}; \quad \tau_{ij}|_K \in \text{span}\{1, x_i\}, \tau_{ij} \text{ is continuous on } E_i \in \mathcal{E}_{n-1,i}; \quad \tau_{ij}|_K \in \text{span}\{1, x_i, x_j\}, \tau_{ij} \text{ is continuous on } E_{ij} \in \mathcal{E}_{n-2,ij}(\Omega) \right\}.
\]

Some comments are in order for this family of minimal finite element spaces.

**Remark 5.1.** The normal stress $\tau_{ii}$ is a constant on each $(n-1)$-dimensional hyper-plane $E_i \in \mathcal{E}_{n-1,i}$. In addition, for the case $n = 1$, $\Sigma_h$ is

\[
\{ \tau_{11} \in L^2(\Omega, \mathbb{R}) \mid \tau|_K \in \text{span}\{1, x\} \text{ is continuous at the nodes } \} \subset H^1(\Omega),
\]

the 1D Raviart-Thomas space, which is the only conforming space in this family.

**Remark 5.2.** The dimension of the space

\[
\Sigma_{h,ij} := \{ \tau_{ij} \in L^2(\Omega, \mathbb{R}) \mid \tau_{ij}|_K \in \text{span}\{1, x_i, x_j\}, \tau_{ij} \text{ is continuous on } E_{ij} \in \mathcal{E}_{n-2,ij}(\Omega) \}
\]

is

\[
N^{n-2}((n + 1)^2 - 1) = N^n + 2N^{n-1}.
\]

see [25] for more details for 2D.

Let us give the local basis for $\tau_{ii}$ and but a local frame (not basis) for $\tau_{ij}$ on an element $K := K_{i_1,i_2,\ldots,i_n} \in \mathcal{T}_h$. Define, for $(x_1, \ldots, x_n) \in K$,

\[
\psi^{(k)}_{ii,K}(x_1, \ldots, x_n) = \hat{\psi}^{(k)} \left( \frac{x_i - (i_j - 1/2)h}{h/2} \right), \quad k = 0, 1,
\]

where

\[
\hat{\psi}^{(0)}(\hat{x}) = \frac{1 - \hat{x}}{2}, \quad \hat{\psi}^{(1)}(\hat{x}) = \frac{1 + \hat{x}}{2}, \quad \hat{x} \in [-1, 1].
\]

Define, for $k = 0, 1, 2, 3$, for $(x_1, \ldots, x_n) \in K$,

\[
\phi^{(k)}_{ij,K}(x_1, \ldots, x_n) = \hat{\phi}^{(k)} \left( \frac{x_i - (i_j - 1/2)h}{h/2}, \frac{x_j - (i_j - 1/2)h}{h/2} \right),
\]

where (cf. Figure 3), for $(\hat{x}, \hat{y}) \in [-1, 1]^2$,

\[
\begin{align*}
\hat{\phi}^{(0)}(\hat{x}, \hat{y}) &= \frac{1 - \hat{x} - \hat{y}}{4}, & \hat{\phi}^{(1)}(\hat{x}, \hat{y}) &= \frac{1 + \hat{x} - \hat{y}}{4}, \\
\hat{\phi}^{(2)}(\hat{x}, \hat{y}) &= \frac{1 + \hat{x} + \hat{y}}{4}, & \hat{\phi}^{(3)}(\hat{x}, \hat{y}) &= \frac{1 - \hat{x} + \hat{y}}{4}.
\end{align*}
\]
Note that the above four functions are not linearly independent. In fact,
\[ \hat{\phi}(0) - \hat{\phi}(1) + \hat{\phi}(2) - \hat{\phi}(3) \equiv 0. \]

Then the finite element space can be alternatively defined by
\[ \Sigma_h = \left\{ (\tau_{ij})_{n \times n} \in L^2(\Omega, \mathbb{R}^{n \times n}) \mid \tau_{ij} = \tau_{ji} ; \right\} \]
\[ \tau_{ii}|_K = \sum_{k=0}^{1} \tau_{ii}(E^{(k)}_{n-1,i}(K))\psi_{ii, K}(x_1, \ldots, x_n) ; \]
\[ \tau_{ij}|_K = \sum_{k=0}^{3} p_{ij}(E^{(k)}_{n-2}(K))\phi_{ij, K}(x_1, \ldots, x_n) \} . \]

