Graph-based reaction systems were recently introduced as a generalization of the intensely studied set-based reaction systems. They deal with simple edge-labeled directed graphs, and dynamic semantics of graph-based reaction systems is defined by graph surfing as a novel kind of graph transformation where, in a single surf step, reactions are applied to a subgraph of a given background graph yielding a successor subgraph. In this paper, we propose a categorical approach to reaction systems so that a wider spectrum of data structures becomes available on which reaction systems can be based. In this way, many types of graphs, hypergraphs, and graph-like structures are covered.

1 Introduction

Rozenberg and the first author introduced graph surfing in graph-based reaction systems as a novel kind of graph transformation in [11, 12]. They consider simple edge-labeled directed graphs. A graph-based reaction system consists of a finite background graph $B$ and a set of reactions each of which is a triple $(R, I, P)$ where $R$ and $P$ are subgraphs of $B$, called reactant and product respectively, and $I = (I_V, I_E)$ is a pair of sets of vertices and edges of $B$ respectively, called inhibitor. Such a reaction is enabled on a state $T$ being a subgraph of $B$ if $R$ is subgraph of $T$ and none of the element of $I_V$ and $I_E$ belongs to $T$. The latter allows to forbid edges without forbidding their sources and targets necessarily. All enabled reactions are applied to a state in parallel yielding the union of all their products as successor state. The iterated application of reactions form trajectories on the set of subgraphs of the background graph – the metaphorical graph surfing. Before each step, a context graph can be added to the current state so that the processing becomes interactive. Graph-based reaction systems generalize the seminal concept of set-based reaction systems that was introduced by Ehrenfeucht and Rozenberg more than 12 years ago in [6] and has been intensely studied since then (see, e.g., [3, 5, 9, 14]). Set-based reaction systems coincide with graph-based reaction systems the background graphs of which are discrete graphs and the inhibitor sets are both empty.

In this paper, we advocate a categorical approach to reaction systems by defining them over categories that provide empty subobjects, intersections and unions, $eiu$-categories for short. A wide spectrum of categories of graphs, hypergraphs and graph-like structures fit into the approach. The categorical framework is tailored in such a way that reaction systems over an $eiu$-category can be defined in close analogy to the set- and graph-based reaction systems. The ingredients of set- and graph-based reaction systems are finite sets/graphs, subsets/subgraphs including the empty set/empty graph, subset/subgraph inclusions, intersections of two subsets/subgraphs, and the unions of finite sets of subsets/subgraphs. As the categorical counterparts, we use finite objects, subobjects and subobject inclusions, as they are provided by every category, and we require a special initial object with monomorphic initial morphisms as empty subobjects, pullbacks of monomorphisms as intersections and special colimits as unions in addition. This paper continues our work on a categorical approach to reaction systems that started in [10].
where we tried to identify basic categorical notions that allow to define reaction systems generalizing
the known set- and graph-based reaction systems. The *eu*-categories introduced in the present paper
are more restrictive, but cover still all the relevant examples and provide much more useful categorical
machinery.

The paper is organized as follows. Section 2 provides the categorial framework. In Section 3 we
introduce the notion of reaction systems *eu*-categories exemplifying the conception by a reaction
system over the category of hypergraphs. In Section 4 we show that certain diagram categories are *eu-
categories such that many categories of graphs, hypergraphs and further graph-like structures turn out
to be *eu*-categories and, therefore, can be employed as base category for reaction systems. Section 5
is devoted to the question how meaningful morphisms between reaction systems over a category may look
like giving a first answer. This enables us to define a category of reaction systems over an *eu*-category.
Section 6 concludes the paper.

2 The Categorial Prerequisites

In this section, the categorical prerequisites are provided that allow us to define reaction systems over
a so-called *eu*-category in the next section. In Subsection 2.1 we recall some well-known categorical
notions including subobjects, finite objects, initial objects, pullbacks, and special colimits (cf., e.g., [7
[1,8]). Based on these concepts, we introduce the notion of an *eu*-category in Subsection 2.2

2.1 Categorial Preliminaries

A category \( C = (\text{Ob}_C, \text{Mor}_C, \circ, 1) \) consists of a class of objects \( \text{Ob}_C \), a set of morphisms \( \text{Mor}_C(A,B) \) for
each pair of objects \( A,B \in \text{Ob}_C \), an associative composition operation \( \circ : \text{Mor}_C(B,C) \times \text{Mor}_C(A,B) \to \text{Mor}_C(A,C) \) for
each triple of objects \( A,B,C \in \text{Ob}_C \), and, an identity morphism \( 1_A \in \text{Mor}_C(A,A) \) for each object \( A \in \text{Ob}_C \) such that \( f \circ 1_A = f \) and \( 1_B \circ f = f \) for each \( f \in \text{Mor}_C(A,B) \) holds.

We may write \( f : A \to B \) or \( A \underset{f}{\to} B \) for \( f \in \text{Mor}_C(A,B) \) and \( A \cong B \) for pairs of morphisms with same

domain and codomain. Let \( f : A \to B \) and \( g : B \to C \). We may write \( A \underset{f}{\to} B \underset{g}{\to} C \) instead of \( g \circ f \).

A morphism \( f : A \to B \) is a monomorphism if, for all pairs \( C \cong A \) of morphisms, \( f \circ h = f \circ k \) implies \( h = k \).

A morphism \( f : A \to B \) is an isomorphism if there exists an inverse morphism \( f^{-1} : B \to A \) with \( f^{-1} \circ f = 1_A \) and \( f \circ f^{-1} = 1_B \). Two objects \( A, B \) are isomorphic, denoted \( A \cong B \), if there is an isomorphism \( f : A \to B \).

A subobject of \( B \) for some \( B \in \text{Ob}_C \) is an equivalence class of the following equivalence of monomorphisms with codomain \( B \): Two monomorphisms \( m_1 : A_1 \to B, m_2 : A_2 \to B \) are equivalent, denoted by \( m_1 \cong m_2 \), if there is an isomorphism \( i : A_1 \to A_2 \) such that \( m_1 = m_2 \circ i \).

To deal with subobjects, we use their elements as representatives. This does not cause any problem
because most categorical concepts and constructions are unique up to isomorphism.

Given subobjects \( p_1 : P_1 \to B \) and \( p_2 : P_2 \to B \), a monomorphism \( m : P_1 \to P_2 \) is a subobject inclusion
from \( p_1 \) to \( p_2 \) if \( p_1 = p_2 \circ m \), and we may write \( p_1 \subseteq p_2 \).

An object is finite if its set of subobjects is finite.

An object \( \text{INIT} \in \text{Ob}_C \) is an initial object if there is exactly one unique morphism \( \text{init}_B : \text{INIT} \to B \)
for each object \( B \in \text{Ob}_C \).
Let \( p_1 : P_1 \to B, p_2 : P_2 \to B \) be morphisms with common codomain \( B \). A pullback \((PB(p_1, p_2), p'_1, p'_2)\) of \( p_1 \) and \( p_2 \) is defined by a pullback object \( PB(p_1, p_2) \) and morphisms \( p'_1 : PB(p_1, p_2) \to P_1 \) and \( p'_2 : PB(p_1, p_2) \to P_2 \) such that \( p_1 \circ p'_1 = p_2 \circ p'_2 \) and the following universal property holds: For each object \( Y \) with morphisms \( p''_1 : Y \to P_1 \) and \( p''_2 : Y \to P_2 \), such that \( p_1 \circ p''_1 = p_2 \circ p''_2 \), there is a unique universal morphism \( u : Y \to PB(p_1, p_2) \) such that \( p''_1 \circ u = p''_1 \) and \( p''_2 \circ u = p''_2 \). The following diagram illustrates the situation.

