Abstract

This paper describes the University of Maryland’s submission to the Duolingo Shared Task on Simultaneous Translation And Paraphrase for Language Education (STAPLE). Unlike the standard machine translation task, STAPLE requires generating a set of outputs for a given input sequence, aiming to cover the space of translations produced by language learners. We adapt neural machine translation models to this requirement by (a) generating \( n \)-best translation hypotheses from a model fine-tuned on learner translations, oversampled to reflect the distribution of learner responses, and (b) filtering hypotheses using a feature-rich binary classifier that directly optimizes a close approximation of the official evaluation metric. Combination of systems that use these two strategies achieves F1 scores of 53.9% and 52.5% on Vietnamese and Portuguese, respectively ranking 2nd and 4th on the leaderboard.

1 Introduction

While machine translation (MT) typically produces a single output for each input, scoring and generation for second language learning applications might benefit from systems whose outputs better capture the diversity of translations produced by language learners. The Duolingo Simultaneous Translation And Paraphrase for Language Education (STAPLE) shared task (Mayhew et al., 2020) provides a framework for developing and testing such systems, grounded in real translations produced by English learners into five native languages (Portuguese, Vietnamese, Hungarian, Japanese, Korean). In this task, given an English sentence prompt, systems are asked to produce a set of translations for that prompt, and are scored based on how well their outputs cover human-curated acceptable translations, weighted by the likelihood that an English learner would respond with each translation (Table 1).

| Prompt | Output |
|--------|--------|
| is my explanation clear? | minha explicação está clara? |
| | minha explicação é clara? |
| | a minha explicação está clara? |
| | está clara minha explicação? |
| | minha explicação é clara? |

Table 1: STAPLE data: given a prompt in English, translation alternatives are weighted according to Learner Response Frequency (LRF)

While the multiple translations can be viewed as paraphrases, we propose to address the STAPLE task primarily as a MT task to better understand the strengths and weaknesses of neural MT architectures for generating multiple learner-relevant translations. Given a Transformer model for the language pair of interest, we use beam search to generate \( n \)-best translation candidates. However, since \( n \)-best lists are known to lack diversity, we propose to generate hypotheses that better match the requirements of the STAPLE task via:

1. **Frequency-Aware \( n \)-Best Lists**: We encourage hypotheses to reflect the diversity and frequency of learner responses by fine-tuning models on STAPLE data, oversampling translation options to reflect learner preferences.

2. **Hypothesis Filtering**: We filter the resulting \( n \)-best lists using a binary classifier which identifies good translations that are likely to be produced by a learner.

Controlled experiments and analysis show the benefits of both strategies. Our final submission which includes both techniques achieves F1 scores of 53.9% and 52.5% for en-vi and en-pt respec-
tively, reaching a rank of 2nd and 4th on the leader-
board, only 2 points below the top scoring sys-
tem. For completeness, we also submitted systems
for the remaining language pairs using Frequency-
Aware n-best lists: our system ranked 2nd for
Japanese and 3rd for Korean and Hungarian.

2 Background

Unlike in the STAPLE task, recent attempts at gen-
erating multiple translations for a single source
have targeted output variability along specific
stylistic dimensions (Sennrich et al., 2016b; Rab-
inovich et al., 2016; Niu et al., 2018; Agrawal and
Carpuat, 2019) or produce diverse outputs without
a specific use case (Kikuchi et al., 2016; Shu et al.,
2019). The techniques used can be divided in three
categories: (a) constrain the decoding process to
generate diverse candidates (Li and Jurafsky, 2016;
Li et al., 2015; Cho, 2016); (b) optimize via a di-
versity promoting loss function (Li et al., 2015); (c)
expose the model to different translation candidates
with side-constraints (Rabinovich et al., 2016; Sen-
rrich et al., 2016a; Niu et al., 2018; Agrawal and
Carpuat, 2019; Shu et al., 2019) or without (Shen
et al., 2019). Since it is unclear what dimensions
of variations are captured in the STAPLE trans-
lation, we focus instead on improving n-best lists
generated by a standard neural MT model.