Here \( \tau_{ii}(E^{(k)}_{n-1,i}(K)) \) are the values of \( \tau_{ii} \) at the centers of the \( (n - 1) \)-dimensional hyperplanes of \( K = K_{i_1, \ldots, i_n} \):

\[ E^{(k)}_{n-1,i}(K) = \begin{pmatrix} (i_1 - \frac{1}{2})h \\ \vdots \\ (i_{n-1} - \frac{1}{2})h \\ (i_n - \frac{1}{2})h \end{pmatrix}, \quad k = 0, 1; \]

\[ p_{ij}(E^{(k)}_{n-2}(K)) \in \mathbb{R} \] are some parameters associated to the center-point of four \( (n-2) \)-dimensional hyperplanes of \( K \) which are continuous on the four (two on the boundary) \( n \)-cubes sharing the point:

\[ E^{(k)}_{n-2}(K) = \begin{pmatrix} (i_1 - \frac{1}{2})h & (i_1 - \frac{1}{2})h & (i_1 - \frac{1}{2})h & (i_1 - \frac{1}{2})h \\ \vdots & \vdots & \vdots & \vdots \\ (i_{i_2} - 0)h & (i_{i_2} - 1)h & (i_{i_2} - 1)h & (i_{i_2} - 0)h \\ \vdots & \vdots & \vdots & \vdots \\ (i_{i_3} - 0)h & (i_{i_3} - 1)h & (i_{i_3} - 1)h & (i_{i_3} - 0)h \\ \vdots & \vdots & \vdots & \vdots \\ (i_{i_n} - \frac{1}{2})h & (i_{i_n} - \frac{1}{2})h & (i_{i_n} - \frac{1}{2})h & (i_{i_n} - \frac{1}{2})h \end{pmatrix} \]

As in 2D, the discrete displacement space is
\[ V_h = \{ v \in L^2(\Omega, \mathbb{R}^n) \mid v|_K \text{ is a constant vector} \} . \]

In particular, the dof of the 3D mixed element is plotted in Figure 2.

In the \( n \)-dimension, since \( \text{div}_h \Sigma_h \subset V_h \), the K-ellipticity is proved exactly the same way as in 2D. The explicit construction proof of the discrete B-B condition can be divided into \( n \) essentially 1-dimensional construction proofs similar to that for the 1D Raviart-Thomas element of the 1D Poisson equation, see Section 3 for more details for 2D. For the consistency error in 1D, the proof remains the same except there is a multiple summation instead of 2-index summation. All the analysis in 2D remains the same for \( n \)-D.

### 6. The pure traction problem

This section considers the pure traction problem, i.e., the stress space is subject to zero Neumann boundary condition while no boundary condition on the displacement. In practice, part of elasticity body should be located, i.e, the displacement has a Dirichlet boundary condition on some non-zero measure boundary. But the pure traction problem is the most difficult one in mathematical analysis. A similar proof for Theorem 6.1 can prove it for partial displacement problems. For ease of presentation, details are
presented only for two dimensions. Note that the argument in any dimension is similar. The main idea is to use the macro-element technique where we construct a mass-preserving quasi-interpolation operator.