The dashed arrow indicates that the morphism exists uniquely.

Let \( S \) be a set of morphisms with codomain \( B \). Let \( PB(S) \) be the set of all pullbacks \((PB(p_1, p_2), p'_1 : PB(p_1, p_2) \to P_1, p'_2 : PB(p_1, p_2) \to P_2)\) of \( p_1, p_2 \) for each pair \((p_1 : P_1 \to B), (p_2 : P_2 \to B) \in S\) with \( p_1 \neq p_2 \). Then an object \( \text{COLIMIT}(PB(S)) \) together with a morphism \( p'' : P \to \text{COLIMIT}(PB(S)) \) for each \((p : P \to B) \in S\), called injection, such that \( p''_1 \circ p'' = p''_2 \circ p'' \) for each pullback \((PB(p_1, p_2), p'_1, p'_2) \in PB(S)\) is the colimit of \( PB(S) \) if the following universal property holds: For each object \( X \) together with a morphism \( \hat{p} : P \to X \) for each \((p : P \to B) \in S\) satisfying \( \hat{p} \circ p''_1 = \hat{p} \circ p''_2 \) for each pullback \((PB(p_1, p_2), p'_1, p'_2) \in PB(S)\), there exists a unique universal morphism \( m : \text{COLIMIT}(PB(S)) \to X \) such that \( m \circ p'' = \hat{p} \) for each \( p \in S \).

According to the definition, the following holds for three special cases of this colimit.

1. \( \text{COLIMIT}(PB(\emptyset)) = \text{INIT} \).
2. \( \text{COLIMIT}(PB(\{p\})) = P \) for each subobject \( p : P \to B \).
3. Given two subobjects \( p_i : P_i \to B, i = 1, 2 \), then \( \text{COLIMIT}(PB(\{p_1, p_2\})) \) together with the injections \( p''_i : P_i \to \text{COLIMIT}(PB(\{p_1, p_2\})) \) is the pushout of the pullback \((PB(p_1, p_2), p'_1, p'_2)\).

It may be noted that the universal property of the colimit yields a universal morphism \( m : \text{COLIMIT}(PB(S)) \to B \) with \( m \circ p'' = p \) for each \( p \in S \).

The following diagram illustrates the situation for three subobjects.
2.2 Empty Subobjects, Intersections and Unions

Using the notions of the previous subsection, we can now define the class of categories that are considered in this paper.

A category $C$ is an *eiu*-category if $C$ has

1. an initial object $\text{INIT}$, and
2. for every finite object $B$, pullbacks of the subobjects of $B$, as well as
3. colimits of the sets of all pairwise pullbacks of sets of subobjects of every finite object $B$

subject to the following conditions:

1. $\text{INIT}$ has only itself as subobject and the initial morphism into $B$ is a monomorphism, and
2. the universal morphism from $\text{COLIMIT}(\text{PB}(S))$ into $B$ for every set $S$ of subobjects of $B$ is a monomorphism.

We use the following notions and notations for *eiu*-categories and every of its finite objects $B$.

1. The subobject represented by the initial morphism into $B$ is called *empty subobject* of $B$ and denoted by $\text{empty}_B : \text{INIT} \to B$.
2. As pullbacks are stable under monomorphisms, the pullback morphisms $p'_i : \text{PB}(p_1, p_2) \to P_i$ of two subobjects $p_i : P_i \to B$ for $i = 1, 2$ are monomorphisms. Further, because monomorphisms are closed under composition, $p'_1 \circ p_1 = p'_2 \circ p_2$ represents a subobject of $B$ called *intersection* of $p_1$ and $p_2$ which is denoted by $p_1 \cap p_2 : P_1 \cap P_2 \to B$.
3. Given a set $S$ of subobjects of $B$, the universal morphism from $\text{COLIMIT}(\text{PB}(S))$ into $B$ represents a subobject of $B$ called *union* of $S$ which is denoted by $\text{union}(S) : \text{UNION}(S) \to B$. We may write $p_1 \cup p_2$ for the binary (effective) $\text{union}([p_1, p_2])$.

Empty subobjects, intersections and unions have some useful properties (cf. Remarks 1 and 2 in the next section). The initials e, i, and u of the three concepts are used to name the category.

**Properties 1** Let $B$ be a finite object.

1. Let $p : P \to B$ and $p_0 : P_0 \to B$ be subobjects of $B$ with $p_0 \subseteq p$. Then
   
   (a) $p \cap p_0 = p_0$.
   (b) $p \cup p_0 = p$.

   In particular, $p \cap \text{empty}_B = \text{empty}_B$ and $p \cup \text{empty}_B = p$.

2. Let $S$ be a set of subobjects of $B$. Then $\text{union}(S \cup \{\text{empty}_B\}) = \text{union}(S)$.

3. Let $S_0$ and $S$ be sets of subobjects of $B$ with $S_0 \subseteq S$. Then $\text{union}(S_0) \subseteq \text{union}(S)$.

**Proof** 1. $p_0 \subseteq p$ means that there is a monomorphism $m : R_0 \to P$ with $p \circ m = p_0$. Using this equation, it is easy to show that $(P_0, 1_{R_0}, m)$ is a pullback of $p_0$ and $p$ and $(P, m, 1_P)$ is a pushout of $1_{R_0}$ and $m$. As pullbacks and pushouts are unique up to isomorphisms, one gets $p \cap p_0 = p_0$ and $p \cup p_0 = p$ for the represented subobjects. This holds for $p_0 = \text{empty}_B$, in particular. The following diagrams illustrate the
2. If $\text{empty}_B \in S$, then $S \cup \{\text{empty}_B\} = S$ so that the statement holds in this case.