Source texts with multiple references have mostly
been used to evaluate rather than train MT
systems (Papineni et al., 2002; Banerjee and Lavie,
2005; Qin and Specia, 2015). Evaluation sets with
4 or 5 references have been converted to single-
reference training samples (Zheng et al., 2018) to
obtain translation training samples. We propose to tailor
MT to the STAPLE task by fine-tuning models on
LRF-weighted multi-reference samples to obtain
more diverse translations and a ranking that better
reflect learner preferences.

Given the STAPLE data for a language pair,
where the i-th training example, (e_i, F_i, W_i) in-
cludes a source sentence in English, a reference set
F_i = \{f_i^1, f_i^2, ..., f_i^K\} of K translations and corre-
sponding LRF weights W_i = \{w_i^1, w_i^2, ..., w_i^K\},
we create MT training samples by copying the
translation pair (e_i, f_i^j), w_i^j \times O times.1 Given
model parameters \(\theta\), this yields a weighted cross-
entropy loss:

\[\mathcal{L}_{trf}(\theta) = \sum_{i=1}^{M} \sum_{j=1}^{K} (w_i^j \times O) \log Pr(f_i^j|e_i; \theta) \]  

3.2 Hypothesis Filtering as Binary
Classification

Even when informed by STAPLE data and LRF
scores, n-best lists might include translations that
are not in the reference set, due to translation errors
or selecting paraphrases that do not match language
learners’ preferences. We design a binary classi-
fier that further filters the n-best lists by predicting
for each hypothesis whether or not it should be in-
cluded in the final set. This lets us define features
based on the complete prompt and hypothesis se-
quence pairs, while the MT model generates the
hypothesis incrementally.

Let \(D = \{(e_i, \hat{f}_i^1, \hat{f}_i^2, ..., \hat{f}_i^N)\}_i^M\) represent the
n-best list generated via beam search for all the
source prompts in the training dataset: \(e_i\) corre-
sponds to the i-th source prompt and \(\hat{f}_i^j\) corre-
sponds to the j-th candidate hypothesis extracted
via beam search. \(x_i^j\) represents the feature vector
extracted from the source \((e_i)\) and \(y_i^j\) is a binary label indicative
of whether the candidate hypothesis, \(\hat{f}_i^j\), is found
in the gold standard data. The classification model
\(f : X \rightarrow \mathbb{R}\) maps the feature vector to a real value,
where, f is a two-layer Neural Network (NN) to
enable learning feature combinations.

Features We aim to capture the quality of a
source-hypothesis pair using multiple sentence-
level features:

- Length features \(|\hat{f}_i^j|, |e_i|, |\hat{f}_i^j|, |\hat{f}_i^j|\) might indicate
  mismatches between source and target content.
- Word alignment features have proved useful
  to identify semantic divergences in bitext

\[\text{We set } O = 1000 \text{ in practice.}\]
(Munteanu and Marcu, 2005; Vyas et al., 2018). We use the Forward and Reverse Alignment score, the count of unaligned words for source and target, and the top three largest fertilities for source and target.

- Scores from various MT models as often done when reranking n-best lists (Cherry and Foster, 2012; Neubig et al., 2015; Hassan et al., 2018) including a left-to-right model, a right-to-left model, and a target-to-source model, which provide different views of the example and might better estimate the adequacy of the translation than the original MT model score.

- Target 5-gram language model score to estimate the fluency of the hypothesis.