Let \( RM \) be the rigid motion space in two dimensions, which reads

\[
RM := \text{span}\left\{ \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, \begin{pmatrix} i \\ y \\ -x \end{pmatrix} \right\}.
\]

Consider a pure traction problem:

\[
\begin{align}
\text{div}(A^{-1} \epsilon(u)) &= f & \text{in } \Omega = (0,1)^2, \\
\epsilon(u) \cdot n &= 0 & \text{on } \Gamma = \partial \Omega, \\
(u,v) &= 0 & \forall v \in RM.
\end{align}
\]

By the same discretization of uniform square grid \( \mathcal{T}_h \) with \( h = 1/N \) as in §2, the finite element equations (2.6) remain the same except the spaces are changed with boundary and rigid-motion free conditions:

\[
\begin{align}
(A \sigma_h, \tau) + (\text{div}_h \tau, u_h) &= 0 & \forall \tau \in \Sigma_h, \\
(\text{div}_h \sigma_h, v) &= (f, v) & \forall v \in V_h,
\end{align}
\]

where

\[
\Sigma_h = \{ \sigma = \begin{pmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{12} & \sigma_{22} \end{pmatrix} : \sigma(m_e) \cdot n = 0 \forall e \in (\mathcal{E}_h \cap \Gamma) \},
\]

\[
V_h = \{ v = \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} : (v, w) = 0 \forall w \in RM \}.
\]

Here \( m_e \) is the mid-point of an edge \( e \), and \( \Sigma_h \) and \( V_h \) are defined in (2.4) and (2.5), respectively. The earlier analysis remains the same except the discrete B-B condition (3.3) as the stress space \( \Sigma_{h,0} \) is much smaller than before.

**Theorem 6.1.** The following discrete B-B condition holds uniformly,

\[
\inf_{v_h \in V_{h,0}} \sup_{\sigma_h \in \Sigma_{h,0}} \frac{(\text{div}_h \sigma_h, v_h)}{\parallel \sigma_h \parallel_{H(\text{div}_h)} \parallel v_h \parallel_0} \geq C.
\]

**Proof.** Let \( v_h = ((v_h)_1, (v_h)_2) = \sum (v_{h,ij}) \phi_{ij} \) as in (3.3), where \( (v_{h,ij}) = ((v_{h,1,ij}), (v_{h,2,ij})) \) is the constant value of \( v_h \) on square \( K_{ij} \). With the boundary condition on the stress, it is impossible to match \( (v_h)_1 \) by \( \partial_{\tau_{11}} \) alone as in (3.4). That is, because the dof of \( (v_{h,1}) \) is \( n^2 - 1.5 \) (due to a mixed constraint with the second component \( (v_{h,2}) \)), but the dof of \( \{ \tau_{11} \} \) is only \( n(n-1) \). This indicates that the help from \( \partial_{\tau_{12}} \) is indispensable. But the traditional trick of interpolating smooth B-B stress function does not work here as \( (\tau_{12}) \) does not have enough dof. In other words, the support of \( \tau_{21} \) is non-local, at least on four neighboring squares. Given \( v_h \), a discrete B-B stress function will be constructed in two steps. First, a macro-element technique will produce a \( \sigma_h \) globally so that \( v_h - \text{div}_h \sigma_h \) is rigid-motion free on each \( (2 \times 2) \) macro-element \( K_{2i,2j,2h} := [x_{2i}, x_{2i+1}] \times [y_{2j}, y_{2j+1}] \). In a second step, construct, macro-element by macro-element, a \( \sigma_h \) locally by internal dof only, so that \( \text{div}_h \sigma_h = v_h - \text{div}_h \sigma_h \).

To this end, define a local rigid-motion space on each macro-element \( K_{2i,2j,2h} \)

\[
R_{ij} = \text{span}\{ \phi_{1,ij}^r, \phi_{2,ij}^r, \phi_{3,ij}^r \},
\]

where \( \phi_{1,ij}^r \) are defined in Figure 5 piecewise constant functions. Assume \( N \) is an even integer and decompose \( v_h \) into two parts, a local rigid-motion and a global rigid-motion-free part,

\[
v_h = \tilde{v}_h + \bar{v}_h, \quad \bar{v}_h = P_{L^2(R_{ij})} v_h \quad \text{for } 0 \leq i, j \leq N/2 - 1.
\]

