2 November 2022

Abstract

We give a nearly linear-time algorithm to approximately sample satisfying assignments in the random $k$-SAT model when the density of the formula scales exponentially with $k$. The best previously known sampling algorithm for the random $k$-SAT model applies when the density $\alpha = m/n$ of the formula is less than $2^{k/300}$ and runs in time $n^{\exp(O(k))}$ (Galanis, Goldberg, Guo and Yang, SIAM J. Comput., 2021). Here $n$ is the number of variables and $m$ is the number of clauses. Our algorithm achieves a significantly faster running time of $n^{1+o(1)}$ and samples satisfying assignments up to density $\alpha \leq 20^{0.039k}$.

The main challenge in our setting is the presence of many variables with unbounded degree, which causes significant correlations within the formula and impedes the application of relevant Markov chain methods from the bounded-degree setting (Feng, Guo, Yin and Zhang, J. ACM, 2021; Jain, Pham and Vuong, 2021). Our main technical contribution is a $o_k(\log n)$ bound of the sum of influences in the $k$-SAT model which turns out to be robust against the presence of high-degree variables. This allows us to apply the spectral independence framework and obtain fast mixing results of a uniform-block Glauber dynamics on a carefully selected subset of the variables. The final key ingredient in our method is to take advantage of the sparsity of logarithmic-sized connected sets and the expansion properties of the random formula, and establish relevant properties of the set of satisfying assignments that enable the fast simulation of this Glauber dynamics.

1 Introduction

The random $k$-SAT model is a foundational model in the study of randomised algorithms. For integers $k, n, m \geq 2$, the random formula $\Phi = \Phi(k, n, m)$ is a $k$-CNF formula chosen uniformly at random from the set of formulas with $n$ Boolean variables and $m$ clauses, where each clause has $k$ literals (repetitions allowed). Here, we consider the sparse regime where the density of the formula, $\alpha = m/n$, is bounded by an absolute constant. An important question is determining the probability that the random formula is satisfiable as a function of its density (in the limit $n \rightarrow \infty$). Interestingly, for all sufficiently large $k$, the probability that $\Phi$ is satisfiable drops abruptly from 1 to 0 when the density $\alpha$ crosses a certain threshold $\alpha_*(k)$. Recently there has been tremendous progress in establishing this phase transition, concluding that $\alpha_*(k) = 2^k \log 2 - \frac{1}{2} (1 + \log 2) + o_k(1)$ as $k \rightarrow \infty$ [16, 13]. Despite the good progress on pinning down this phase transition, finding satisfying assignments for densities up to $\alpha^*$ poses severe challenges. In fact, the best known algorithm [10] for finding a satisfying assignment of a random formula $\Phi$ succeeds up to densities $(1 + o_k(1)) \frac{2^k}{k} \log k$, and going beyond such densities is a major open problem with links to phase transitions [1].

Lately there has been significant interest in the related computational problem of sampling satisfying assignments of $\Phi$ uniformly at random. This problem is closely connected to the problem of estimating the number of satisfying assignments of $\Phi$, also known as the value of the partition function of the model. From a probabilistic viewpoint, the analysis of the partition function depends on subtle properties of the solution set $\Omega$ consisting of the satisfying assignments of $\Phi$ [2, 12, 37, 33]. In this direction, there has been substantial work on finding the so-called free energy of the model, i.e., the asymptotic value of the quantity $\frac{1}{n} \mathbb{E} [\log (1 + |\Omega|)]$. Computing the $k$-SAT free energy is a difficult problem which is still open (roughly, the difficulty comes from the asymmetry of the model and the unbounded degrees), but there have been results for closely related models including the permissive version of the model [12, 33, 14], the regular $k$-SAT model [15], and the regular NAE-SAT model [36, 37]. Very recently, a formula for the free energy of the 2-SAT model was given in [2].

