Efficacy and safety of sertraline for the treatment of premature ejaculation
Systematic review and meta-analysis

Abstract
Background: Evidence on the efficacy and safety of sertraline in patients with premature ejaculation (PE) was inconsistent. The objective of this article is to evaluate the efficacy and safety of sertraline for the treatment of PE.

Methods: We searched Medline (OVID), Embase, the Cochrane Library, and 2 Chinese databases for randomized controlled trials (RCTs) and randomized crossover trials (RTs) that evaluated the efficacy and safety of sertraline in patients with PE. A meta-analysis was performed to calculate their pooled estimates with 95% confidence interval.

Results: Of the 645 records obtained, we included 12 RCTs and 2 RTs (n=977). Meta-analysis showed that sertraline prolonged intravaginal ejaculation latency time (IELT) in PE patients (standard mean difference (SMD)=2.14, 95% CI 1.20 to 3.08). Subgroup analyses indicated a prolonged IELT for different treatment courses: 4 weeks (SMD=2.66, 1.06 to 4.26), 6 weeks (SMD=0.95, 0.31 to 1.58), and 8 weeks (SMD=1.81, 0.78 to 2.85). The sexual satisfaction rates of patients (SMD=2.20, 1.57 to 2.84) and spouses (SMD=2.27, 1.44 to 3.09) were also improved. We observed a significant increased risk of gastrointestinal upset (risk ratio=2.71, 1.39 to 5.26) in the sertraline group.

Conclusion: Sertraline can prolong IELT of PE patients, improve sexual satisfaction rates of patients and spouses, but increase risk of gastrointestinal upset.

Abbreviations: AEs = adverse events, APE = acquired premature ejaculation, CIs = confidence intervals, IELT = intravaginal ejaculation latency time, IIEF = international index of erectile function, LPE = lifelong premature ejaculation, PE = premature ejaculation, PDE 5 = type 5 phosphodiesterase, RCTs = randomized controlled trials, RTs = randomized crossover trials, SMD = standard mean difference, SSRIs = selective serotonin reuptake inhibitors, TCAs = tricyclic antidepressants.

Keywords: premature ejaculation, intravaginal ejaculation latency time, sertraline, sexual satisfaction rate, systematic review

1. Introduction
Premature ejaculation (PE) is a common sexual dysfunction which was defined by the International Society for Sexual Medicine as the following:
1. Ejaculation that always or nearly occurs prior to or within about 1 minute of vaginal penetration from the first sexual experience (lifelong premature ejaculation, LPE), or a clinically significant reduction in latency time, often to about 3 minutes or less (acquired premature ejaculation, APE); 2. the inability to delay ejaculation on all or nearly all vaginal penetrations; 3. negative personal consequences, such as distress, bother, frustration, and/or the avoidance of sexual intimacy.[1]

PE has been recognized for more than 100 years,[2] and the prevalence of LPE is about 4% of the general population based on previous published literatures and guidelines.[3] Pharmacotherapy of PE includes traditional local anesthetics (such as lidocaine and prilocaine), selective serotonin reuptake inhibitors (SSRIs) and tricyclic antidepressants (TCAs) (such as dapoxetine, paroxetine and clomipramine, type 5 phosphodiesterase (PDE 5) inhibitors, tramadol and oxytocin, etc. Among the above treatments, only dapoxetine was approved in some countries, while others were off-label use.[4]

SSRIs are increasingly used for PE[4] and relevant clinical trials have been published.[5] Waldinger et al hypothesized that lifelong premature ejaculation is a neurobiological phenomenon associated with reduced transmission of central serotonin (5-HT\textsubscript{2C} and/or 5-HT\textsubscript{2A}).[6] Olivier et al have revealed that 5-HT showed a comprehensive inhibition of ejaculation, and the reduction of central 5-HT content was one of the risk factors for PE.[7] Sertraline is a highly selective SSRI that blocks the uptake of 5-HT by platelets, resulting in the increase of plasma 5-HT concentrations and the improvement of PE.[8]
However, there was no systematic review on the efficacy and safety of sertraline in patients with PE. Furthermore, due to inconsistent evidence and its off-label use in many countries, the objective of this article is to review the evidence of the efficacy and safety of sertraline for PE.