Here the projection \( P_{L^2(R_{ij})} \) is defined as

\[
\int_{K_{2i,2j,2h}} P_{L^2(R_{ij})} v_h \cdot \phi_{m,ij}^r dx dy = \int_{K_{2i,2j,2h}} v_h \cdot \phi_{m,ij}^r dx dy, \quad m = 1, 2, 3.
\]
To construct $\tilde{\sigma}_h$, consider the pure traction PDE (6.1a) with $f = \tilde{v}_h$ with the solution $u \in H^2(\Omega)$. Let 
\[
\sigma = A^{-1} \varepsilon(u) \in H^1(\Omega).
\]
Then
\[
div \sigma = \tilde{v}_h, \quad \|\sigma\|_{H(div)} \leq C\|\tilde{v}_h\|_0.
\] (6.6)

![Figure 5. Nodal values of three orthogonal basis functions, \{\phi_{m,ij}, m = 1, 2, 3\}, of the rigid-motion space on macro-element \(K_{2i,2j,2h} := [x_{2i}, x_{2i+2}] \times [y_{2j}, y_{2j+2}]\), cf. (6.4).](image)

![Figure 6. Interpolation nodes for the Scott-Zhang \(C^0\)-Q1 I\(_h\), I\(_E\)h, cf. (6.7) and I\(_c\)h, cf. (6.8).](image)

For the analysis, we need a mass-preserving quasi-interpolation operator. This will be achieved in four steps. First, let $I_h$ be the boundary-condition preserving Scott-Zhang operator from $[26]$, which interpolates $H^1_0$ functions to $C^0_0(\Omega)$-Q1($T_h$) functions, shown in Figure 5. Then, we correct the mid-point values of edges of macro-elements to get a mass-preserving on each edge of each macro-element $K_{2i,2j,2h}$. Let $m_E$ be the mid-point of edge $E$ of $K_{2i,2j,2h}$, which is also a vertex of $T_h$. Define the associated nodal basis function of the conforming bilinear element by
\[
\theta_E(m_E) = 1, \quad \theta_E(q) = 0 \text{ for other vertexes } q \text{ of } T_h.
\]

Let
\[
c_E = \left(\int_E (v - I_h v) ds \right) / \int_E \theta_E ds.
\]

Define $I_h^E : H_0^1(\Omega) \to C^0_0(\Omega)$-Q1($T_h$) by
\[
I_h^E v = I_h v + \sum_E c_E \theta_E.
\] (6.7)

Third, we correct the center value of $I_h^E v$ on each macro-element. Let $m_c$ be the center of macro-element $K_{2i,2j,2h}$, which is also a vertex of $T_h$. Let the $Q_1$ nodal basis function $\theta_{ij}$ for vertex $m_c$ be similarly defined as $\theta_E$. Define
\[
c_{ij} = \left(\int_{E_{1,ij}} (v - I_{2,h} v) ds + \int_{E_{2,ij}} (v - I_{2,h} v) ds \right) / \left(\int_{E_{1,ij}} \theta_{ij} ds + \int_{E_{2,ij}} \theta_{ij} ds \right),
\]
where \( E_{1,ij} = [x_{2i}, x_{2i+2}] \times \{y_{2j+1}\} \) and \( E_{2,ij} = \{x_{2i+1}\} \times [y_{2j}, y_{2j+2}] \) are two intervals in the interior of \( K_{2i,2j,2h} \) that take \( m_c \) as their mid-points, cf. Figure 6. Define \( I_h^E : H^1_0(\Omega) \to C_0^0(\Omega)-Q_1(T_h) \) by

\begin{equation}
(6.8) \quad I_h^E v = I_h^v + \sum_{ij} c_{ij} \theta_{ij}.
\end{equation}

Finally, define \( \Pi_{12} : H^1_0(\Omega) \to W_{h,0} := \{w \in W_h | \ w(m_c) = 0 \ \forall e \in \mathcal{E}_h \cap \Gamma\} \) by

\begin{equation}
(6.9) \quad \Pi_{12} v := \Pi_{12} I_h^v \text{ for any } v \in H^1_0(\Omega).
\end{equation}