Regarding the algorithmic problem of sampling satisfying assignments uniformly at random, in the random $k$-SAT model progress has been slower relative to other well-studied models on random graphs (such as $k$-colourings or independent sets). One of the main reasons for this is that the usual distribution properties that are typically used to obtain fast algorithms (such as correlation decay and spatial mixing) fail to hold for densities as low as $\alpha = o_k(1)$ [33]. These issues are in fact present already in the bounded-degree $k$-SAT setting, where the formulas are worst-case but every variable is constrained to have a bounded-number of occurrences. For random formulas, these issues are further aggravated by the fact that the degrees of a linear number of variables are unbounded. Very recently, [21] gave an approximate counting algorithm (FPTAS) for the number of satisfying assignments of $\Phi$ when $k$ is large enough and $\alpha \lesssim 2^{k/300}$ (where $\lesssim$ hides a polynomial factor in $1/k$). This algorithm elevates Moitra’s counting method for bounded-degree $k$-SAT [32] to the random formula setting, and is the first polynomial-time approximate-counting algorithm to achieve an exponential-in-$k$ bound on $\alpha$. However, its running time is $n^{\exp(\Theta(k))}$ because the algorithm repeatedly has to enumerate local structures (including solving LPs as a subroutine), which does not scale well with $k$. Hence, the problem of finding a fast algorithm for sampling the satisfying assignments in the random $k$-SAT model has remained open.

In this work we give a fast algorithm that in time $n^{1+o_k(1)}$ approximately samples satisfying assignments of a random $k$-SAT formula of density $\alpha \lesssim 2^{0.039k}$, within arbitrarily small polynomial error. Moreover, our result significantly extends the densities under consideration compared to the previous bound $\alpha \lesssim 2^{k/300}$ from [21]. Our algorithm first runs a Markov chain to sample assignments of a judiciously-chosen subset of variables of $\Phi$ (from the relevant marginal distribution), and subsequently extending this random assignment to all the variables. This has the advantage that it avoids the enumeration of local structures, and in fact achieves a nearly-linear running time. We give a high-level overview of the techniques developed in our
proofs in Section 2. Roughly, our Markov chain is a uniform-block Glauber dynamics which, interestingly, mixes quickly despite the presence of high-degree variables in the random formula. The main point of departure from similar approaches that have been applied to the bounded-degree setting is that we completely circumvent sophisticated coupling arguments that have been used there and which are unfortunately severely constricted by the unbounded degrees in our setting (and made inapplicable). Instead, our main technical contribution is to show that the stationary distribution of our chain is $(c^k \log n)$-spectrally independent for some constant $c \in (0, 1)$, allowing us to apply recently-developed tools in the analysis of Markov chains. Unlike most applications of spectral independence, our proof does not rely on correlation decay (which, as we mentioned, fails to hold for densities exponential in $k$). We show our spectral-independence bounds by relating the probabilistic properties of the solution space with the structure of the formula using coupling techniques, so that we can exploit local sparsity properties of random $k$-SAT.

To formally state our main result, we say that an event $E$ regarding the choice of the random formula $\Phi$ holds with high probability (abbreviated w.h.p.) if $\Pr(E) = 1 - o(1)$ as $n \to \infty$. The total variation distance between two probability distributions $\mu$ and $\nu$ over the same space $\Omega$ is given by $\frac{1}{2} \sum_{x \in \Omega} |\mu(x) - \nu(x)|$ and is denoted by $d_{TV}(\mu, \nu)$. Our main result can now be stated as follows.

**Theorem 1.** For any real $\theta \in (0, 1)$, there is $k_0 \geq 3$ with $k_0 = O(\log(1/\theta))$ such that, for any integers $k \geq k_0$ and $\xi \geq 1$, and for any positive real $\alpha \leq 2^{\theta^{0.039k}}$, the following holds.

There is an efficient algorithm to sample from the satisfying assignments of a random $k$-CNF formula $\Phi = \Phi(k, n, [\alpha n])$ within $n^{-\xi}$ total variation distance of the uniform distribution. The algorithm runs in time $O(n^{1+\theta})$, and succeeds w.h.p. over the choice of $\Phi$.