2. Methods

2.1. Search strategy
We searched Medline (OVID), Embase, the Cochrane Library, and 2 Chinese databases including Chinese Biomedicine Literature Database and Chinese Sci-tech Journals Database from inception to September 2018. The following keywords were used in search terms: “premature ejaculation”, “rapid ejaculation”, “rapid climax”, “premature climax” and “early ejaculation” for the disease, and terms “sertraline” for the medication. We used the Boolean logic “AND” to combine the two sets of terms. We limited the language of articles to English and Chinese only. We also manually searched the reference list of the included studies, journals and ClinicalTrials.gov as a supplementary source for the literature search. The systematic review with meta-analysis was registered on PROSPERO (No. CRD42018109413). This systematic review and meta-analysis is exempt from ethical approval as the analysis involves only already published and anonymized data.

2.2. Study selection and outcome measures
Independent investigators (ZMY, SDC, and QYT) manually screened the records for potentially eligible studies by screening the title and abstract in the first stage, and full-text screening in the second. In title and abstract screening stage, studies appearing to meet the inclusion criteria, or with insufficient information to make a clear judgment, judged by either authors or both, were included in the full-text screening process. We obtained full texts of all these studies for the full-text screening. We resolved disagreements through discussion, and if necessary, a third investigator (SDZ) was consulted. We included studies if they met the following criteria:

![Flow diagram for study selection](image-url)
| Studies         | Country | Type of study | Participants                                                                 | Intervention | Duration | Outcomes                  |
|----------------|---------|---------------|-------------------------------------------------------------------------------|--------------|----------|---------------------------|
| Arafa 2006[11] | Egypt   | RT            | PE patients married or in a stable relationship Age: 19 ~ 70 years Sertraline: 77; Placebo: 70 Baseline: NR | 50 mg/day    | 4 weeks  | AIEP IELT Side effects    |
| Waldinger 2001[12] | Netherlands | RCT          | Heterosexual patients with lifelong PE married or in a stable relationship Age: 18 ~ 65 years Sertraline: 8; Placebo: 10 Baseline: no significant difference | 50 mg/day    | 6 weeks  | IELT Side effects         |

(continued)
1. Randomized controlled trials (RCTs) or randomized crossover trial (RTs),
2. enrolling PE patients above 18 years old; PE was defined as involuntary ejaculation before or after vaginal penetration within 1 to 2 minutes on at least 50% of occasions of attempted intercourse, or in accordance with diagnosis in the fourth edition of the American Diagnostic and Statistical Manual of Mental Disorders.\(^9\)
3. comparing sertraline with a blank control or a placebo control. Patients combined with the following diseases were excluded: erectile dysfunction, mental illness, alcohol or drug abuse, urethritis or prostatitis.

The primary efficacy outcomes focused on intravaginal ejaculation latency time (IELT). The secondary efficacy outcomes included patient sexual satisfaction, spouse sexual satisfaction and international index of erectile function (IIEF). The safety outcome was the incidence of adverse events (AEs).

### 2.3. Data extraction and quality assessment

Data extraction was performed by independent investigators (ZMY, SDC, and QYT) according to a predesigned data-collection form. Extracted information included authors, publication year, participant characteristic (participation eligibility criteria, gender, and age), intervention information (the dosage and duration) and outcome of interest.

Investigators independently assessed the methodological quality of included studies. We assessed the risk of bias in the eligible RCTs and RTs with the Cochrane risk of bias assessment tool.\(^10\) In the case of missing data, we contacted the authors of eligible studies for clarifications. All disagreements about data extraction and quality assessment were resolved through discussion among all authors.

