ABSTRACT

A number of nucleoside mono- and diphosphites and phosphonates containing 1,2-dicarbadodecaborane (12) (1a-6b) at 5'-position of the sugar moiety have been synthesized in good yields. Experimental details along with the spectroscopic and analytical data, supporting the formation of the title compounds, are presented. These constitute a new generation of boron compounds that are envisioned to be useful in cancer treatment via Boron Neutron Capture Therapy (BNCT).

INTRODUCTION

The concept of BNCT was first proposed by Locher some sixty years ago /1/. However, the successful application of BNCT for the treatment of cancer still presents a challenge in medical research. Over the last decade or so, various boron-containing analogues of biologically active compounds such as amino acids /2/, peptides /3/, porphyrins /4/, polyamines /5/, nucleosides, as well as DNA binders /6/, have been synthesized and evaluated for their possible use in BNCT. Such analogues might function in a manner similar to their naturally occurring counterparts and become selectively incorporated into either proliferating or more metabolically active tumor cells. The requirement of 25-30 µg of 10 B atoms per gram of tumor for effective BNCT /7/ has led researchers to incorporate 1, 2-dicarbadodecaborane (o-carborane) as the integral part of many cancer drugs /8/. The C2B10 carborane cage has unique electronic and steric properties that also make it an intriguing moiety in drug design /9/. Boron containing nucleosides are potentially attractive because they should be (1) taken up selectively into tumor due to high mitotic rate of tumor cells vs. normal cells, (2) intra-cellularly converted to the corresponding nucleotides by phosphorylation, and (3) incorporated into tumor DNA, thereby enhancing the cytotoxicity of neutron capture therapy /10/. Early work focused on the development and synthesis of boron-containing purine and pyrimidine bases in which the boron atom was placed within the purine or pyrimidine nucleus and flanked by two nitrogen atoms /11/. Several boron containing nucleosides have also been synthesized with a borane, cyanoborane, dihydroxylboryl, and
carboranyl unit attached to a nucleic acid base /12/. Nonetheless, an ideal BNCT drug should exhibit the hydrolytic stability of the P-C(cage)-nucleotide linkages under physiological conditions without substantial cytotoxicity to the normal cells. Therefore, construction of such linkages is warranted. Consequently, our preliminary results indicated that several prototype carboranyl-substituted adenosine diphosphate (ADP) can be synthesized and their chemistry explored /13/. Thus, this work led us to explore similar species containing carborane cages at 5'-position of the sugar moiety with the hope of serving a dual purpose in providing a significant boron concentration as well as mimicking the naturally occurring nucleosides in the living system /2,3/12/. Here we report the syntheses and characterization of novel carboranyl derivatives of nucleoside mono- and diphosphites and phosphonates.

**EXPERIMENTAL**

**Materials**

All solvents, chemicals and reagents were of analytical grade and used without further purification unless otherwise noted. Baker analyzed silica gel (60-200 mesh) was used for flash column chromatography. 1,2-Bis(chlorophenylphosphino)-1,2-dicarbadodecaborane (1), 1-phenyl-2-(chlorophenylphosphino)-1,2-dicarbadodecaborane (2), 1-methyl-2-(chlorophenylphosphino)-1,2-dicarbadodecaborane (3) were prepared by the methods described elsewhere /14/. 1,2-Bis(chloromethylphosphino)-1,2-dicarbadodecaborane (4), 1-phenyl-2-(chloromethylphosphino)-1,2-dicarbadodecaborane (5), 1-methyl-2-(chloromethylphosphino)-1,2-dicarbadodecaborane (6) were synthesized by the methods described in the literature /15/. *Closo-*1,2-C2B10H12 (o-carborane), *closo-*1-Ph-1,2-C2B10H11 (phenyl-o-carborane), and *closo-*1-Me-1,2-C2B10H11 (methyl-o-carborane) were obtained from KATCHEM and used as received. N6'-3'-O-dibenzoylethyl-2'-deoxyadenosine, N2'-isobutyryl-3'-acetyl-2'-deoxyguanosine, phenyl dichlorophosphine and methyl dichlorophosphate were obtained from Sigma-Aldrich and used without further purification. Tetrahydrofuran (THF), triethylamine (TEA) were dried over sodium metal and benzophenone and doubly distilled before use.