Using standard techniques from the literature, this $O(n^{1+\theta})$ uniform sampling algorithm can be used to obtain a randomised approximation scheme for counting satisfying assignments of $\Phi$ in time $O(n^{2+\theta}/\varepsilon^2)$, where $\varepsilon$ is the multiplicative error, see [18, Section 7] and Remark 49 for details.

We note here that, independently of this work, Chen, Mani, and Moitra [9] and He, Wu, and Wang [23] obtained sampling algorithms. The approach of [9] is also based on spectral independence but uses a different analysis technique that works up to roughly $2^{k/52}$, whereas the approach of [23] is based on bounding chains and works up to densities roughly equal to $2^{k/3}$.

## 2 Proof outline

Our nearly linear-time sampling algorithm is based on running a Markov chain; this is a standard technique in approximate counting, where typically one runs a Markov chain on the whole state space that converges to the desired distribution. The twist in $k$-SAT is that the state space of the Markov chain needs to be carefully selected in order to avoid certain bottleneck phenomena that impede fast convergence. This approach has been recently applied to bounded-degree $k$-CNF formulas [18, 27, 19, 26] building on the work of Moitra [32] and using the Markov chain known as single-site Glauber dynamics. The main difficulties in all of these works is that the usual distribution properties that are typically used to obtain fast algorithms (such as correlation decay and spatial mixing) fail on the set of all SAT solutions, and in fact even ensuring a connected state space is a major problem. Working around this is one of the main challenges for us too, and in the random $k$-SAT setting it is further aggravated by the fact that a linear number of variables have degrees much higher than average. In fact, w.h.p., a good portion of vertices have degrees depending on $n$ with the maximum degree of the formula scaling as $\log n/\log \log n$.

This poses several new challenges for the Markov chain approach to work in our setting. First of all, we have to ensure that the set of satisfying assignments that our Markov chain considers has good connectivity properties. We address this problem in Section 2.1 of this proof outline, where we find a suitable subset of variables where we can run the Glauber dynamics; this part is inspired by Moitra’s “marking” approach,
though here we need to add an extra layer of marking to facilitate later the analysis of the Markov chain. Second and more importantly, state-of-the-art arguments for bounding the mixing time of the single-site Glauber dynamics on \( k \)-CNF formulas, such as [27, 18] break under the presence of high-degree variables. We focus on this in Section 2.2, where we outline a novel argument that analyses the mixing time of the uniform-block Glauber dynamics using recent advances in spectral independence [3, 29, 4, 7]. This is the first application of the spectral-independence framework for \( k \)-CNF formulas, where the absence of correlation decay limits the application of standard techniques (based on self-avoiding walk trees [4, 7]).

To obtain our spectral-independence bounds we need to combine the probabilistic structure of satisfying assignments with the local sparsity properties of the random formula. The third challenge in our approach is that allows us to do the relevant computations throughout the algorithm’s execution (cf. Section 2.3). Based on these pieces, the full algorithm is presented in Section 2.4.

### 2.1 Marking variables in the random \( k \)-SAT model

In order to ensure good connectivity properties which are essential for fast convergence of the relevant Markov chain, our algorithm runs Glauber dynamics on a large subset \( V_m \) of so-called “marked” variables of the random formula, leaving the rest of the variables unassigned. The variables in \( V_m \) are chosen in a way that ensures that their marginals are near 1/2, which is important for ensuring rapid mixing. Moitra [32] introduced a random “marking” procedure to identify such a subset of variables in the bounded-degree case. The presence of high-degree variables impedes a direct application of this technique in the random-formula setting, but in [21] the authors show that by temporarily removing a small linear number of “bad” clauses that contain high-degree variables one can also achieve marginals near 1/2 for an appropriate set of variables in the random \( k \)-SAT model. Here we further refine these arguments as we need more control over the high-degree variables of the formula in order to conclude rapid mixing of the Glauber dynamics. Recall that the degree of a variable \( v \) is the number of occurrences of literals involving the variable \( v \) in \( \Phi \) and that the maximum degree of the formula \( \Phi \) is the maximum degree among its variables. The following important definitions will be used throughout the paper. We usually use \( V \) to denote the set of variables and \( C \) to denote the set of clauses of a \( k \)-CNF formula \( \Phi \). For any \( c \in C \) we denote by \( \text{var}(c) \) the set of variables appearing in \( c \), and for any \( S \subseteq C \) we denote \( \text{var}(S) = \bigcup_{c \in S} \text{var}(c) \).