### 2.4. Statistical analysis

We compared the treatment effect through meta-analysis in an intention to treat manner (following the allocation of participants in studies). Only the results of studies evaluating similar interventions in similar participants were pooled. Due to the different data units between studies, we calculated the standard mean difference (SMD) and their 95% confidence intervals (CIs) for continuous outcomes and risk ratio (RR) for categorical outcomes. We performed meta-analyses with RevMan 5.3 software using a random-effect model. Statistical heterogeneity

**Table 1** (continued).

| Studies   | Country | Type of study | Participants                                                                                                                                  | Intervention | Duration | Outcomes |
|-----------|---------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|--------------|----------|----------|
| Zhu 2015\(^23\) | China   | RCT           | Heterosexual patients with PE in a stable relationship<br>Age: 27.1 ± 4.7 years, 27.8 ± 4.1 years<br>Sertraline combined with four-spot caressing: 30; Four-spot caressing: 30<br>Baseline: no significant difference | 50 mg/day    | 12 weeks | IELT<br>CIPE-5 (Q4–7,10)<br>Adverse effects |
| Li 2018\(^24\) | China   | RCT           | Heterosexual patients with PE in a stable relationship<br>Age: 20 ~45 years<br>Sertraline combined with psychological counseling: 38; Psychological counseling: 38<br>Baseline: no significant difference | 50 mg/day    | 8 weeks  | IELT<br>CIPE-5<br>Patient’s and spouse’s Satisfaction<br>Adverse effects |

APE = the Arabic index of premature ejaculation; IELT = intravaginal ejaculation latency time; IEF = International Index of Erectile Function; CIPE-5 = Chinese index of sexual function for premature ejaculation; NOx = Nitric oxide; NR = not reported; PE = premature ejaculation; RT = randomized crossover trial; RCT = randomized control trial.
was assessed with chi-square test and quantified with the $I^2$ test. Subgroup analyses by duration of treatment and definitions of PE were conducted; sensitivity analysis was conducted by excluding studies that used different effect measures from other studies to test the robustness of the results. Finally, the publication bias was examined by funnel plot if the number of included studies ≥10. $P < .05$ was considered statistically significant.

### 3. Results

#### 3.1. Study selection

The initial search identified 645 relevant records and 459 records were left after removing duplicates. Of these, 421 of 459 were excluded after title/abstract screening, and 38 reports were eligible for full-text review. After full-text review, we excluded 24 reports with following reasons: 7 studies were not RCTs or RTs; 4 studies had not reported the end-points; 7 studies were not patients with PE; 1 study was duplicated; 4 studies were not sertraline alone compared with placebo and one study was not English. Finally, we included 14 articles with 977 patients, including 12 RCTs and 2 RTs.

The process of literature search and study selection is presented in Figure 1.

#### 3.2. Study characteristics and quality assessment

In 12 studies, the dose of sertraline was 50mg/d, and in 1 study, the dose of sertraline was 50 to 200mg/d. The duration of treatment included 4 weeks, 6 weeks, 8 weeks, and 12 weeks (Table 1).

The risk of bias of 11 included literatures was unclear, and 3 were high. We classified 5 RCTs at low risk of bias in the domain of random number generation.

Five RCTs used the

| Studies | Random sequence generation | Allocation concealment | Blinding (participants) | Blinding (outcome assessor) | Incomplete outcome data | Selecting reporting | Other source of bias | Total |

double-blind design and adopted intention-to-treat principle to analyze data. An overall assessment in domains of risk of bias were summarized in Fig. 2. Incomplete outcome data and selective reporting were the dominant causes of high risk of bias (Table 2).

3.3. Efficacy

3.3.1. IELT. Fourteen articles (977 patients) reported the IELT data. But one study, which did not distinguish data from primary premature ejaculation and secondary premature ejaculation, was excluded. Finally, thirteen articles (830 patients) were included. One study reported both the IELT change values recorded by the patient and the spouse. Since there were missing data recorded by the spouse, only the IELT recorded by the patients was used. Meta-analysis showed that sertraline can prolong the IELT (changes of IELT, SMD 2.14, 95% CI 1.20 to 3.08, \( P < .00001; I^2 = 96\%\)) (Fig. 3A).

Subgroup analysis was performed according to the duration of treatment. Results indicated that 4 weeks (516 patients, SMD 2.66, 95% CI 1.06 to 4.26, \( P = .001; I^2 = 98\%\)), 6 weeks (44 patients, SMD 0.95, 95% CI 0.31 to 1.58, \( P = .004; I^2 = 0\%\)), 8 weeks (330 patients, SMD 1.81, 95% CI 0.78 to 2.85, \( P = .0006; I^2 = 94\%\)) and 12 weeks (30 patients, SMD 1.06, 95% CI 0.51 to 1.60) of sertraline treatment can all prolong IELT of PE patients (Fig. 3B).