**Spectroscopic and analytical procedures**

The 1H, 11B, 31P and 13C NMR spectra were recorded on a Bruker Fourier-transform multinuclear NMR spectrometer at 200, 64.2, 80.2 and 50.3 MHz, respectively. Infrared spectra were recorded using a Nicolet Magna 550 FT-IR spectrophotometer with OMNIC software. Elemental analyses were obtained in house using a Perkin Elmer 2400 CHN elemental analyzer.

**Synthetic procedures**

All experiments were carried out in 100 mL Pyrex glass round-bottom flasks of each fitted with a nitrogen inlet and containing a magnetic stirring bar. All known compounds among the products were identified by comparing their IR and NMR spectra and melting points with those of authentic samples.
A 0.28 mmol (0.12 g) sample of 1,2-bis(chlorophenylphosphino)-1,2-dicarbadodecaborane (1), N\textsuperscript{6}-3'-O-dibenzoyl-2'-deoxyadenosine (0.56 mmol, 0.26 g), and triethylamine (0.58 mmol, 0.057 g) was dissolved in anhydrous THF in an inert atmosphere and the mixture was stirred for 10 h. After removing the insoluble materials by filtration, the solvent in the filtrate was removed under reduced pressure and the resulting residue was dissolved in chloroform (30 mL) and washed with water (3 x 20 mL) in an extraction procedure. The organic layer in the extract was dried over MgSO\textsubscript{4} filtered and concentrated under reduced pressure to produce a solid residue that was purified by column chromatography, using silica gel and a solvent mixture of ethyl acetate: hexane (7:3) as an eluent, to isolate 1a as a yellow solid in 52 % yield (0.146 mmol, 0.19 g).

In an inert atmosphere, a 0.28 mmol (0.12 g) sample of 1,2-bis(chlorophenylphosphino)-1,2-dicarbadodecaborane (1), N\textsuperscript{2}-isobutyryl-3'-acetyl-2'-deoxyguanosine (0.57 mmol, 0.21 g), and triethylamine (0.59 mmol, 0.057 g) were dissolved in anhydrous THF and the mixture was stirred for 18 h. After removing the insoluble materials by filtration, the solvent in the filtrate was removed under reduced pressure and the resulting residue was extracted with chloroform (25 mL) and washed with water (3 x 15 mL). The organic layer in the extract was dried over MgSO\textsubscript{4}, filtered and concentrated under reduced pressure to produce a solid residue that was purified by column chromatography, using silica gel and a solvent mixture of ethyl acetate: hexane (7:3) as an eluent, to isolate 1b as a yellow solid in 58 % yield (0.162 mmol, 0.17 g).
1-Phenyl-2-[phenylphosphino-N^{6},3'-O-dibenzoyl-2'-deoxyadenosine]-1,2-dicarbadodecaborane (2a)