**Definition 2** (\( r, r_0, \delta \), high-degree, \( \Delta, \alpha_0 \)). Let \( r := 0.1178, r_0 := 0.117841 \), and \( \delta = 0.00001 \). Let \( k \geq 3 \) be an integer. Let \( \Phi = (V, C) \) be a \( k \)-CNF formula. We say that a variable \( v \in V \) is high-degree if the degree of \( v \) is at least \( \Delta := \lceil 2^{(r_0 - 2\delta)k} \rceil \). Most of our technical results consider random \( k \)-CNF formulas with density at most \( \alpha_0 := 2^{(r_0 - 2\delta)k} / k^3 \).

The bottleneck for the density threshold of Theorem 1 comes from our mixing time results, see Section 2.2. Some of the time we also consider densities \( \alpha \leq 2^{rk} \). The constant \( r \) satisfies \( r < r_0 \), where \( r_0 \) will be relevant when establishing a marking of the variables. We could have chosen any value of \( r \) that is less than \( r_0 \).

We refer to Section 4 for details on our procedure to determine the bad variables/clauses of the formula \( \Phi \). Roughly, bad variables consist of high-degree variables (as in Definition 2), plus those variables that appear in a clause with at least two other bad variables (recursively); bad clauses are those clauses that contain at least three bad variables. We use \( V_{\text{bad}} \) and \( C_{\text{bad}} \) to denote the sets of bad variables and clauses. We use \( V_{\text{good}} = V \setminus V_{\text{bad}} \) to denote the set of good variables, and \( C_{\text{good}} = C \setminus C_{\text{bad}} \) to denote the set of good clauses. The following proposition, proved in Section 4, summarises the main properties of the above sets.
Proposition 3. Let $\Phi = (\mathcal{V}, \mathcal{C})$ be a $k$-CNF formula. For any $c \in \mathcal{C}_{\text{good}}$, we have $|\text{var}(c) \cap \mathcal{V}_{\text{bad}}| \leq 2$, and for any $c \in \mathcal{C}_{\text{bad}}$, we have $|\text{var}(c) \cap \mathcal{V}_{\text{good}}| = 0$. Moreover, every good variable has degree less than $\Delta$. There is a procedure to determine $\mathcal{C}_{\text{bad}}$ that runs in time $O(n + mk)$, where $n$ is the number of variables of $\Phi$ and $m$ is the number of clauses of $\Phi$.

It turns out that, w.h.p. over the choice of $\Phi$, most clauses (and variables) in the random formula $\Phi$ are good, see Lemma 15 for a precise statement. At this stage, it would be natural to try to rework the Markov chain approach of [18]. To do this, we would split the set of good variables in marked variables and control variables in such a way that marked variables have marginals close to $1/2$. Then we run the Glauber dynamics on the set of marked variables. However, as we explain in Section 2.2, the state-of-the-art techniques used to analyse the mixing time of the single-site Glauber dynamics on bounded-degree formulas do not generalise to the random $k$-SAT setting; the main reason for this is that they fail to capture the effect that the high-degree variables have on the marginal probabilities of other variables. Therefore, we need to develop an alternative approach that is robust against the presence of high-degree variables. Our main contribution is an argument to apply the spectral independence framework [7, 8] to the random $k$-SAT model that leads to nearly linear sampling algorithms. To do this, it is important to introduce a third type of good variables, which we call the auxiliary variables. This motivates the following definition of marking.