Of the included studies, PE was defined as uncontrollable ejaculation before/after entering the vagina within 1 min in 7 studies, and within 2 minutes in 3 studies, the remaining three studies had no clear time definition for PE. Subgroup analysis was performed by ejaculation time defined for PE. Meta-analysis showed that the changes of IELT in the 1-min sertraline group (302 patients, SMD 1.49, 95% CI 0.58 to 2.40, \( P = .001; I^2 = 91\%\)) and 2-minute group (222 patients, SMD
1.78, 95%CI 0.17 to 3.39, P = .03; I² = 96%) was both higher than that of the control group (Fig. 3C).

3.3.2. Patients’ sex satisfaction rate. Six studies reported patients’ sexual satisfaction rates after treatment.[16–18,20,22,24] Patients’ sexual satisfaction rates were evaluated by 6, 7, and 8 items in the IIEF (0–15 points) among 3 studies,[20,22,24] and meta-analysis showed that sertraline improved patients’ sexual satisfaction rates (SMD 2.20, 95%CI 1.57 to 2.84, P < .00001). Among the other 3 studies that cannot be pooled, 1 study[17] showed that sertraline improved patients’ sexual satisfaction rates (SMD 0.68, 95%CI 0.10 to 1.26, P = .02) by 0 to 4 items evaluation; the other 2 studies[16,18] reported percentage of patients’ sexual satisfaction and found the sexual satisfaction rates was 51.4% and 41.7% in the sertraline group after treatment, 20% and 19.4% in the control group, respectively.

3.3.3. Spouses’ sexual satisfaction rate. Seven studies reported spouses’ sexual satisfaction rates after treatment.[16–18,20–22,24] Spouses’ sexual satisfaction rates were evaluated by 6, 6, and 8 items in the IIEF (0–15 points) among 3 studies,[20,22,24] and meta-analysis showed that sertraline improved spouses’ sexual satisfaction rates (SMD 2.27, 95%CI 1.44 to 3.09, P < .00001). Among the other 4 studies that cannot be pooled, 1 study[17] showed that sertraline improved the spouses’ sexual satisfaction, but the difference was not statistically significant (SMD 0.45, 95%CI −0.18 to 1.09, P = .16) by 0 to 4 items evaluation; the other 3 studies[16,18,21] reported percentage of spouses’ sexual satisfaction rates and 2 studies[16,18] found the sexual satisfaction rates were 57.1% and 30.6% in the sertraline group after treatment, 14% and 11.1% in the control group, respectively; another study[21] found the sexual satisfaction rates of the sertraline group changed from 14.7% before treatment to 88.2% after treatment, and 17.5% to 25% in the control group, respectively.

3.4. Safety
Ten studies reported AEs in the sertraline group and the control group during the follow-up periods. Among them, a significant increased risk of gastrointestinal upset was observed in pooled results of 8 studies[13,15–17,20,21,23,24] (RR 2.71, 95%CI 1.39 to 5.28, P = .004). While there was no statistically difference in pooled results of headache, dizziness, drowsiness, dry mouth and fatigue (Fig. 4). Another 2 studies[18,23] reported 4 cases and 1 case of headache and dizziness in the sertraline group, respectively. Two studies[12,14] reported slight decreased in sexual desire and penile rigidity in the sertraline groups.

3.5. Sensitivity analysis and publication bias
In 1 study,[12] data of standard mean difference were converted between arithmetic means and geometric means. Therefore, the sensitivity analysis was performed by excluding this study. No significant changes in the results of IELT (SMD 2.26, 95% CI 1.26 to 3.26, P < .00001; I² = 97%) were indicated. For Mendels et al.[17] both the IELT change values recorded by the patient and the spouse were reported, only the IELT recorded by the patients was used. No significant changes in the results of IELT (SMD
2.25, 95% CI 1.23 to 3.27, \(P < .00001; I^2 = 97\%\) were indicated when excluding this study.

The funnel plot was used to assess publication bias, there has been little evidence of publication bias for the included studies that assessed changes of IELT (Fig. 5).