Consider now $S$ with $\text{empty}_B \notin S$. By definition, $\text{union}(S) : \text{UNION}(S) \rightarrow B$ is accompanied with a monomorphism $p'' : P \rightarrow \text{UNION}(S)$ for each $(p : P \rightarrow B) \in S$ such that $p = \text{union}(S) \circ p''$ and, for each pair $(p : P \rightarrow B), (\overline{p}, \overline{P} \rightarrow B) \in S$ with a pullback $(P \cap \overline{P}, p' : P \cap \overline{P} \rightarrow \overline{P}, \overline{p}' : P \cap \overline{P} \rightarrow \overline{P})$ of $p$ and $\overline{p}$, $p'' \circ p' = \overline{p}'' \circ \overline{p}'$. Now one can add $\text{empty}_B$ to $S$ and choose $\text{empty}_{\text{UNION}(S)} : \text{INIT} \rightarrow \text{UNION}(S)$ as monomorphism corresponding to $\text{empty}_B$. As the initial morphism is unique, one gets $\text{empty}_B = \text{union}(S) \circ \text{empty}_{\text{UNION}(S)}$ and $p'' \circ \text{empty}_P = \text{empty}_{\text{UNION}(S)} = \text{empty}_{\text{UNION}(S)} \circ 1_{\text{INIT}}$. As pointed out in Point 1 $P \cap \text{INIT}, \text{empty}_P, 1_{\text{INIT}}$ is a pullback of $p$ and $\text{empty}_B$. Altogether, this means that $\text{union}(S)$ with morphisms $p''$ plus $\text{empty}_{\text{UNION}(S)}$ equalizes all pullbacks in $PB(S \cup \{\text{empty}_B\})$. Moreover, one can show that also the universal property of $\text{union}(S \cup \{\text{empty}_B\})$ is satisfied. Let $X$ be an object with a morphism $\hat{p} : P \rightarrow X$ for each $p : P \rightarrow B$ plus the only initial morphism $\text{empty}_X : \text{INIT} \rightarrow X$ such that all pullbacks in $PB(S \cup \{\text{empty}_B\})$ are equalized, i.e., $(\ast)$ $\hat{p} \circ p' = \overline{p} \circ \overline{p}'$ for each $(P \cap \overline{P}, p', \overline{p}') \in PB(S)$ and $\hat{p} \circ \text{empty}_P = \text{empty}_X \circ 1_{\text{INIT}}$ for each pullback $(P \cap \text{INIT}, \text{empty}_P, 1_{\text{INIT}})$ for $p \in S$ and $\text{empty}_B$. Because of $(\ast)$, the universal property of $\text{union}(S)$ induces a morphism $m : \text{UNION}(S) \rightarrow X$ with $\hat{p} = m \circ p''$ for all $p \in S$. Moreover, the initiality of $\text{INIT}$ yields $\text{empty}_X = m \circ \text{empty}_{\text{UNION}(S)}$. Summarizing, $\text{union}(S)$ with the morphisms $p''$ plus $\text{empty}_{\text{UNION}(S)}$ has the property of $\text{union}(S \cup \{\text{empty}_B\})$ so that they are equal as subobjects. The situation is depicted in the following diagram.

3. Using the notation of Point 2, $\text{union}(S)$ with the morphisms $p''$ for $p \in S$ equalizes all pullbacks in $PB(S)$ and, in particular, all in $PB(S_0)$ as $S_0 \subseteq S$. Therefore, using the universal property of $\text{union}(S_0)$, there is a morphism $m : \text{UNION}(S_0) \rightarrow \text{UNION}(S)$ with $\text{union}(S) \circ m = \text{union}(S_0)$. As $\text{union}(S_0)$ is a monomorphism, $m$ is a monomorphism proving $\text{union}(S_0) \subseteq \text{union}(S)$.

**Example 1** First of all, the category **Sets** with sets as objects and mappings as morphisms is an eiu-category. This follows from well-known set-theoretic and categorial properties. The monomorphisms
are the injective mappings. Two of them with common codomain are equivalent if they have the same image. Therefore, there is a one-to-one correspondence between subobjects of a set and its subsets, and subobjects can be represented by the inclusions of subsets. In particular, the finite sets are the finite objects. The empty set \( \emptyset \) is the initial object. It has only itself as subset, and the initial morphism \( \emptyset_B : \emptyset \to B \) is injective for every set \( B \) so that \( \emptyset_B \) is the empty subobject of \( B \). Given two subsets \( P_1 \) and \( P_2 \) of a set \( B \), their set-theoretic intersection \( P_1 \cap P_2 \) together with the inclusion into \( P_1 \) and \( P_2 \) respectively is a pullback over the inclusions of \( P_1 \) and \( P_2 \) into \( B \) and, therefore, the categorial intersection. Moreover, let \( S \) be a set of subsets of a set \( B \). Then the set-theoretic union \( \bigcup_{P \in S} P \) is the smallest subset of \( B \) that contains each \( P \in S \). If \( X \) is a set and \( q_P : P \to X \) is a mapping for each \( P \in S \) such that \( q_{P_1} \) and \( q_{P_2} \) are equal on the intersection \( P_1 \cap P_2 \) for every pair \( P_1, P_2 \in S \), then \( m : \bigcup_{P \in S} P \to X \) given by \( m(y) = q_P(y) \) for \( y \in P, P \in S \) is a mapping. This proves that the inclusions of \( \bigcup_{P \in S} P \) into \( B \) has the universal property required of \( \text{union}(S) \) so that the set-theoretic union turns out to represent the categorial union.

Based on \textbf{Sets}, many further \textbf{eu-categories} can be derived (cf. Section 3). As a first example of this kind we consider the category \( \Sigma\text{-Hypergraphs} \). Its objects are \( \Sigma \)-hypergraphs and its morphisms are \( \Sigma \)-hypergraph morphisms defined as follows. A \( \Sigma \)-hypergraph \( H = (V,E,\text{att},l) \) over a given set \( \Sigma \) of labels is a system consisting of a set \( V \) of vertices, a set \( E \) of hyperedges, an attachment mapping \( \text{att} : E \to V^* \) (assigning a string of attachment vertices to each hyperedge) and a labeling mapping \( l : E \to \Sigma \). The components of \( H = (V,E,\text{att},l) \) may also be denoted by \( V_H, E_H, \text{att}_H, \) and \( l_H \) respectively. The length of the attachment is called type. A hypergraph morphism \( m \) from \( H = (V,E,\text{att},l) \) to \( H' = (V',E',\text{att}',l') \) is a pair \((f_V : V \to V', f_E : E \to E')\) of two mappings such that \( f_V^* \circ \text{att} = \text{att}' \circ f_E \) and \( l = l' \circ f_E \), where \( V^* \) is the set of all string over \( V \) and \( f_V^* : V^* \to V'^* \) is the canonical extension of \( f_V \) to strings defined by \( f_V^*(v_1 \cdots v_n) = f_V(v_1) \cdots f_V(v_n) \) for all \( v_1 \cdots v_n \in V^* \). \( H \) is a sub-\( \Sigma \)-hypergraph of \( H' \) if \( V_H \subseteq V'_H, E_H \subseteq E'_H \) and the pair of inclusions \( m = (\text{inv}_V, \text{inv}_E) \) is a hypergraph morphism.

It is not difficult to see that all the ingredients of \textbf{eu-categories} can be carried over from \textbf{Sets} to \( \Sigma\text{-Hypergraphs} \) componentwise for vertices and hyperedges. The monomorphisms are the pairs of injective mappings so that sub-\( \Sigma \)-hypergraphs correspond to subobjects, and finiteness is given by finite set components. The empty \( \Sigma \)-hypergraph \( \text{MPT} = (\emptyset,\emptyset,\emptyset_\emptyset,\emptyset_\emptyset) \) is initial so that \( \text{empty}_B : \text{MPT} \to B \) given by \( \emptyset_V : \emptyset \to V_B \) and \( \emptyset_E : \emptyset \to E_B \) is the empty subobject of each \( \Sigma \)-hypergraph \( B \). Analogously, intersection and union can be constructed componentwise.

For \( p_i : P_i \to B, i = 1,2 \) we have \( p_1 \cap p_2 : P_1 \cap P_2 \to B \) with \( P_1 \cap P_2 = \{(p_1 \cap p_2)(e) | (p_1)(e) \cap (p_2)(e) \} \), \( \text{att}_{p_1}(e) = \text{att}_p(e) \) and \( l_{p_1}(e) = l_p(e) \) for all \( e \in E_{P_1} \cap E_{P_2} \). As \( \text{att}_{p_1} \) and \( \text{att}_{p_2} \) as well as \( l_{p_1} \) and \( l_{p_2} \) are equal on the intersection \( E_{P_1} \cap E_{P_2} \), \( \text{att}_1 \) and \( l_1 \) are proper mappings.