Since \( \int_E \Pi_{12} I_h^v ds = \int_E I_h^v ds \) for any \( e \in \mathcal{E}_h \), the definition of the interpolation operator \( \Pi_{12} \) leads to

\begin{equation}
(6.10) \quad \int_E \Pi_{12} v ds = \int_E v ds \text{ and } \int_{E_{1,ij}} (v - \Pi_{12} v) ds + \int_{E_{2,ij}} (v - \Pi_{12} v) ds = 0,
\end{equation}

for any \( E \subset \partial K_{2i,2j,2h} \) and any macro-element \( K_{2i,2j,2h} \). In addition,

\begin{equation}
(6.11) \quad \|\nabla_h \Pi_{12} v\|_0 \leq C \|\nabla v\|_0.
\end{equation}

Then \( \tilde{\sigma}_h \) is defined as

\begin{align}
(6.12) \quad & \tilde{\sigma}_{11} = \Pi_{11} \sigma_{11}, \\
(6.13) \quad & \tilde{\sigma}_{22} = \Pi_{22} \sigma_{22}, \\
(6.14) \quad & \tilde{\sigma}_{12} = \Pi_{12} \sigma_{12},
\end{align}

where \( \Pi_{11}, \Pi_{22} \) and \( \Pi_{12} \) are defined in (4.2), (4.3) and (6.9), respectively.

We verify next, for \( \tilde{\sigma}_h \) defined in (6.12)–(6.14),

\begin{equation}
\int_{K_{2i,2j,2h}} (\text{div}_h \tilde{\sigma}_h - v_h) \cdot \phi_{m,ij}^r \ dx \ dy = 0, \quad m = 1, 2, 3,
\end{equation}

for \( 0 \leq i, j < N/2 \). Note that \( \text{div}_h \tilde{\sigma}_h \neq \hat{v}_h \) in general, though \( \text{div} \sigma = \hat{v}_h \). From (4.2), (4.3), (6.9) and (6.10), and integrations by parts it follows

\begin{align}
\int_{x_{2i}}^{x_{2i+2}} \int_{y_{2j}}^{y_{2j+2}} & \text{div}_h (\sigma - \tilde{\sigma}_h) \cdot \phi_{1,ij}^r \ dy \ dx \\
= & \int_{y_{2j}}^{y_{2j+2}} (I - \Pi_{11}) [\sigma_{11}(x_{2i+2}, y) - \sigma_{11}(x_{2i}, y)] \ dy \\
+ & \int_{x_{2i}}^{x_{2i+2}} (I - \Pi_{12}) [\sigma_{12}(x, y_{2j+2}) - \sigma_{12}(x, y_{2j})] \ dx = 0.
\end{align}

Symmetrically,

\begin{equation}
\int_{x_{2i}}^{x_{2i+2}} \int_{y_{2j}}^{y_{2j+2}} \text{div}_h (\sigma - \tilde{\sigma}_h) \cdot \phi_{2,ij}^r \ dy \ dx = 0.
\end{equation}
We match next the following stress: 
\[ \sigma \]

Note that the four mid-edge values of \( \bar{\sigma} \) for the last preserved value, as \( \text{div} \) by parts it follows

\[
\int_{x_{2i}}^{x_{2i+2}} \int_{y_{2j}}^{y_{2j+2}} \text{div}_h (\sigma - \bar{\sigma}_h) \cdot \phi_{5,ij}^c \, dy \, dx \\
= \int_{y_{2j}}^{y_{2j+2}} (I - \Pi_{11}) [\sigma_{11}(x_{2i+2}, y) - \sigma_{11}(x_{2i}, y)] \, dy \\
- \int_{y_{2j}}^{y_{2j+2}} (I - \Pi_{11}) [\sigma_{11}(x_{2i+2}, y) - \sigma_{11}(x_{2i}, y)] \, dy \\
+ \int_{x_{2i}}^{x_{2i+1}} (I - \Pi_{22}) [\sigma_{22}(x, y_{2j+2}) - \sigma_{22}(x, y_{2j})] \, dx \\
- \int_{x_{2i}}^{x_{2i+1}} (I - \Pi_{22}) [\sigma_{22}(x, y_{2j+2}) - \sigma_{22}(x, y_{2j})] \, dx \\
+ \int_{y_{2j+1}}^{y_{2j+2}} (I - \Pi_{12}) [\sigma_{12}(x, y_{2j+2}) - \sigma_{12}(x, y_{2j}) - 2\sigma_{12}(x, y_{2j+1})] \, dx \\
+ \int_{y_{2j}}^{y_{2j+2}} (I - \Pi_{12}) [2\sigma_{12}(x_{2i+1}, y) - \sigma_{12}(x_{2i+2}, y) - \sigma_{12}(x_{2i}, y)] \, dy = 0.
\]