**Loss** We optimize a Soft Macro-F1 objective (Hsieh et al., 2018) function to approximate the official evaluation metric. The true positive (tp), false positive (fp), and true negative (tn) rate for each source prompt $e_i$ are estimated as:

\[
\begin{align*}
    tp_{e_i} &= \sum_{t=1}^{N} \hat{y}_i \times y_i \\
    fp_{e_i} &= \sum_{t=1}^{N} \hat{y}_i \times (1 - y_i) \\
    tn_{e_i} &= \sum_{t=1}^{N} (1 - \hat{y}_i) \times y_i
\end{align*}
\]

Then, the precision, recall, F1 for a source $e_i$, and the loss are defined as:

\[
\begin{align*}
    P_{e_i} &= \frac{tp_{e_i}}{tp_{e_i} + fp_{e_i} + \epsilon} \\
    R_{e_i} &= \frac{tp_{e_i}}{tp_{e_i} + fn_{e_i} + \epsilon} \\
    F1_{\text{Macro}_e} &= \frac{2 \times P_{e_i} \times R_{e_i}}{P_{e_i} + R_{e_i} + \epsilon} \\
    \text{Loss} &= \sum_{i=1}^{M} (1 - F1_{\text{Macro}_e_i})
\end{align*}
\]

4 Experiment Settings

4.1 Data

**STAPLE Data** The shared task provides English source prompts, associated with high-coverage sets of plausible translations in five other languages. These translations are weighted and ranked according to LRF scores indicating which translations are more likely. About 3000 prompts per language are available (see Table 2 for details) and the number of reference translations available per prompt vary across languages (mean: 174.2, variance: 116). Figure 1 illustrates the differences in LRF distributions across languages: for languages with many references per prompt (e.g. en-ja, en-ko), the gap between the top-1 and the mean LRF value is small, indicating an almost uniform distribution. Average top-1 LRF scores also vary across languages (e.g. en-vi: 0.25, en-ja: 0.05) depending upon the number of references available per prompt.

For system development, we divide the STAPLE dataset into train, development and test datasets using 72%, 8%, and 20% of source prompts respectively. We refer to these subsets as STAPLE\_train, internal dev and internal test. Note that the last two differ from the official blind development and test sets available to participants on codalab.

**Other Bitexts** We use bitext from OpenSubtitles (Tiedemann, 2012) and Tatoeba (Tiedemann, 2012) as described in Table 3. The Tatoeba corpus provides multiple reference translations for some sources (with 2 translation per source on average), but unlike in the STAPLE data, these translations are not weighted by frequency of usage.

**Preprocessing** All datasets are pre-processed using Moses tools for normalization, tokenization and lowercasing. We further segment tokens into subwords using a joint source-target Byte Pair Encoding (Sennrich et al., 2016c) model with 32,000

Figure 1: Average of the top-1, top-5, mean and median LRF values across source prompts: the LRF distribution is more uniform for languages with many more references per prompt (e.g. en-ja).
Table 2: STAPLE data statistics: segments in our train/dev/test split, overall vocabulary statistics and average translations per source prompt (T/S).

| Language | OpenSubtitles | Tatoeba |
|----------|---------------|---------|
| en-pt    | 47.2M         | 196K    |
| en-vi    | 3M            | 5.3K    |
| en-ja    | 1.8M          | 200K    |
| en-ko    | 1.2M          | 2.7K    |
| en-hu    | 34.5M         | 102K    |

Table 3: Additional bitext used for training and fine-tuning MT models

4.2 MT configurations

Model Architecture We use the Transformer model implemented in the Sockeye toolkit\(^4\) as a baseline MT system. Both encoder and decoder are 6-layer Transformer models with model size of 1,024, feed-forward network size of 4,096, and 16 attention heads. We adopt label smoothing and weight tying. We tie the output weight matrix with the target embeddings. We use Adam optimizer with initial learning rate of 0.0002.

Experimental Conditions We train several models with the above configuration:

- **OpenSubs** a baseline model trained and validated on the OpenSubtitles bitext.
- **Unweighted** builds on the baseline by fine-tuning on multi-reference samples including the Tatoeba bitext and STAPLE train. We create one training sample per source-reference pair, and the resulting samples are not weighted. We use the internal dev set (1-best reference only) as a validation set.

- **Frequency-Aware** is fine-tuned as the unweighted model except that STAPLE train is oversampled as described in § 3.1.