For a set \( S \) of sub-\( \Sigma \)-hypergraphs of a \( \Sigma \)-hypergraph \( B \) we have union\( (S) : \cup_{P \in S} P \to B \) with \( \cup_{P \in S} (P) = \{(\cup_{P \in S} (P))(e) | \cup_{P \in S} (P)(e) \} \), \( \text{att}_{\cup}(e) = \text{att}_p(e) \) and \( l_{\cup}(e) = l_p(e) \) for all \( e \in E_{P}, P \in S \). As \( \text{att}_p \) and \( \text{att}_{\cup} \) as well as \( l_p \) and \( l_{\cup} \) are equal on the intersection of \( P_1 \) and \( P_2 \), \( \text{att} \) and \( l \) are well-defined.

As a further example, we consider the category \textbf{Pos} of partially ordered sets (posets for short). A poset (which can also be seen as simple acyclic transitive directed graph) is a pair \((A,R)\) consisting of a set \( A \) and a binary relation \( R \subseteq A \times A \) subject to the conditions:

- reflexivity, i.e., \((a,a) \in R\) for all \( a \in A \),
- anti-symmetry, i.e., \((a,b),(b,a) \in R\) implies \( a=b \) for all \( a,b \in A \), and
- transitivity, i.e., \((a,b),(b,c) \in R\) implies \((a,c) \in R\) for all \( a,b,c \in A \).

A morphism \( f : (A,R) \to (A',R') \) is given by an order-preserving mapping \( f : A \to A' \) meaning that \((f(a),f(b)) \in R'\) for all \((a,b) \in R\). Composition and identity are the same as in \textbf{Sets}. A morphism...
Graphs. Therefore, we replace it by a subobject counterpart as categorical objects do not provide explicit internal information like vertices and edges of the inhibitor. The graph-based inhibitor (consisting of sets of vertices and edges) has not a direct

In this section, we introduce the notion of reaction systems over an $eiu$-category. This can be done in a straightforward way by replacing every occurrence of "(sub)set/(sub)graph" in the definition of set/graph-based reaction systems by "(sub)object" with one exception: the enabledness with respect to the inhibitor. The graph-based inhibitor (consisting of sets of vertices and edges) does not have a direct
counterpart as categorical objects do not provide explicit internal information like vertices and edges of graphs. Therefore, we replace it by a subobject $i: I \to B$ of the background like reactant and product accompanied by a subobject $i_0: I_0 \to I$. This allows to require that the intersection of $i$ and a current state is included in $i_0$ so that the "complement" of $i$ and $i_0$ is forbidden.

3 Reaction Systems over $eiu$-categories

In this section, we introduce the notion of reaction systems over an $eiu$-category. This can be done in a straightforward way by replacing every occurrence of "(sub)set/(sub)graph" in the definition of set/graph-based reaction systems by "(sub)object" with one exception: the enabledness with respect to the inhibitor. The graph-based inhibitor (consisting of sets of vertices and edges) does not have a direct
counterpart as categorical objects do not provide explicit internal information like vertices and edges of graphs. Therefore, we replace it by a subobject $i: I \to B$ of the background like reactant and product accompanied by a subobject $i_0: I_0 \to I$. This allows to require that the intersection of $i$ and a current state is included in $i_0$ so that the "complement" of $i$ and $i_0$ is forbidden.

3.1 Reaction Systems over $C$

Let $C$ be an $eiu$-category. Then we can define reaction systems over $C$ in a way analogous to set-based and graph-based reaction systems.

**Definition 1.** Let $B$ be a finite object in $C$. A reaction over $B$ is a triple $a = (r: R \to B, (i: I \to B, i_0: I_0 \to I), p: P \to B)$ where $r$ and $p$ are non-empty subobjects of $B$, $i$ is a subobject of $B$ and
that all hyperedges are equally labeled and, hence, can be considered as unlabeled). Then \( \Sigma \) is a subobject of \( I \). The subobject \( r \) is called reactant, the pair \( (i, i_0) \) is called inhibitor, and \( p \) is called product. \( r, (i, i_0) \) and \( p \) may also be denoted by \( r_a, (i_a, (i_0)_a) \) and \( p_a \), respectively.

2. A state is a subobject of \( B \).

3. A reaction \( a = (r: R \to B, (i: I \to B, i_0: I_0 \to I), p: P \to B) \) is enabled on a state \( t: T \to B \), denoted by \( \text{en}_a(t) \), if \( r \subseteq t \) and \( t \cap i \subseteq i \circ i_0 \), i.e., there is a monomorphism \( s: R \to T \) with \( r = t \circ s \) and, for the intersection \( (T \cap I, i', t') \) of \( t \) and \( i \), there is a monomorphism \( s': T \cap I \to I_0 \) with \( t \cap i = i \circ i_0 \circ s' \).

4. The result of a reaction \( a \) on a state \( t \) is \( \text{res}_a(t) = p_a \) for \( \text{en}_a(t) \) and \( \text{res}_a(t) = \text{empty}_B \) otherwise.

5. Given a state \( t: T \to B \), the result of a set of reactions \( A \) on \( t \) is \( \text{res}_A(t) = \text{union}(\{\text{res}_a(t) | a \in A\}) \).

6. A reaction system over \( C \) is a pair \( \mathcal{A} = (B, A) \) consisting of some finite object \( B \), called background, and a finite set \( A \) of reactions over \( B \).

7. Given a state \( t: T \to B \), the result of \( \mathcal{A} \) on \( t \) is the result of \( A \) on \( t \). It is denoted by \( \text{res}_{\mathcal{A}}(t) \).

**Remark 1** Some basic properties of enabledness and results which are known for set- and graph-based reaction systems carry over to reaction systems over a category.

1. A current state vanishes completely. But it or some subobject of it may be reproduced by the products of enabled reactions.

2. \( \text{res}_{\mathcal{A}}(t) \) is uniquely defined for every state \( t \) so that \( \text{res}_{\mathcal{A}}(t) \) is a function on the set of states of \( B \).

3. All reactions contribute to \( \text{res}_{\mathcal{A}}(t) \) in a maximally parallel and cumulative way. There is never any conflict.

4. As the addition of the empty subobject to a union of subobjects does not change the union, \( \text{res}_A(t) = \text{res}_{\{a \in A | \text{en}_a(t)\}}(t) \) holds for all states \( t \).

5. As the intersection of a subobject and the empty subobject is empty, a reaction with an empty inhibitor, i.e., \( a = (r, (\text{empty}_B, \text{INIT}), p) \) is enabled on a state \( t \) if \( r \subseteq t \). The empty inhibitor has no effect. Therefore, the reaction is called uninhibited.

Set-based and graph-based reaction systems can be transformed into reaction systems over the categories of sets and graphs, respectively. The transformations preserve the semantics so that set-based and graph-based reaction systems fit fully into the categorical framework. In the following we discuss two reaction systems over \( \Sigma\text{-Hypergraphs} \).

### 3.2 Two Reaction Systems over \( \Sigma\text{-Hypergraphs} \)

As a first example, we model a vertex-coverability test by a family of reaction systems over the category \( \Sigma\text{-Hypergraphs} \).