Thus

\[
[v_h - \text{div}_h \bar{\sigma}_h]_{K_{2i,2j,2h}} \perp R_{ij} \quad 0 \leq i, j < N/2.
\]

We match next \([v_h - \text{div}_h \bar{\sigma}_h]\) on each macro-element \(K_{2i,2j,2h}\) by the divergence of internal 5 dof of discrete stress:

\[
\bar{\sigma}_{11,2i+1,2j+\frac{1}{2}}, \quad \bar{\sigma}_{11,2i+1,2j+\frac{3}{2}}, \quad \bar{\sigma}_{12,2i+1,2j+\frac{1}{2}}, \quad \bar{\sigma}_{22,2i+1,2j+\frac{1}{2}}, \quad \bar{\sigma}_{22,2i+1,2j+\frac{5}{2}},
\]

where \(\bar{\sigma}_{11,2i+1,2j+\frac{1}{2}}\) denotes the value of \(\bar{\sigma}_{11}\) at \(((2i+1)h, (2j+\frac{1}{2})h)\) and other notations are defined similarly. Note that the four mid-edge values of \(\bar{\sigma}_{12}\) are the same. Here on each macro-element, \([v_h - \text{div}_h \bar{\sigma}_h]\) is in the following space

\[(6.15) \quad M_{ij} = \text{span}\{\phi_{m,ij}^c, \ m = 1, 2, 3, 4, 5\}\]

where \(\phi_{m,ij}^c\) are defined in Figure 7.

---

**Figure 7.** Nodal values of basis functions \(\{\phi_{m,ij}^c, \ 1 \leq m \leq 5\}\) in \(M_{ij}\) on macro-element \(x_{2i} \leq x \leq x_{2i+2}, y_{2j} \leq y \leq y_{2j+2}\), cf. (6.15).

On each macro-element, define 5 stress functions to match the 5 basis functions of \(M_{ij}\) such that

\[
\text{div}_h \sigma_{m,ij} = \phi_{m,ij}^c.
\]
Each such a function is denoted by a vector of its nodal values:

\[
\frac{1}{h} \sigma_{m,ij} = \begin{pmatrix}
\bar{\sigma}_{11,2i+1,2j+1/2} \\
\bar{\sigma}_{11,2i+1,2j+3/2} \\
\bar{\sigma}_{12,2i+1,2j+1/2} \\
\bar{\sigma}_{22,2i+1,2j+1/2} \\
\bar{\sigma}_{22,2i+3/2,2j+1}
\end{pmatrix} = \begin{pmatrix}
-1 \\
0 \\
0 \\
0 \\
0
\end{pmatrix}, \begin{pmatrix}
0 \\
1 \\
0 \\
0 \\
0
\end{pmatrix}, \begin{pmatrix}
1/2 \\
-1 \\
1/2 \\
1/2 \\
1/2
\end{pmatrix}, \begin{pmatrix}
-1 \\
-1 \\
-1 \\
-1 \\
0
\end{pmatrix}, \begin{pmatrix}
0 \\
0 \\
0 \\
0 \\
0
\end{pmatrix},
\]

for \(1 \leq m \leq 5\). A linear expansion \(v_h - \text{div}_h \bar{\sigma}_h\) on \(K_{2i,2j,h}\) is defined by \(5\) functions \(c_{m,ij} \phi_{m,ij}^c\) such that \(\bar{\sigma}_h(x, y) = \sum_{m=1}^{5} c_{m,ij} \sigma_{m,ij}\), \((x, y) \in K_{2i,2j,h}\).