We generate \(n\)-best list of translations for various models by running beam search with a beam size corresponding to the desired \(n\).

4.3 Filtering configurations

Classifier The 2-layer feed-forward NN has 5 hidden units and 2 output units. It is trained with the Adam optimizer with an initial learning rate of 0.001 and runs for 2000 epochs on the internal dev set. The best model is selected based on internal test set performance. We consider two losses: the soft macro F1 loss which approximates the official evaluation metric (§ 3.2) and the standard cross-entropy loss as a baseline.

Reranking Baseline We compare our NN based classifier with a standard MT \(n\)-best list reranker trained on the internal dev set. We use the \(n\)-best batch MIRA ranker (Cherry and Foster, 2012) included in Moses. A threshold to filter candidates in the reranked list is selected by maximizing the Weighted Macro F1 on the internal dev dataset.

Features We use eflomal\(^5\) trained on the OpenSubtitles dataset to obtain word alignment between source and translation hypotheses. The language model is trained with the kenlm (Heafield, 2011) toolkit with default hyper-parameters\(^6\) on the target side of the Opensubtitles and the STAPLE dataset. The Right-to-left and Target-to-source MT models were trained on OpenSubtitles (same configuration as in § 4.2).

\(^3\)https://github.com/neubig/kytea
\(^4\)https://github.com/awslabs/sockeye
\(^5\)https://github.com/robertostling/eflomal
\(^6\)https://github.com/kpu/kenlm
5 Evaluation

We evaluate the lowercased detokenized output of the systems on our internal test dataset using:

**Weighted Macro F1** This is the official scoring metric which quantifies how the set of system outputs covers the human-curated acceptable translations, weighted by the LRF of each translation. It is defined as the harmonic mean of unweighted precision (P) and weighted recall (WR) calculated for each prompt $e_i$, and averaged over all the prompts in the corpus. Specifically, using the same notation as introduced in §3.1, for each translation $T_i$ generated by the MT model, we have:

\[
\begin{align*}
WTP_{e_i} &= \sum_{t \in T_i} \sum_{f_j^i \in F_i} 1[ t = f_j^i ] w_j^i \\
WFN_{e_i} &= \sum_{f_j^i \notin T_i} w_j^i \\
WR_{e_i} &= \frac{WTP_{e_i}}{WTP_{e_i} + WFN_{e_i}}
\end{align*}
\]

The weighted Macro F1 (WMF1) is then given by:

\[
WMF1_{e_i} = \frac{2 \times P_{e_i} \times WR_{e_i}}{P_{e_i} + WR_{e_i}}
\]

\[
WMF1 = \frac{1}{M} \sum_{i=1}^{M} WMF1_{e_i}
\]

**BLEU@1** We also report the translation quality of the 1-best neural MT output compared against the highest LRF reference translation using the standard BLEU metric (Papineni et al., 2002).

6 Experiment Results

6.1 Impact of Frequency-Aware Fine-Tuning

Table 4 summarizes the evaluation of n-best lists obtained with our neural MT systems.

**Baselines** We confirm that the neural MT configuration is sound by comparing our neural MT baseline to the provided AWS system. Our baseline (“OpenSubs”) improves the BLEU@1 score by 2 points for en-pt, and remains 6 points lower for en-vi, as can be expected given the smaller size of the OpenSubtitles training set. However, the “OpenSubs” n-best lists improve over the AWS baseline according to the official task metric (WMF1), establishing that this system is a good starting point for fine-tuning.

**Fine-Tuning** The Frequency-Aware n-best hypotheses consistently yield the best Weighted Recall and Weighted Macro-F1 scores for all languages. The improvement in recall and therefore F1 score is largest for en-ja and en-ko which have larger translation reference sets (Table 4). Frequency-Aware oversampling also improves precision over the Unweighted model for all but one language (en-pt). The impact on the auxiliary BLEU@1 metric is less consistent: the Frequency-Aware system achieves the best BLEU@1 in 3 out of 5 languages, but outperforms the OpenSubs baseline in 4 out of 5. BLEU@1 drops when fine-tuning on all the samples without weighting (Unweighted) which we attribute to the increased uncertainty during training as the model is exposed to many different translations for the same source English text.