Definition 4 ($r$-distributed, $r$-marking). Let $r > 0$. Let $\Phi = (\mathcal{V}, \mathcal{C})$ be a $k$-CNF formula and $V$ be a subset of $\mathcal{V}_{\text{good}}$. We say that $V$ is $r$-distributed if for each $c \in \mathcal{C}_{\text{good}}$ we have $|\text{var}(c) \cap V| \geq r(k - 3)$.

An $r$-marking of $\Phi$ is a partition $(\mathcal{V}_m, \mathcal{V}_a, \mathcal{V}_c)$ of the variables of $\Phi$ such that

1. $\mathcal{V}_c$ contains all the bad variables and the set $\mathcal{V}_c \setminus \mathcal{V}_{\text{bad}}$ is $(2r)$-distributed;
2. the sets of good variables $\mathcal{V}_m$ and $\mathcal{V}_a$ are $r$-distributed.

The variables in $\mathcal{V}_m$ are called marked variables, the variables in $\mathcal{V}_a$ are called auxiliary variables, and the variables in $\mathcal{V}_c$ are called control variables.

In Section 5 we show that random $k$-CNF formulas have $r_0$-markings when the density $\alpha$ is below the threshold $\alpha_0 = 2^{(r_0 - 26)k}/k^3$, and that the marginals of marked and auxiliary variables are close to $1/2$; this is where the value of $r_0$ becomes important in the argument. We collect these results in Proposition 6 below; first we give some relevant definitions.

Definition 5 ($\Omega^*$, $\mu_A$, $\Phi^A$, $\mathcal{C}^A$, $\mathcal{V}^A$, $\Omega^A$). Let $\Phi = (\mathcal{V}, \mathcal{C})$ be a $k$-CNF formula. Let $\Omega^*$ be the set of all assignments $\mathcal{V} \rightarrow \{F, T\}$. Given any subset $A \subseteq \Omega^*$, let $\mu_A$ be the uniform distribution on $A$. Let $\Omega$ be the set of satisfying assignments of $\Phi$. For any partial assignment $\Lambda$ we denote by $\Phi^\Lambda$ the formula obtained by simplifying $\Phi$ under $\Lambda$, i.e., removing the clauses which are already satisfied by $\Lambda$, and removing false literals from the remaining clauses. We denote by $\mathcal{C}^A$ and $\mathcal{V}^A$ the sets of clauses and variables of $\Phi^A$. Moreover, we denote by $\Omega^A$ the set of satisfying assignments of $\Phi^A$.

Proposition 6. There is an integer $k_0$ such that for any $k \geq k_0$ and any density $\alpha$ with $\alpha \leq \alpha_0$ the following holds w.h.p. over the choice of the random $k$-CNF formula $\Phi = \Phi(k, n, \lfloor \alpha n \rfloor)$. There exists an $r_0$-marking $(\mathcal{V}_m, \mathcal{V}_a, \mathcal{V}_c)$ of $\Phi$. Moreover, for any such marking, for any $v \in \mathcal{V}_m \cup \mathcal{V}_a$, any $V \subseteq \mathcal{V}_m \cup \mathcal{V}_a$ with $v \notin V$, and any $\Lambda : \mathcal{V} \rightarrow \{F, T\}$, we have

$$\max \left\{ \Pr_{\mu_A} (v \mapsto F), \Pr_{\mu_A} (v \mapsto T) \right\} \leq \frac{1}{2} \exp \left( \frac{1}{k^2 (r_0 + \delta)k} \right).$$

Proof. This follows directly by combining Lemmas 20 and 21, which are stated and proved in Section 5.  \(\square\)
The bound given in Proposition 6 on the marginal probabilities of the marked and auxiliary variables is exploited several times, and we will explain some of these applications in this proof outline. We remark that the bound on the marginals of marked and auxiliary variables holds for any pinning of any subset of these variables, which will be relevant in the spectral independence argument.