Thus

\[
\text{div}_h \bar{\sigma}_h = v_h - \text{div}_h \bar{\sigma}_h \quad \text{and} \quad \|\bar{\sigma}_h\|_0 \leq C \|v_h\|_0.
\]

This stability is obtained by the standard scaling argument as all norms on 5-dimensional space \(M_{ij}\) are equivalent.

The final \(\sigma_h\) for \(v_h\) is defined as

\[
\sigma_h = \bar{\sigma}_h + \tilde{\bar{\sigma}}_h.
\]

As \(\text{div}_h \sigma_h = v_h\), by (6.11) and (6.16), the discrete B-B condition holds uniformly.

7. Numerical tests

Two examples in 2D and one in 3D are presented to demonstrate the methods. These are pure displacement problem with a homogeneous boundary condition that \(u \equiv 0\) on \(\partial \Omega\). Assume the material is isotropic in the sense that

\[
A \sigma = \frac{1}{2\mu} \left( \sigma - \frac{\lambda}{2\mu + n\lambda} \text{tr}(\sigma)\delta \right) \quad n = 2, 3,
\]

where \(\delta = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}\), and \(\mu\) and \(\lambda\) are the Lamé constants such that \(0 < \mu_1 \leq \mu \leq \mu_2\) and \(0 < \lambda < \infty\).

In 2D, let the exact solution on the unit square \([0, 1]^2\) be

\[
u = \begin{pmatrix} 4x(1-x)y(1-y) \\
-4x(1-x)y(1-y) \end{pmatrix},
\]

and

\[
u = \begin{pmatrix} e^{x-y}x(1-x)y(1-y) \\
\sin(\pi x)\sin(\pi y) \end{pmatrix}.
\]

Notice that the second example is from [31].

In 2D, the parameters in (7.1) are chosen as

\[
\lambda = 1 \quad \text{and} \quad \mu = \frac{1}{2}.
\]

Then, the true stress function \(\sigma\) and the load function \(f\) are defined by the equations in (1.1), for the given solution \(u\).

In the computation, the level one grid is the given domain, a unit square or a unit cube. Each grid is refined into a half-size grid uniformly, to get a higher level grid, see the first column in Table 1. In Table 1 the errors and the convergence order in various norms are listed for the true solution (7.2). Here and in rest tables in the section, \(I_h\) is the usual nodal interpolation operator. For example, \(I_h u_1(x_1 + h/2, y_j + h/2) = u_1(x_1 + h/2, y_j + h/2), I_h \sigma_{11}(x_i, y_j + h/2) = \sigma_{11}(x_i, y_j + h/2), \) and \(I_h \sigma_{12} = \Pi_{12} \sigma_{12}\), defined in (2.11). An
The error and the order of convergence, for (7.2).

|   | $||I_h u - u_h||_0$ | $h^n$ | $||I_h \sigma - \sigma_h||_0$ | $h^n$ | $||\text{div}(I_h \sigma - \sigma_h)||_0$ | $h^n$ |
|---|-------------------|------|-----------------------------|------|---------------------------------|------|
| 1 | 0.05893           | 0.0  | 0.72887                     | 0.0  | 1.41421356                      | 0.0  |
| 2 | 0.02447           | 1.3  | 0.24585                     | 1.6  | 0.35355339                      | 2.0  |
| 3 | 0.00714           | 1.8  | 0.06587                     | 1.9  | 0.08838835                      | 2.0  |
| 4 | 0.00190           | 1.9  | 0.01708                     | 1.9  | 0.02299709                      | 2.0  |
| 5 | 0.00048           | 2.0  | 0.00440                     | 2.0  | 0.00552427                      | 2.0  |
| 6 | 0.00012           | 2.0  | 0.00113                     | 2.0  | 0.00138106                      | 2.0  |
| 7 | 0.00003           | 2.0  | 0.00029                     | 2.0  | 0.00034526                      | 2.0  |

order 2 convergence is observed for both displacement and stress, see Table 1. However, Theorem 4.3 only shows the first order convergence. Further studies on this superconvergence should be performed.