In a procedure identical to that described above for 1a and 1b, the reaction involving 0.28 mmol (0.10 g) of 1-phenyl-2-(chlorophenylphosphino)-1,2-dicarbadodecaborane (2), N^{6},3'-O-dibenzoyl-2'-deoxyadenosine (0.30 mmol, 0.13 g), and triethylamine (0.32 mmol, 0.028 g) in anhydrous THF produced 2a as a white solid in 62 % yield (0.171 mmol, 0.13 g). M. P. >173 °C dec. Spectroscopic and Analytical Data: \(^1^H\) NMR (DMSO, relative to Me$_4$Si) \(\delta\) 8.08 [s, 1H, H-8], 7.99 [s, 1H, H-2], 7.48-8.50 [m, 20H, aromatic H], 6.28 [m, 1H, H-1'], 4.68 [m, 1H, H-3'], 4.18 [m, 1H, H-4'], 3.96 [m, 2H, H-5'], 2.31 [m, 2H, H-2'], 1.10-1.30 [br, 10H, BH]; \(^{11}\)B NMR (DMSO, relative to BF$_3$OEt$_2$) \(\delta\) -14.36 [4B, \(J_{BH} = \) unresolved], -11.89 [2B, \(J_{BH} = 156.8\) Hz], -9.56 [2B, \(J_{BH} = 151.4\) Hz], -7.42 [1B, \(J_{BH} = 135.8\) Hz], -5.21 [1B, \(J_{BH} = 143.4\) Hz]; \(^{31}\)P NMR (DMSO, relative to H$_3$PO$_4$) \(\delta\) 8.10 [s]; \(^{13}\)C NMR (DMSO, relative to Me$_4$Si) \(\delta\) 177.80 [C=O], 130.49-141.00 [aromatic], 82.00 [carborane C]; IR (KBr pellet, cm$^{-1}$) 2489 [v(B-H)], 710, 1611, 1471 [v(aromatic)]. 1-Methyl-2-[methylphosphinate- N$^2$-isobutyryl-3'-acetyl-2'-deoxyguanosine]-1,2-dicarbadodecaborane (6b)

In a procedure identical to that described above, the reaction of 0.29 mmol (0.08 g) sample of 1-methyl-2-(chloromethylphosphate)-1,2-dicarbadodecaborane (6), N$^2$-isobutyryl-3'-acetyl-2'-deoxyguanosine (0.31 mmol, 0.11 g), and triethylamine (0.35 mmol, 0.030 g) in anhydrous THF produced a solid residue that was extracted with 1:2 mixture of ethyl acetate:chloroform (20 mL) and washed with water (3 x 20 mL). The separation and the purification steps, as described above for 1a and 1b, produced 6b as a yellow solid in 54% yield (0.157 mmol, 0.09 g). M. P. >220 °C, dec. Spectroscopic and Analytical Data: 

'H NMR (DMSO, relative to Me$_4$Si) δ 8.28 [s, 1H, H-8], 5.86 [m, 1H, H-1'], 4.75 [m, 1H, H-3'], 4.08 [m, 1H, H-4'], 3.95 [s,
RESULTS AND DISCUSSION

We recently reported the synthesis of carboranyl bis(adenosine diphosphate) (CBADP) in which diphosphorylated adenosine base was attached to both the carbons of the carborane cage. The specific synthetic route involved the reaction of 1,2-bis(methyldichlorophosphate)-1,2-dicarbadodecaborane with 5'-methoxy monophosphorylated-3'-O-and N6-protected deoxyadenosine/13/. However, the present work involves the syntheses of a number of carboranyl nucleosides in which the phosphino or phosphate substituted bases are attached either to one carbon or both the carbons of the carborane cage, instead of the diphosphorylated bases. In addition, the present work has been performed with two bases (adenosine and guanosine). The synthetic route has been simplified by one step reaction involving the chlorophenylphosphino-substituted and chloromethylphosphate-substituted carboranes with adenosine or guanosine. All of the carboranyl derivatives of mono- and diphosphites and phosphonates have been characterized by their elemental analyses, NMR spectra and IR spectra. The $^{31}$P NMR resonance was observed between 7.00-8.25 ppm as a broad singlet, presumably due to a long-range coupling of the phosphorus with the boron atoms of the cage. It is of interest to note that the $^{31}$P chemical shifts for a number of $\textit{closo-o}$-carboranylphosphines appear in the range of 5.4 ppm to 54.2 ppm depending on the substituents on the phosphorus atom/16/. On the other hand, the $^{11}$B NMR chemical shifts of $\textit{closo-o}$-carboranylphosphines appear in the range of $-1$ ppm to $-13$ ppm/16/, and are almost similar to those of 1a – 3b whose $^{11}$B NMR chemical shifts appeared in the range of $-2.00$ to $-16.00$ ppm indicating the presence of similar cage functionality on the cage carbons in these compounds. The IR spectra of 1a – 3b exhibited the characteristic B-H stretching absorptions in the region of 2560-2583 cm$^{-1}$ that indicates the presence of carborane cages in these species. The $^{13}$C NMR spectra, in addition to the resonances due to alkyl and/or aromatic functionalities in the expected region of chemical shifts, showed peaks in the region of $\delta$ 70.0 - 86.0 ppm due to cage carbons of the $\textit{closo-o}$-carborane unit and are quite close to the values of $\delta$ = 65.1 – 84.5 ppm observed for
Scheme 1: Synthesis of 1,2-bis[phenylphosphinoxy]nucleoside]-1,2-dicarbadodecaborane and 1-phenyl or methyl-2-[phenylphosphinoxy]nucleoside]-1,2-dicarbadodecaborane.