**Definition 7 ($\mu|_V$).** Let $V$ be a finite set and let $\Omega \subseteq \{F, T\}^V$. Let $\mu$ be a distribution over $\Omega$. For a set $V \subseteq \mathcal{V}$, we denote by $\mu|_V$ the marginal distribution of $\mu$ on $V$.

Proposition 6 essentially states that the distribution $\mu|_{\mathcal{V}_m \cup \mathcal{V}_a}$ is very close to the uniform distribution over all assignments $\mathcal{V}_m \cup \mathcal{V}_a \rightarrow \{F, T\}$. This concept is formalised in the following definition.

**Definition 8 ($\varepsilon$-uniform).** Let $V$ be a set of variables and $\mu$ be a probability distribution over the assignments $V \rightarrow \{F, T\}$. Let $\Lambda: S \rightarrow \{F, T\}$ be an assignment of some subset of variables $S \subseteq V$. We denote by $\Pr_{\mu}(\Lambda)$ the probability under $\mu$ of the event that the variables in $S$ are assigned values according to $\Lambda$, and by $\Pr_{\mu}(\cdot|\Lambda)$ the corresponding conditional distribution of $\mu$.

For $\varepsilon \in (0, 1)$, we say that the distribution $\mu$ is $\varepsilon$-uniform if for any variable $v \in V$ and any partial assignment $\Lambda: V \setminus \{v\} \rightarrow \{F, T\}$, we have

$$\max \{\Pr_{\mu} (v \mapsto F|\Lambda), \Pr_{\mu}(v \mapsto T|\Lambda)\} \leq 1/2 + \varepsilon.$$

From Proposition 6, it follows that the distribution $\mu|_{\mathcal{V}_m}$ is $\varepsilon$-uniform for $\varepsilon = (2^{-(r_0+\delta)}k/k)$, so for any $\Lambda: \mathcal{V}_m \rightarrow \{F, T\}$, the probability that the assignment of the marked variables is $\Lambda$ is at least $(1 - e^\varepsilon/2)|\mathcal{V}_m|$. The $\varepsilon$-uniform property also (trivially) guarantees that the space of assignments $\Lambda: \mathcal{V}_m \rightarrow \{F, T\}$ with $\Pr_{\mu}(\Lambda) > 0$ is connected via single-variable updates, so we can indeed consider the Glauber dynamics over $\mathcal{V}_m$. This leads to the main challenge of this work: does this chain mix rapidly?

### 2.2 Mixing time of the Glauber dynamics on the marked variables

Recently, there has been significant progress in showing that the single-variable Glauber dynamics on appropriately chosen subsets of variables mixes quickly for $k$-CNF formulas with bounded degree [18, 26]. These approaches carefully execute a union bound over paths of clauses connecting marked variables in order to bound the coupling time between two copies of the chain. However, these union bound arguments break under the presence of high-degree variables that are present in random $k$-SAT; this is because the number of paths connecting marked variables is very sensitive to the max degree of the formula and in particular grows too fast in our setting. We give a more detailed discussion in Section 8.1.

Instead, we apply the spectral independence framework to show rapid mixing of a uniform-block Glauber dynamics, which we review briefly below. Applications of spectral independence usually exploit decay of correlations to show that the spectral independence condition holds, see [4, 7, 5] for examples. As we have mentioned in the introduction, correlation decay fails to hold for densities exponential in $k$ in the random $k$-SAT model [33] and therefore, we have to develop a different approach to conclude that the spectral-independence condition holds in our setting. This is our main contribution in this work; we show that the marginal distribution on the marked variables, i.e., $\mu|_{\mathcal{V}_m}$, is $(\epsilon \log n)$-spectrally independent for some $\epsilon > 0$ that can be made arbitrarily small for sufficiently large $k$. Our argument builds on the coupling idea of Moitra [32] (as refined in [21] for random $k$-SAT) and relates the spectral independence condition to the expected number of failed clauses in this coupling process. This allows us to exploit the local sparsity properties of the random $k$-SAT model to analyse the mixing time of the Glauber dynamics.