The next example, (7.3), of Yi [31] is implemented for a comparison. The finite element errors and the order of convergence are listed in Table 2. An order 2 convergence is again observed. Notice that, see Figure 1, the minimal element of this paper has a much less dof than that of Yi, but has one order higher of convergence.

|   | $||I_h u - u_h||_0$ | $h^n$ | $||I_h \sigma - \sigma_h||_0$ | $h^n$ | $||\text{div}(I_h \sigma - \sigma_h)||_0$ | $h^n$ |
|---|-------------------|------|-----------------------------|------|---------------------------------|------|
| 1 | 0.03619           | 0.0  | 3.08021                     | 0.0  | 12.20143741                     | 0.0  |
| 2 | 0.09843           | 0.0  | 0.54275                     | 2.5  | 2.36338456                      | 2.4  |
| 3 | 0.02594           | 1.9  | 0.15169                     | 1.9  | 0.63139891                      | 1.9  |
| 4 | 0.00664           | 2.0  | 0.03964                     | 1.9  | 0.16050210                      | 2.0  |
| 5 | 0.00167           | 2.0  | 0.01014                     | 2.0  | 0.04029305                      | 2.0  |
| 6 | 0.00042           | 2.0  | 0.00258                     | 2.0  | 0.01008376                      | 2.0  |

As a third example, we compute a 3D solution for the following exact solution:

\[
(7.4)\quad u = \begin{pmatrix} 16x(1-x)y(1-y)z(1-z) \\ 32x(1-x)y(1-y)z(1-z) \\ 64x(1-x)y(1-y)z(1-z) \end{pmatrix},
\]

on the unit cube $[0,1]^3$. This time, the parameters in (7.1) are taken as

$\lambda = 1, \quad \mu = \frac{1}{2}$ and $n = 3$.

Again the order of convergence is still one higher than what is proved in this paper, see Table 3.

|   | $||I_h u - u_h||_0$ | $h^n$ | $||I_h \sigma - \sigma_h||_0$ | $h^n$ | $||\text{div}(I_h \sigma - \sigma_h)||_0$ | $h^n$ |
|---|-------------------|------|-----------------------------|------|---------------------------------|------|
| 1 | 0.16366           | 0.0  | 3.64496                     | 0.0  | 8.94883415                      | 0.0  |
| 2 | 0.07716           | 1.1  | 0.89446                     | 2.0  | 1.73418255                      | 2.4  |
| 3 | 0.02332           | 1.7  | 0.23153                     | 1.9  | 0.42577123                      | 2.0  |
| 4 | 0.00628           | 1.9  | 0.05946                     | 2.0  | 0.10668050                      | 2.0  |
| 5 | 0.00161           | 2.0  | 0.01518                     | 2.0  | 0.02628774                      | 2.0  |
As the last example, we compute the pure traction problem (6.1a) with the exact solution
\[ u = \begin{bmatrix} 100x^2(1-x)^2y^2(1-y)^2 - \frac{1}{9} \\ -1 \end{bmatrix}. \]

The matrix \( A \) is same as that in the first two examples. Our new finite element has no problem in solving the pure traction problems. The convergence results are listed in Table 4.

### Table 4. The errors and the order of convergence for the pure traction problem (7.5).

| \( h^n \) | \( h^n \) | \( h^n \) | \( h^n \) |
|---|---|---|---|
| 2 | 0.41470 0.0 | 1.19604 0.0 | 4.14320380 0.0 |
| 3 | 0.12546 1.7 | 0.26426 2.2 | 1.10584856 1.9 |
| 4 | 0.03273 1.9 | 0.06572 2.0 | 0.28799493 1.9 |
| 5 | 0.00827 2.0 | 0.01648 2.0 | 0.07297595 2.0 |
| 6 | 0.00207 2.0 | 0.00412 2.0 | 0.01830958 2.0 |
| 7 | 0.00052 2.0 | 0.00103 2.0 | 0.00458156 2.0 |