Overall, these results show the benefits of fine-tuning on task-relevant data and shows that incorporating LRF weights via oversampling improves the ranking of n-best hypotheses. This is further illustrated in Table 5, which shows the top 10 Vietnamese translations for two randomly sampled source prompts: the Frequency-Aware n-best list yields Weighted Recall of 81% at a Precision of 60% and 76% at a Precision of 100% for the two source prompts respectively, illustrating that the model generates high-quality candidates that cover reference translations well, but not perfectly.

**N-Best List Quality** How well do n-best translations cover the space of reference learner translations? Figure 2 shows the impact of increasing the decoding beam (and resulting n-best list size) from 10 to 500 for the Frequency-Aware model. For en-pt, while weighted recall increases up to 66%, the drop in precision hurts the weighted F1 score. The oracle F1 score, which represents the Weighted Macro F1 at a Precision of 100%, also increases gradually, reaching a score of 76%. This suggests that the raw n-best lists contain many useful translation candidates but need to be filtered down to better match translations preferred by language learners.

6.2 Impact of Hypothesis Filtering

Due to time constraints, we explore the impact of hypothesis filtering only for en-pt and en-vi.

**Filtering** consistently improves Precision and Weighted Macro F1 (Table 6). The binary classifier that optimizes Soft Macro-F1 performs best,
as the loss leads to a better balance between Precision and Weighted Recall than cross-entropy. The classifier outperforms the MIRA reranker. Since the reranker is trained to maximize BLEU@1, it tends to prefer candidates that are lexically similar to the top reference translation and misses some of the more diverse learner translations. This confirms the benefits of framing the selection of candidate hypothesis as binary classification.

**Ablation Experiments** show that the MT scores are the most useful of the features used, as they capture not only the generation probability of a candidate hypothesis but estimate adequacy via the Target-to-source neural MT model (Table 8). Length features help precision but not recall, while the alignment and language model scores have little impact overall. This suggests that the classifier could benefit from improved feature design and selection in future work.

### 6.3 Analysis of Translation Diversity

How diverse are the translations returned by various system configurations? Following Zhang et al. (2018), we quantify diversity using the entropy of $k$-gram distributions within a translation set:

$$\text{Ent}_k(V) = -\frac{1}{\sum_w F(w)} \sum_{w \in V} F(w) \log \frac{F(w)}{\sum_w F(w)}$$

where $V$ is the set of all $k$-grams that appear in the translation set, and $F(w)$ denotes the frequency of $w$ in the translations. The higher the Ent-$k$ score, the greater the diversity.

Fine-tuned models improve the diversity of 10-best lists compared to the “OpenSubs” baseline for both en-vi and en-pt (Table 9). Overall filtering bridges 40% and 25% of the gap between baseline and reference learner translations for en-pt and en-vi respectively.

### 6.4 System Combinations

A manual examination of translation sets returned by different models suggest that they make complementary errors. We therefore consider combining system outputs by taking the union of the set of translations they return. We evaluate the following combinations (Table 7):

- C1 Frequency-aware (10-best) + Unweighted (10-best)

Table 4: Frequency-Aware systems outperform both OpenSubs and Unweighted models for all languages. The size of the $n$-best list for each model was selected based on the WMF1 score on the internal test set.
Figure 2: Increasing the size of \( n \)-best list with the Frequency-Aware system improves the coverage of learner translations for en-pt and en-vi. Oracle F1 is the Weighted Macro F1 at a Precision of 100% and represents the upper bound on WMF1 that can be achieved for a given \( n \)-best list.