Let \( H = (V, E, \text{att}, l) \) be a \( \Sigma \)-hypergraph with \( l(e) = \ast \) for some label \( \ast \in \Sigma \) for all \( e \in E \) (this means that all hyperedges are equally labeled and, hence, can be considered as unlabeled). Then \( X \subseteq V \) is a
vertex cover of \( H \) if each hyperedge has some attachment vertex in \( X \). \( H \) is \( k \)-vertex-coverable for some \( k \in \mathbb{N} \) if there is a hyperedge vertex cover of \( H \) with \( k \) elements.

The \( k \)-vertex-coverability test employs the reaction system \( \mathcal{A}_{m,n} = (B_{m,n}, A_{m,n}) \) for some \( m, n \in \mathbb{N} \) with \( m \leq n \) defined as follows. Let \( \binom{n}{m} \) be the set of all strings over \([n]\) of lengths up to \( m \). Then the complete hypergraph with twins is defined by \( CH_{m,n}^{(2)} = ([n], \binom{n}{m}) \times \{\ast, +\}, attach, lab \) with \( attach(u, \ast) = attach(u, +) = u \) and \( lab(u, \ast) = \ast \) and \( lab(u, +) = + \) for all \( u \in \binom{n}{m} \). The two parallel hyperedges \( (u, \ast) \) and \( (u, +) \) for \( u \in \binom{n}{m} \) are called twins. The background hypergraph \( B_{m,n} \) is \( CH_{m,n}^{(2)} \) extended by a \( \ast \)-flag (type-1 hyperedge) at each vertex. The set of reactions \( A_{m,n} \) contains the following elements, where, due to the one-to-one correspondence of categorial subobjects of a \( \Sigma \)-hypergraph and sub-\( \Sigma \)-hypergraphs, the subobjects are represented by the domain objects of the inclusion morphisms. The symbol “\( \cdot \)” is a shortcut for the inhibitor (empty \( B_{m,n} \), \( 1_{MPT} \)).

1. \((\overline{j}, -, \overline{j})\) for all \( j \in [n] \).

2. \((e^\ast, -, e^\ast)\) for all \( e \in \binom{n}{m} \times \{\ast, +\} \) where \( e^\ast \) is the sub-\( \Sigma \)-hypergraph of \( B_{m,n} \) induced by \( e \), i.e., \( e^\ast = (\{v_1, \ldots, v_l\}, \{e\}, attach|_{\{e\}}, lab|_{\{e\}}) \) with \( attach(e) = v_1 \cdots v_l \) for \( j = 1, \ldots, l \).

3. \((\overline{j}, -\overline{1}, 1, j, -\overline{1}, \overline{j})\) for all \( j \in [n] \).

4. \(((u, \ast)^\ast \cup v^\ast, -, (u, +)^\ast)\) for all \( u \in \binom{n}{m} \) and \( v \in V \) occurring in \( u \) where \( v^\ast \) is the sub-\( \Sigma \)-hypergraph of \( B_{m,n} \) with the vertex \( v \) and a \( \ast \)-flag at \( v \).

The first three types of reactions applied to a state make sure that the state is sustained. The only changing reactions are of the fourth type. They add a \( \ast \)-labeled twin hyperedge whenever some attachment vertex of a \( \ast \)-labeled hyperedge has a \( \ast \)-flag. In the drawings, a circle represents a vertex and a box a flag. The label is inside the box, and a line from a box to a circle represents the attachment.

The modeling is continued in Section 3.3.

The second example is less interesting from a computational point of view, but serves to illustrate how non-trivial inhibitors work. Consider \( CH_{m,n}^{(2)} \) as background and the following reactions: \( a(e) = (e^\ast, \{v_1, \ldots, v_l\} \subset \hat{e}^\ast, e^\ast) \) for all \( e \in \binom{n}{m} \times \{\ast\} \) with \( attach(e) = v_1 \cdots v_l \) where \( \hat{e} \) is the twin of \( e, e^\ast \) and \( \hat{e}^\ast \) are defined as in Point 1, and \( \{v_1, \ldots, v_l\} \) represents the discrete hypergraph with the attachment vertices of \( e \) as vertices. A reaction \( a(e) \) is enabled on some state \( H \) if \( e \in E_H \) and \( \hat{e} \notin E_H \). In other words, the application of all reactions sustains all \( \ast \)-hyperedges of \( H \) that are not accompanied by their twins.

### 3.3 Interactive Processes

The definition of reaction systems over a category is chosen in such a way that the semantic notion of interactive processes can be carried over directly from the set-based and graph-based cases.

**Definition 2**  
1. Let \( \mathcal{A} = (B, A) \) be a reaction system over \( C \). An interactive process \( \pi = (\gamma, \delta) \) on \( \mathcal{A} \) consists of two sequences of subobjects of \( B \) \( \gamma = c_0, \ldots, c_n \) and \( \delta = d_0, \ldots, d_n \) for some \( n \geq 1 \)
such that \( d_i = \text{res}_{\alpha_{i🇺}}(c_{i-1} \cup d_{i-1}) \) for \( i = 1, \ldots, n \). The sequence \( \gamma \) is called context sequence, the sequence \( \delta \) is called result sequence where \( d_0 \) is called start, and the sequence \( \tau = t_0, \ldots, t_n \) with \( t_i = c_i \cup d_i \) for \( i = 0, \ldots, n \) is called state sequence.

2. \( \pi \) is called context-independent if \( c_i \subseteq d_i \) for \( i = 0, \ldots, n \).

**Remark 2** Consider a context-independent process \( \pi = (c_0, \ldots, c_n, d_0, \ldots, d_n) \).

1. Using point [1b] of Properties [7] in the previous section, \( c_i \subseteq d_i \) for \( i = 0, \ldots, n \) implies \( t_i = c_i \cup d_i = d_i \) meaning that the result sequence and state sequence coincide and that the state sequence describes the whole process determined by its initial state \( t_0 = d_0 \). Therefore, whenever context-independent processes are considered, one can focus on their state sequences.

2. Let \( \tau = t_0, \ldots, t_n \) for some \( n \geq 1 \) be a state sequence. Then \( \tau \) is either repetition-free, i.e., \( t_i \neq t_j \) for all \( i, j \) with \( 0 \leq i < j \leq n \), or there is a smallest pair \( t_i, t_j \) with \( 0 \leq i_0 < j_0 \leq n \) and \( t_{i_0} = t_{j_0} \) such that \( \tau = t_0, \ldots, t_{i_0}, (t_{i_0+1}, \ldots, t_{j_0})^m t_{j_0}, \ldots, t_n \) for some \( m \in \mathbb{N} \) where \( k = i_0 + 1 + m(j_0 - i_0) + 1 \) and \( t_{i_0}, \ldots, t_{j_0} \) is an initial section of \( t_{i_0+1}, \ldots, t_{j_0} \). According to the choice of \( i_0 \) and \( j_0 \), the section \( t_{i_0}, \ldots, t_{j_0-1} \) is repetition-free.

3. Using the pigeonhole principle, the pair \( i_0, j_0 \) exists if \( n - 1 \) is greater than the number of states. Therefore, every state sequence runs into a unique cycle eventually.