A caveat here is that the spectral independence of $\mu|_{\mathcal{V}_m}$ is not enough on its own to conclude fast mixing of the single-site Glauber dynamics. The most direct way to work around this is to analyse instead the so-called $\rho$-uniform-block Glauber dynamics that updates $\rho$ vertices at a time for some $\rho$ that scales...
linearly in \( n \); the main missing ingredient there is to show that the modified chain can be implemented efficiently which we discuss in Section 2.3. We next give a quick overview of the relevant ingredients of the spectral-independence literature that we will need.

### 2.2.1 The \( \rho \)-uniform-block Glauber dynamics, spectral independence, and the mixing time

Let \( V \) be a finite set of size \( M \) and \( \mu \) be a distribution over the assignments \( V \to \{F, T\} \). Let \( \Omega \) be the set of assignments \( V \to \{F, T\} \) with positive probability under \( \mu \). For an integer \( \rho \in \{1, 2, \ldots, |V|\} \), the \( \rho \)-uniform-block Glauber dynamics for \( \mu \) is a Markov chain \( X_t \) where \( X_0 \in \Omega \) is an arbitrary configuration and, for \( t \geq 1 \), \( X_t \) is obtained from \( X_{t-1} \) by first picking a subset \( S \subseteq V \) of size \( \rho \) uniformly at random, letting \( \Lambda_t \) be the restriction of \( X_t \) to \( V \setminus S \), and updating the configuration on \( S \) according to the probability distribution \( \mu(\cdot|\Lambda_t) \). This chain satisfies the detailed balance equation for \( \mu \). Hence, when the chain is irreducible, for \( \varepsilon > 0 \), we can consider its mixing time \( T_{\text{mix}}(\rho, \varepsilon) = \max_{\sigma \in \Omega} \min\{t : d_{TV}(X_t, \mu) \leq \varepsilon \mid X_0 = \sigma\} \). We say that \( \mu \) is \( b \)-marginally bounded if for all \( v \in V \), \( S \subseteq V \setminus \{v\}, \Lambda : S \to \{F, T\} \) with \( \Pr_\mu(\Lambda) > 0 \), and \( \omega \in \{F, T\} \), it either holds that \( \Pr_\mu(v \mapsto \omega|\Lambda) = 0 \) or \( \Pr_\mu(v \mapsto \omega|\Lambda) \geq b \). Spectral independence results have recently been used in the \( b \)-marginally bounded setting to obtain fast mixing time of the uniform-block Glauber dynamics \([6, 8]\). For \( S \subseteq V \), \( \Lambda : S \to \{F, T\} \) with \( \Pr_\mu(\Lambda) > 0 \), and \( u, v \in V \) with \( u \notin S \) and \( 0 < \Pr_\mu(u \mapsto \Lambda|S) < 1 \), the influence of \( u \) on \( v \) (under \( \mu \) and \( \Lambda \)) is defined as

\[
I^\Lambda(u \to v) = \Pr_\mu(v \mapsto \Lambda|u \mapsto \Lambda) - \Pr_\mu(v \mapsto \Lambda|u \mapsto F, \Lambda). \tag{1}
\]

The influence matrix conditioned on \( \Lambda \) is the (two-dimensional) matrix whose entries consist of \( I^\Lambda(u \to v) \) over all relevant \( u \) and \( v \). We denote by \( I^\Lambda \) the matrix and by \( \lambda_1(I^\Lambda) \) its largest eigenvalue in absolute value. For a real \( \eta > 0 \), we say that \( \mu \) is \( \eta \)-spectrally independent if for all \( S \subseteq V \) and \( \Lambda : S \to \{F, T\} \) with \( \Pr_\mu(\Lambda) > 0 \) we have \( \lambda_1(I^\Lambda) \leq \eta \). From the results of \([8]\), one can conclude the following bound for the mixing time of the uniform-block Glauber dynamics, see Appendix B for details.