4. Discussion
In this study, the efficacy and safety of sertraline for the treatment of PE was evaluated by a systematic review of RCTs and RTs. The results showed statistically significant difference in changes of IELT between sertraline groups and control groups, and
sertraline prolonged the IELT of PE patients. In subgroup analyses, all different durations of sertraline treatment and all definitions of PE showed prolonged IELT. Studies reported sexual satisfaction rates of patients and spouses both suggested improvements by sertraline treatments. The most common AE in sertraline groups was gastrointestinal upset, which was significantly different from control groups. Headache, dizziness, drowsiness, and dry mouth were common, but no significant differences were found compared with control groups.

Guidelines by the European Association of Urology suggested that the etiology and pathophysiology of PE is largely unknown, with few data to support suggested biological and psychological hypotheses. Recent researches suggested that some neurobiological and genetic variation factors might cause LPE, and psychological/environmental factors might maintain or enhance this condition. A systematic review including 18,035 patients suggested that depression increased risk of PE (OR 1.63, 95% CI 1.42 to 1.87). LPE can be explained by low 5-HT concentration, low 5-HT2C receptor sensitivity and/or 5-HT1A receptor hypersensitivity. A meta-analysis of SSRIs for PE showed that paroxetine appeared to exert the strongest ejaculation delay (1492% IELT increase, 95% CI 918 to 2425%), followed by sertraline (790%, 95% CI 532 to 1173%), clomipramine (512%, 95% CI 234 to 1122%) and fluoxetine (295%, 95% CI 172 to 306%).

Compared with previous studies, our study focused on sertraline. In addition to the efficacy and safety of sertraline in the treatment of PE, we also conducted subgroup analyses to further explore the treatment courses of sertraline and results by different definition of PE. Meanwhile, data of standard mean difference were converted between arithmetic means and geometric means. Due to the common AEs of gastrointestinal upset, headache, dizziness, and drowsiness, sertraline may bring impacts on the daily work of PE patients whom are generally under 70 years old.

Our study has some limitations. First, most of the studies included in this systematic review had a moderate risk of bias, some of the studies were heterogeneous between the subgroups and there was a certain publication bias. Second, part of the studies were not simple comparisons between sertraline and placebo but based on the combination of another active drug or intervention (behavioral therapy, doxazosin, Yimusake, terazosin, tadalafil, 4-spot caressing and psychological counseling). Third, the IELT measurements in the studies were mostly timed by stopwatch, which had the disadvantage of being intrusive and potentially disruptive of sexual pleasure. Therefore, guidelines recommend that self-estimation by the patient and partner of ejaculatory latency be accepted as the method for determining IELT in clinical practice. In addition, the sample size of the included studies was small, which can affect rigor of the results. Future larger RCTs were needed to explore the drug therapy regimen, in order to obtain the maximum therapeutic effect with the least costs.

A systematic review of 103 studies also demonstrated that serotonin-noradrenaline reuptake inhibitors, tricyclic antidepressants, topical anesthetics, phosphodiesterase-5 inhibitors and opioid analgesics also increased IELT compared with placebo (P < .05). Another review also presented evidence of behavioral techniques, alpha-blockers, experimental treatments such as dorsal nerve modulation, acupuncture and Yoga. Further studies for the assessment of long-term (over 12 weeks) effectiveness and safety of different interventions alone as well as combination therapies are encouraged. Additionally, different treatment effects for PE with primary or acquired causes may be explored. Furthermore, time needed to the increment in the latency time following the vaginal penetration should be considered as outcomes for further studies due to its importance for patients’ and physicians’ decision-making for the off-label use of sertraline.

In conclusion, sertraline can prolong IELT of PE patients, improve sexual satisfaction rates of patients and spouses, but increase risk of gastrointestinal upset.

Acknowledgments
We extend special thanks to Ying-Ying Yan from Peking University Third Hospital and Yuan Zhang from McMaster University for their contribution to this research.
**Author contributions**

ZMY conceived this review. ZMY, SDC and QYT identified reports of trials and extracted data. HLT provided statistical advice. ZMY, SDC and QYT did all statistical analyses, checked for statistical inconsistency and interpreted data. SDC contributed to data extraction and interpretation. ZMY and SDC drafted the report and all other authors (QYT, HLT and SDZ) critically reviewed the article. All authors read and approved the final manuscript.