### Table 5: Frequency-Aware 10-best Vietnamese output for two randomly selected English prompts. LRF values are given for translations found in the reference set.

| Input: We live near the border. | LRF |
|---------------------------------|-----|
| chúng tôi sống gần biên giới.    | 0.250 |
| chúng tôi sống ở gần biên giới.  | 0.053 |
| chúng tôi sống gần đường biên giới. | 0.267 |
| chúng tôi sống bên cạnh biên giới. | 0.018 |
| chúng ta sống gần biên giới.     | 0.013 |
| chúng tôi sống cạnh biên giới.    | 0.061 |
| chúng tôi sống ở cạnh biên giới.  | 0.004 |
| chúng ta sống ở gần biên giới.   | 0.004 |

Precision: 100%, Weighted Recall: 76%

| Input: My family lives in the south. | LRF |
|-------------------------------------|-----|
| gia đình tôi sống ở miền nam.        | 0.285 |
| gia đình của tôi sống ở miền nam.    | 0.134 |
| gia đình tôi sống ở phường nam.     | 0.061 |
| gia đình tôi sống ở phía nam.        | 0.019 |
| gia đình của tôi sống ở phía nam.    | 0.208 |
| nhà của tôi sống ở miền nam.        | - |
| nhà tôi sống ở miền nam.            | - |
| nhà của tôi sống ở phường nam.     | - |
| gia đình tôi sống ở nam.            | - |

Precision: 60%, Weighted Recall: 81%

For en-pt and en-vi, it helps to combine higher precision unfiltered 10-best lists, and higher recall filtered 50-best lists. For en-pt, the union of all outputs (C4) performs best overall. Recall increases when combining the Frequency-Aware and the Unweighted model (C1) compared to individual lists (Unweighted: +1.6, Frequency-Aware: +2) without compromising Precision. Similar trends are observed when adding the filtered 50-best list to unfiltered 10-best lists (C2: +2.2, C3: +4.8).

For en-vi, a different combination (C2) yields the best result, perhaps due to the smaller set of reference translations per source prompt (en-vi: 56, en-pt: 131) and high Precision of the “Unweighted” model for en-pt.

### 7 Submitted Systems

We tested our systems on the official blind development set to select the best performing models for final evaluation on the test set. For Portuguese and Vietnamese, our official submissions include frequency-aware hypothesis generation and hypothesis filtering:

- **en-vi** C2: Frequency-aware (10-best) + Frequency-aware (filtered 50-best)
- **C2** Frequency-aware (10-best) + Frequency-aware (filtered 50-best)
- **C3** Unweighted (10-best) + Unweighted (filtered 50-best)
- **C4** Union of all of the above.

For en-pt and en-vi, it helps to combine higher precision unfiltered 10-best lists, and higher recall filtered 50-best lists. For en-pt, the union of all outputs (C4) performs best overall. Recall increases when combining the Frequency-Aware and the Unweighted model (C1) compared to individual lists (Unweighted: +1.6, Frequency-Aware: +2) without compromising Precision. Similar trends are observed when adding the filtered 50-best list to unfiltered 10-best lists (C2: +2.2, C3: +4.8).

For en-vi, a different combination (C2) yields the best result, perhaps due to the smaller set of reference translations per source prompt (en-vi: 56, en-pt: 131) and high Precision of the “Unweighted” model for en-pt.

### Submitted Systems

We tested our systems on the official blind development set to select the best performing models for final evaluation on the test set. For Portuguese and Vietnamese, our official submissions include frequency-aware hypothesis generation and hypothesis filtering:

- **en-vi** C2: Frequency-aware (10-best) + Frequency-aware (filtered 50-best)
Table 6: Filtering n-best lists consistently improves WMF1 and substantially reduces the size of the output set (K).

| Method                        | en-vi P       | en-vi WR | WMF1 | K     | en-pt P       | en-pt WR | WMF1 | K     |
|-------------------------------|---------------|----------|------|-------|---------------|----------|------|-------|
| No filtering                  | 31.00         | 70.31    | 37.69| 50    | 44.75         | 57.21    | 42.84| 50    |
| Reranker                      | **69.71**     | 46.85    | 50.67| 9     | 67.44         | 41.82    | 45.51| 14    |
| Classifier with CE loss       | 69.70         | 47.74    | 48.77| 12    | 69.26         | 42.70    | 46.60| 10    |