1. \( R = \text{P(Ph)Cl} \)
2. \( R = \text{Ph} \)
3. \( R = \text{Me} \)

1a. \( R' = \text{R''; R''' = Bz; Y = Ade} \)
1b. \( R' = \text{R''; R''' = Ac; Y = Gua} \)
2a. \( R' = \text{Ph; R'' = Bz; Y = Ade} \)
2b. \( R' = \text{Ph; R'' = Ac; Y = Gua} \)
3a. \( R' = \text{Me; R'' = Bz; Y = Ade} \)
3b. \( R' = \text{Me; R'' = Ac; Y = Gua} \)

\[ \text{Ade} = \]

\[ \text{Gua} = \; \text{iBu-NH} \]
The proton NMR spectra were consistent with all of the moieties present in 1a – 3b.

The compounds 1,2-bis[methylphosphatedeoxynucleoside]-1,2-dicarbadodeca-borane, 4a-b, and 1-phenyl or methyl-2-[methylphosphatedeoxynucleoside]-1,2-dicarbadodecaborane, 5a-b or 6a-b, were obtained in 50-58% yield from the reaction of the appropriate deoxynucleoside and the disubstituted (chloromethylphosphate), or the mono-substituted (chloromethylphosphate) carborane. The deprotection of the protecting groups on the bases in the final compounds was not tried. All of the products shown in Scheme 2 have been characterized by elemental analyses, $^1$H, $^{11}$B, $^{13}$C and $^{31}$P NMR spectra and IR spectra (see Experimental section). The chemical shift values of $\delta = 8.25$ ppm in the $^{31}$P NMR spectra, $\delta = -2.61$ to $-16.38$ ppm in the $^{11}$B NMR spectra, and $\delta = 71.0 - 83.6$ ppm in the $^{13}$C NMR spectra, in addition to those in the $^1$H NMR spectra, are all in the range observed for the recently reported carboranyl bis(adenosine diphosphate) /13/ indicating the presence of similar linkages that exist between the exo-polyhedral moieties and the close-o-carboranyl cage in 4a-b, 5a-b and 6a-b. The IR spectra showed the characteristic B-H stretching frequencies in the region of 2565-2580 cm$^{-1}$. Nonetheless, the utility of these compounds as a tumor-targeting species for effective boron neutron capture therapy (BNCT) or in photodynamic therapy (PDT) will be investigated in the near future. Since all of the reaction sequences, described in Schemes 1-2, are of a general nature, they represent a blueprint for the synthesis of a family of potentially valuable hydrolytically stable carborane nucleic acid constructs. Studies evaluating the in-vitro and in-vivo localizing ability of these novel compounds are currently being carried out in our laboratories.

ACKNOWLEDGEMENT

This work was supported by grants from the National Science Foundation (CHE-9988045, CHE-0241319), the donors of the Petroleum Research Fund, administered by the American Chemical Society, and Northern Illinois University through a Presidential Research Professorship. The Forschungspreis der Alexander von Humboldt-Stiftung is also hereby gratefully acknowledged.