### 3.4 An Interactive Process for \( \Sigma \)-Hypergraphs

Let \( H \subseteq CH_{m,n}^{(2)} \) be a sub-\( \Sigma \)-hypergraph with \( * \)-labeled hyperedges only. Let \( i_1, \ldots, i_k \) be a combination of \( k \) elements of \([n]\) for some \( k \in \mathbb{N} \). Then one can consider the interactive process \( \pi(H, i_1 \cdots i_k) = (\gamma(H, i_1 \cdots i_k), \delta(H, i_1 \cdots i_k)) \) with \( \gamma(H, i_1 \cdots i_k) = (i_1 \cdot \ast, \ldots, i_k \cdot \ast).MPT \) and \( H \) as start. Then \( \{i_1, \ldots, i_k\} \) is a \( k \)-vertex-cover of \( H \) if and only if each hyperedge of \( H \) has a twin in the final result. Consequently, to test whether \( H \) is \( k \)-vertex-coverable, one may run the interactive process \( \pi(H, i_1 \cdots i_k) \) for all combinations of \( k \) elements of \([n]\).

**Example 2** Let \( \gamma(B_{3,5}, 2, 4) = 2 \cdot \ast, 4 \cdot \ast).MPT \). The result sequence is

\[
\begin{array}{c}
\text{1} \overset{1}{\longrightarrow} \text{2} \overset{1}{\longrightarrow} \text{3} \\
\text{1} \overset{1}{\longrightarrow} \text{2} \overset{1}{\longrightarrow} \text{3} \\
\text{1} \overset{1}{\longrightarrow} \text{2} \overset{1}{\longrightarrow} \text{3} \\
\text{1} \overset{1}{\longrightarrow} \text{2} \overset{1}{\longrightarrow} \text{3} \\
\end{array}
\]

The lines connecting a box with vertex circle provide the attachment where the numbering establishes its order. In the second and third hypergraph the numbering is omitted to clarify the drawing. \( c_0 \) enables the reaction \((123, *) \cup 2.*, -,(123, +)*)\) and \( c_1 \) enables the reaction \((134, *) \cup 4.*, -,(134, +)*)\) as well as the reaction \((145, *) \cup 4.*, -,(145, +)*)\).

Note that it is also possible to choose both in parallel, e.g., choose \( c'_0 \) to be \( c_0 \cup c_1 = 2 \cdot \ast, 4 \cdot \ast \) and \( c'_1 = MPT \) meaning that the test can be done in one step.
4 Diagram Categories are \( eiu \)-categories

Many categories follow a common building principle, called diagram categories, providing a reservoir of potential example categories over which reaction systems are defined because certain diagram categories turn out to be \( eiu \)-categories if the underlying category is an \( eiu \)-category.

Let \( Scm = (C, A, s: A \to C, t: A \to C) \) be a directed graph (without labeling), called scheme, where the vertices are also called components and the edges arrows. Then \( Scm \) induces the diagram category \( C_{Scm} \) over \( C \). Its objects are graph morphisms \( \delta : Scm \to gr(C) \), where the domain is the scheme \( Scm \) and the codomain is the underlying graph of the category \( C \), i.e., \( gr(C) = (\text{Ob}_C, \sum_{X,Y \in \text{Ob}_C} \text{Mor}_C(X,Y), \delta, \iota) \) with objects of \( C \) as vertices and the disjoint union of all sets of morphisms as set of edges, and \( \delta(f : X \to Y) = X \) and \( \iota(f : X \to Y) = Y \) for all \( f \in \text{Mor}_C(X,Y) \) and all \( X, Y \in \text{Ob}_C \). The objects of \( C_{Scm} \) are called diagrams. Given two diagrams \( \delta, \delta' : Scm \to gr(C) \), a morphism \( g : \delta \to \delta' \) is given by a family of \( C \)-morphisms \( \{g_c : \delta_c(c) \to \delta'_c(c)\}_{c \in C} \) such that \( g_{s(a)} \circ \delta_E(a) = \delta'_E(a) \circ g_{t(a)} \) for all \( a \in A \). This means that the following diagram commutes:

\[
\begin{array}{ccc}
\delta_v(s(a)) & \xrightarrow{\delta_E(a)} & \delta_v(t(a)) \\
\downarrow{g_{s(a)}} & = & \downarrow{g_{t(a)}} \\
\delta'_v(s(a)) & \xrightarrow{\delta'_E(a)} & \delta'_v(t(a))
\end{array}
\]

The composition and the identities are defined componentwise in the category \( C \). The components of \( Scm \) are placeholders for objects, the arrows for morphisms. To avoid an extra handling of labeling and typing functions or such, we also allow fixed components meaning that such a component is instantiated by some fixed object in each diagram and each morphism in a fixed component is always the identity.

Schemes may be drawn in the usual way: Bullets represent components connected by arrows from source bullet to target bullet each. In the case of a fixed component, the bullet is replaced by the associated fixed object.

Often used categories turn out to be diagram categories:

1. The product category \( \text{Sets} \times \text{Sets} = \text{Sets}^{**} \) of ordered pairs of sets.
2. The category \( \Sigma\text{-Sets} = \text{Sets}^{\Sigma \to \Xi} \) of \( \Sigma \)-labeled sets for some alphabet \( \Sigma \).
3. The category \( \text{Maps} = \text{Sets}^{\ast \to \ast} \) of mappings.
4. The category \( \text{Graphs} = \text{Sets}^{\Xi \to \Xi \to \ast} \) of directed (unlabeled) graphs.
5. The category \( \Sigma\text{-Graphs} = \text{Sets}^{\Sigma \to \Xi \to \Xi \to \ast} \) of \( \Sigma \)-graphs for some alphabet \( \Sigma \).
6. The category \( (\Sigma_V, \Sigma_E)\text{-Graphs} = \text{Sets}^{\Sigma_E \to \Xi \to \ast \to \Xi \to \Sigma_V} \) of directed vertex- and edge-labeled graphs.
7. The category \( \text{BipartiteGraphs} = \text{Sets}^{\Xi \to \Xi \to \Xi} \) of bipartite directed graphs. Let \( G = (V_1, V_2, E_1, E_2, s_1 : E_1 \to V_1, s_2 : E_2 \to V_2, t_1 : E_1 \to V_2, t_2 : E_2 \to V_1) \) be an object. There are two sets of vertices and two sets of edges. Edges have sources in \( V_1 \) and targets in \( V_2 \) or the other way round.
8. The category \( \text{3-Hypergraphs} = \text{Sets}^{\Xi \to \Xi \to \Xi} \) of hypergraphs with hyperedges of type 3. Let the three arrows be \( l, r, t \) respectively, and let \( H = (V, E, (l_H, r_H, t_H)) \) be an object. Then each \( e \in E \) is attached to a “left”, a “right”, and a “top” vertex so that \( e \) can be seen as a triangle.
9. The category $4\text{-Hypergraphs} = \text{Sets} \otimes^* \theta$ of hypergraphs with hyperedges of type 4. Let the four arrows be north, east, south, west, then the hyperedges are of type 4 and can be seen as “cells” with “tentacles” to the respective directions.

10. An interesting example where the underlying category is not $\text{Sets}$ is the category $\text{Graphs} \otimes^* \rightarrow \Sigma$ of $\Sigma$-typed graphs for some type graph $\Sigma$. They are often used in the area of graph transformation as a well-working generalization of labeled graphs. A $\Sigma$-typed graph is represented by a pair $(G, t)$, where $G$ is a directed (unlabeled) graph and $t : G \rightarrow \Sigma$ is a graph morphism specifying the structure of $G$. A $\Sigma$-type-graph morphism $f : (G_1, t_1) \rightarrow (G_2, t_2)$ is a graph morphism $f_G : G_1 \rightarrow G_2$ such that $t_2 \circ f_G = t_1$.