Table 8: Impact of dropping one feature type (§ 3.2) at a time from the “All” configuration for en-vi classifier.

| Translations                  | en-pt | en-vi |
|-------------------------------|-------|-------|
|                               | Ent-4| n     | Ent-4| n     |
| OpenSubs                      | 2.34  | 10    | 2.53  | 10    |
| Unweighted                    | 2.60  | 10    | 2.65  | 10    |
| Frequency-Aware               | 2.59  | 10    | 2.67  | 10    |
| Filtered                      | **2.95** | 13    | **2.71** | 11    |
| Reference                      | 3.93  | 131   | 3.23  | 56    |

Table 9: Diversity in translation sets: Filtered sets are more diverse, bridging 40% of the gap between baseline and reference translations for en-pt.

**en-pt** C4: Frequency-aware (10-best) + Frequency-aware (filtered 50-best) + Unweighted (10-best) + Unweighted (filtered 50-best)

We did not build hypothesis filtering models for the other languages, and submitted systems based only on unfiltered models:

**en-ja** Frequency-aware (50-best) + Unweighted (50-best)

**en-hu** Frequency-aware (10-best) + Unweighted (10-best)

**en-ko** Frequency-aware (50-best) + Unweighted (50-best)

Table 10 and 11 compares our submissions to baselines, as well as top and median submissions across participants, for all the languages. On our focus languages (en-pt and en-vi), where systems benefitted from both frequency-aware generation and filtering models, our submissions obtain a Weighted Macro F1 score of 0.539 for en-vi and 0.525 for en-pt on the official test set, achieving a rank of 2nd and 4th on the leader-board, within 2% of the top performing submission. On the other language pairs, where our submissions did not use
any filtering, Weighted Macro F1 outperform the baselines and median submission consistently. Interestingly on the en-ja task, our system ranks second amongst all the submissions despite not using any filtering.

| Method | en-vi | en-pt | en-ja | en-hu | en-ko |
|--------|-------|-------|-------|-------|-------|
| AWS    | 0.210 | 0.211 | 0.042 | 0.298 | 0.040 |
| Fairseq| 0.267 | 0.151 | 0.031 | 0.130 | 0.054 |
| Median | 0.382 | 0.451 | 0.214 | 0.298 | 0.047 |
| Top    | 0.547 | 0.557 | 0.316 | 0.598 | 0.413 |
| Ours   | 0.537 | 0.538 | 0.283 | 0.492 | 0.254 |

Table 10: Excerpt from official results: weighted Macro F1 on the STAPLE dev set

| Method | en-vi | en-pt | en-ja | en-hu | en-ko |
|--------|-------|-------|-------|-------|-------|
| AWS    | 0.198 | 0.213 | 0.043 | 0.281 | 0.041 |
| Fairseq| 0.254 | 0.136 | 0.033 | 0.124 | 0.049 |
| Median | 0.377 | 0.436 | 0.239 | 0.452 | 0.230 |
| Top    | 0.558 | 0.552 | 0.318 | 0.555 | 0.404 |
| Ours   | 0.539 | 0.525 | 0.294 | 0.469 | 0.255 |

8 Conclusion

We proposed two strategies to obtain multiple outputs that mimic translations by produced by language learners from a standard neural MT model. Our experiments showed that (1) finetuning MT models using all reference translations and their weight yields more diverse n-best hypotheses that better reflect learner preferences, and (2) filtering these n-best lists using a feature-rich classifier trained to maximize an approximation of the STAPLE evaluation metric yields further improvements. Combinations of systems that use these two strategies approach the top scoring submission in the official evaluation.

While these results suggest that some degree of output diversity can be achieved with little change to core neural MT models, oracle scores obtained with unfiltered n-best lists indicate that better modeling the space of learner translations might benefit both candidate generation and the filtering model in future work.