Indeed, $\Sigma\text{-Graphs}$ is in a one-to-one correspondence to $\text{Graphs} \otimes^* \rightarrow \Sigma$ where $\Sigma$ has a single vertex and, for each $x \in \Sigma$, an $x$-labeled loop at the vertex. Similarly, $(\Sigma_V, \Sigma_E)\text{-Graphs}$ is in a one-to-one correspondence to $\text{Graphs} \otimes^* \rightarrow (\Sigma_V, \Sigma_E)$ where $\Sigma(V, E) = (\Sigma_V, \Sigma_V \times \Sigma_E \times \Sigma_V, pr_1, pr_3)$ with the first and third projections $pr_1$ and $pr_3$ as source and target mappings respectively.

Concerning diagram categories, it may be noted that categories of the form $C \otimes^* \rightarrow X$ for some fixed object $X$ are also called slice categories. Two of our examples, $\Sigma\text{-Sets} = \text{Sets} \otimes^* \Sigma$ and $\Sigma\text{-Graphs} = \text{Graphs} \otimes^* \rightarrow \Sigma$ are slice categories.

The main result of this section is that diagram categories are eiu-categories if the underlying category is an eiu-category and the fixed components of the considered schemes have no out-going arrows.

**Theorem 1** Let $C$ be an eiu-category and $Scm$ be a scheme where no fixed component is a source of an arrow. Then $C^{Scm}$ is an eiu-category.

**Proof** It is known that limits and colimits in diagram categories without fixed components can be constructed componentwise by limits and colimits of the underlying category. It is also known that limits and colimits in slice categories (with a scheme of the form $\bullet \rightarrow \Sigma$) can be constructed by the limits and colimits of the free component in the underlying category. The statement can be proved for diagram categories with fixed components in the same way by combining the arguments for the two known cases.

**Remark 3** The proof of the theorem is not only analogous to the proof for diagram categories without fixed components and slice categories, but it also may be that a diagram category with fixed components is isomorphic to a slice category with an underlying diagram category without fixed components so that the theorem follows directly from the known results.

If one allows to replace a bullet in a scheme $Scm$ by a $*$ and uses it in $\text{Sets}^{Scm}$ in such a way that the $*$ is not replaced by a set $X$, but by the set of strings $X^*$ over $X$, then even the category of $\Sigma\text{-Hypergraphs}$ can be obtained as a diagram category: $\Sigma\text{-Hypergraphs} = \text{Sets}^{\Sigma \rightarrow \bullet \rightarrow *}$ . We know already that $\Sigma\text{-Hypergraphs}$ is an eiu-category. But it is open whether Theorem 1 holds using this kind of schemes.

It is not difficult to see that all our explicit examples listed above and many like these meet the assumptions of the theorem.

5 Towards a Category of Reaction Systems over a Category

So far, everything we have discussed concerns reaction systems over categories. But there are more ways to bring reaction systems and category theory together. Whenever one has a class of entities, one
may try to use them as objects of a category by choosing suitable morphisms. Therefore, one may ask how reaction systems over a category may be provided with a meaningful notion of morphisms.

In this section, we show that, given a reaction system $\mathcal{A} = (B, A)$ over $C$, a monomorphism $f : B \to B'$ induces a reaction system $f(\mathcal{A})$ by composing all the components of reactions with $f$. This observation motivates us to consider such a morphism as morphism from $\mathcal{A}$ to $\mathcal{A}' = (B', A')$ provided that $f(\mathcal{A}) \subseteq A'$.

**Theorem 2** Given a reaction system $\mathcal{A} = (B, A)$ and a monomorphism $f : B \to B'$. Then $f$ induces a reaction system $f(\mathcal{A}) = (B', f(A))$ where $f(A) = \{f(a) \mid a \in A\}$ and $f(a) = (f \circ r : R \to B', (f \circ i : I \to B', i_0 : I_0 \to I), f \circ p : P \to B')$ for $a = (r : R \to B, (i : I \to B, i_0 : I_0 \to I), p : P \to B)$.

$f(\mathcal{A})$ has the following properties.

1. $en_a(t)$ on a state $t : T \to B$ if and only if $en_{f(a)}(f \circ t)$,
2. $f \circ res_a(t) = res_{f(a)}(f \circ t)$,
3. $f \circ res_{\mathcal{A}}(t) = res_{f(\mathcal{A})}(f \circ t)$.

The following diagram shows $a$ and $f(a)$.

![Diagram](image)

The proof uses the following lemma.

**Lemma 1** 1. Let $p : P \to B, p' : P \to B$ and $f : B \to B'$ be monomorphisms. Let $L = (PB, p' : PB \to P, p : PB \to \overline{P})$ be a triple of an object $PB$ and two monomorphisms $p'$ and $\overline{p'}$. Then $L$ is a pullback of $p$ and $\overline{p}$ if and only if $L$ is a pullback of $f \circ p$ and $f \circ \overline{p}$.

2. Let $S$ be a set of subobjects of $B$ and $f : B \to B'$ be a monomorphism. Then $f \circ \text{union}(S) = \text{union}(\{f \circ p \mid p \in S\})$.

**Proof** Point 1 follows immediately from the observation that a monomorphism is a limit and that limits compose.

2. Using Point 1, one get $PB(S) = PB(\{f \circ p \mid p \in S\})$ so that $\text{UNION}(S) \cong \text{UNION}(\{f \circ p \mid p \in S\})$ and $f \circ \text{union}(S) = \text{union}(\{f \circ p \mid p \in S\})$ as subobjects.
The situation of Point 1 of the lemma is depicted in the following diagram.

And the situation of Point 2 where \( S = \{p_1, p_2, p_3\} \) is depicted in the following diagram.

**Proof** of Theorem 2. 1. Given a reaction \( a = (r, (i, i_0), p) \) and a state \( t \) in \( \mathcal{A} \), \( \text{en}_a(t) \) means \( r \subseteq t \) and \( t \cap i \subseteq i \circ i_0 \). By definition, there are monomorphisms \( s \) and \( s' \) with \( r = t \circ s \) and \( t \cap i = i \circ i_0 \circ s' \). This implies \( f \circ r = f \circ t \circ s \) and by Point 1 of Lemma 1 also \( f \circ r \subseteq f \circ t \circ s \) and \( (f \circ t) \cap (f \circ i) = f \circ (t \cap i) = f \circ i \circ i_0 \circ s' \). This means \( (f \circ t) \cap (f \circ i) \subseteq f \circ i \circ i_0 \circ s' \) and, therefore, \( \text{en}_{f(a)}(f \circ t) \).

Conversely, \( \text{en}_{f(a)}(f \circ t) \) means \( f \circ r \subseteq f \circ t \circ s \) and \( (f \circ t) \cap (f \circ i) \subseteq f \circ i \circ i_0 \circ s' \). By definition, there are monomorphisms \( s \) and \( s' \) with \( f \circ r = f \circ t \circ s \) and \( (f \circ t) \cap (f \circ i) = f \circ i \circ i_0 \circ s' \). By the Point 1 of Lemma 1 one has \( f \circ (t \cap i) = (f \circ t) \cap (f \circ i) \) so that the monomorphisms of \( f \) yields \( r = t \circ s \) and \( t \cap i = i \circ i_0 \circ s' \). This means \( r \subseteq t \) and \( t \cap i \subseteq i \circ i_0 \circ s' \) and, therefore, \( \text{en}_a(t) \).

2. According to Point 1, there are two cases to consider using the definition of results: \( f \circ \text{res}_a(t) = f \circ p = \text{res}_{f(a)}(f \circ t) \) provided that \( a \) is enabled on \( t \) and \( f(a) \) on \( f \circ t \); and \( f \circ \text{res}_a(t) = f \circ \text{empty}_{B'} = \text{res}_{f(a)}(f \circ t) \) otherwise.

3. Using the definition of results of reaction systems and sets of reactions as well as Points 1 and 2 of Lemma 1 one gets as stated: \( f \circ \text{res}_{A'}(t) = f \circ \text{res}_A(t) = f \circ \text{union}(\{\text{res}_a(t) \mid a \in A\}) = \text{union}(\{f \circ \text{res}_a(t) \mid a \in A\}) = \text{res}_{f(A)}(f \circ t) = \text{res}_{f(A')}(f \circ t) \).
Using Point 3 of the theorem and Point 1 of Properties 1 one gets the following result.

**Corollary 1** Let $\mathcal{A} = (B, A)$ and $\mathcal{A}' = (B', A')$ be two reaction systems over $C$ with $f(A) \subseteq A'$ for some monomorphism $f: B \to B'$. Then $f \circ \text{res}_{\mathcal{A}}(t) \subseteq \text{res}_{\mathcal{A}'}(f \circ t)$ for all states $t: T \to B$.

This motivates to define the category $\text{RS}(C)$.

**Definition 3** Let $C$ be an $eiu$-category.

1. The category $\text{RS}(C)$ is defined as follows. Its objects are reactions systems over $C$. Given two reaction systems $\mathcal{A} = (B, A)$ and $\mathcal{A}' = (B', A')$ over $C$, a morphism $f: \mathcal{A} \to \mathcal{A}'$ is given by monomorphisms $f: B \to B'$ provided that $f(A) \subseteq A'$. Compositions and identities are given by the underlying morphisms.

2. If $f \circ \text{res}_{\mathcal{A}}(t) = \text{res}_{\mathcal{A}'}(f \circ t)$ for all states $t: T \to B$, then $f: \mathcal{A} \to \mathcal{A}'$ is called strong.

The definition of composition and identities is meaningful as, for reaction systems $\mathcal{A} = (B, A)$, $\mathcal{A}' = (B', A')$ and $\mathcal{A}'' = (B'', A'')$ and for morphisms $f: \mathcal{A} \to \mathcal{A}'$ and $g: \mathcal{A}' \to \mathcal{A}''$, $(g \circ f)(A) = g(f(A)) \subseteq g(A') \subseteq A''$ and $1_A = A$.

**Example 3** Consider the two reaction systems over $\Sigma$-Hypergraphs $\mathcal{A}_{m,n}, \mathcal{A}_{m',n'}$ with $m \leq m'$ and $n \leq n'$ as defined in Section 2.2.

The inclusion of $B_{m,n}$ into $B_{m',n'}$ induces a morphism from $\mathcal{A}_{m,n}$ to $\mathcal{A}_{m',n'}$ as $A_{m,n} \subseteq A_{m',n'}$. This morphism is strong as one can see as follows. Let $T$ be a sub-$\Sigma$-hypergraph of $B_{m,n}$ representing a state of $\mathcal{A}_{m,n}$. Then $T$ represents also a state of $\mathcal{A}_{m',n'}$. According to Corollary 1 we know that $\text{res}_{\mathcal{A}_{m,n}}(T) \subseteq \text{res}_{\mathcal{A}_{m',n'}}(T)$. Let now $(R', \ldots, P')$ be a reaction in $\mathcal{A}_{m',n'}$ that is not in $\mathcal{A}_{m,n}$. As $B_{m,n}$ is complete with respect to hyperedges including flags, $R'$ and $P'$ must contain a vertex $k' > n$. Consequently, $R' \not\subseteq T$ such that the reaction is not enabled and none of those can contribute to $\text{res}_{\mathcal{A}_{m,n}}(T)$ meaning that $\text{res}_{\mathcal{A}_{m,n}}(T) = \text{res}_{\mathcal{A}_{m',n'}}(T)$. Summarizing, the family $\{\mathcal{A}_{m,n}\}_{m,n \in \mathbb{N}}$ forms a two-dimensional grid connected by strong morphisms along growing indices. This is interesting with respect to the vertex-coverability of hypergraphs. Each hypergraph can be transformed into a sub-$\Sigma$-hypergraph of $B_{m,n}$ for some $m, n$ by numbering the vertices and removing labels, multiples of hyperedges and multiples of vertex attachments within a hyperedge in such a way that its vertex-coverability is preserved. Then the grid of strong morphisms makes sure that the result of the vertex-coverability test is independent of the choice of the $B_{m,n}$ as long as the transformation works. In this sense, the family $\{\mathcal{A}_{m,n}\}_{m,n \in \mathbb{N}}$ models a vertex-coverability test for all hypergraphs.

6 Conclusion

In this paper, we have proposed a categorical framework for the modeling of reaction systems. We have provided appropriate categorical notions including finite objects, subobjects, subobject inclusions, empty subobjects, intersections and unions of subobjects that allow the definition of reaction systems over $eiu$-categories and their interactive-process semantics in a quite similar way to the known set- and graph-based reaction systems. Moreover, we have shown that many categories meet the categorical requirements so that many structures become available on which reaction systems may be based on. This includes, in particular, quite a variety of graphs, hypergraphs, and other graph-like structures. But we have only done the very first steps into a categorical approach. To shine more light on the significance of the framework, the investigation should be continued including the following topics.
1. As pointed out at the end of Section 2, it would be interesting to clarify the relationship between eiu-categories and the well-studied adhesive categories that are successfully applied in the area of graph transformation in various variants (cf., e.g., [3, 7, 4, 2, 8]).

2. In Section 4, we have shown that diagram categories provide a reservoir of eiu-categories. Another way to find appropriate categories is the restriction of eiu-categories to subcategories. For example, if one restricts the category $\Sigma$-Graphs to simple graphs, then this category is closed under empty subobjects, intersections and unions so that this category inherits all reaction systems over $\Sigma$-Graphs if the background graph is simple. How do general restriction principles look like that yield such subcategories?

3. In Section 5, we have shown that monomorphisms on the background objects provide suitable morphisms between reaction systems over a category. What about further possibilities?

4. Another direction of research of this kind may be to consider functors. For instance, the usual embedding of $\Sigma$-graphs into $\Sigma$-hypergraphs induces such a functor. The other way round, the usual transformation of a hypergraph into a graph can be extended to morphisms. The question is which properties of a functor $F : C \to C'$ are sufficient such that a reaction system $\mathcal{A}$ over $C$ is translated into a reaction system $F(\mathcal{A})$ over $C'$. Whenever this works, one can compare reaction systems over different categories.

Acknowledgment We are grateful to Nicolas Behr, Andrea Corradini, Reiko Heckel, Berthold Hoffmann, Jens Kosiol, Sabine Kuske and Gabriele Taenzer for their valuable hints. We are particularly grateful to Grzegorz Rozenberg who encouraged us to investigate graph surfing in reaction systems from a categorical point of view. Last but not least, we would like to thank the anonymous reviewers for their helpful comments and hints that led to some improvements.