**Lemma 9.** The following holds for any reals \( b, \eta > 0 \), any \( \kappa \in (0, 1) \) and any integer \( M \) with \( M \geq 2^5(4\eta/b^2 + 1) \). Let \( V \) be a set of size \( M \), let \( \mu \) be a distribution over the assignments \( V \to \{F, T\} \), let \( \Omega = \{\Lambda : V \to \{F, T\} : \mu(\Lambda) > 0\} \) and let \( \mu_{\text{min}} = \min_{\Lambda \in \Omega} \mu(\Lambda) \). If \( \mu \) is \( b \)-marginally bounded and \( \eta \)-spectrally independent, then, for \( \rho = \lceil \kappa M \rceil \) and \( C_\rho = (2/\kappa)^{\eta/\kappa^2 + 1} \), we have

\[
T_{\text{mix}}(\rho, \varepsilon) \leq \left[C_\rho \frac{M}{\rho} \left( \log \log \frac{1}{\mu_{\text{min}}} + \log \frac{1}{2\varepsilon^2} \right) \right].
\]

We are going to consider the uniform-block Glauber dynamics on the marked variables of \( \Phi \), so \( V = V_m \), and the set of states coincides with the set of assignments \( V_m \to \{F, T\} \) as all of them have positive probability. In this setting, the target distribution is \( \mu_\Omega|_{V_m} \). The distribution \( \mu_\Omega|_{V_m} \) is \((1/\varepsilon)\)-marginally-bounded as a straightforward consequence of the fact that it is \((1/k)\)-uniform, see Remark 47 for details. Hence, in order to conclude rapid mixing it remains to establish spectral independence. For this, we are going to use the well-known fact (see for instance \([7]\)) that, for \( S \subseteq V \) and \( \Lambda : S \to \{F, T\} \), we have

\[
\lambda_1(I^\Lambda) \leq \max_{u \in V \setminus S} \sum_{v \in V \setminus S} |I^\Lambda(u \to v)|. \tag{2}
\]

### 2.2.2 Spectral independence in the random \( k \)-SAT model

In this section we state our spectral independence results in the random \( k \)-SAT model. The results stated in this section are proved in Section 8. Our main technical result is the following.
Lemma 10. There is an integer $k_0 \geq 3$ such that for any integer $k \geq k_0$ and any density $\alpha$ with $\alpha \leq 2^{r_0 k/3}/k^3$ the following holds. W.h.p., over the choice of the random $k$-CNF formula $\Phi = \Phi(k, n, [\alpha n])$, for any $r_0$-marking $(V_m, V_a, V_c)$ of $\Phi$, the distribution $\mu|_{V_m}$ is $(2^{-r_0 k} \log n)$-spectrally independent.

We are going to describe some of the ideas behind the proof of Lemma 10. First, we highlight the fact that, due to the presence of high-degree variables (which form logarithmically-sized connected components), it is hard to conclude $\eta$-spectral independence with $\eta = O(1)$. This has also been the case in recent work on 2-spin systems on random graphs [5], where instead correlation decay is exploited to prove $\eta$-spectral independence for some $\eta = o(\log n)$. Here, our $\eta$-spectral independence bound for $\eta = o_k(\log n)$ will be based on an appropriate coupling. Note, in light of Lemma 9, $\eta = O(\log n)$ is good enough for proving polynomial mixing time of the uniform-block Glauber dynamics, but we need the improved bound of Lemma 10 in order to conclude the following fast mixing-time result from Lemma 9 (see Section 8). We remark that the more restrictive density threshold $\alpha \leq 2^{r_0 k/3}/k^3$ in the statement of Lemma 10 arises in the union bound given in the proof of this lemma, and that for large enough $k$ we have $2^{0.039k} \leq 2^{r_0 k/3}/k^3$. We can now state our mixing time result.

Lemma 11. There is a function $k_0(\theta) = \Theta(\log(1/\theta))$ such that, for any $\theta \in (0, 1)$, for any integer $k \geq k_0(\theta)$ and any density $\alpha$ with $\alpha \leq 2^{0.039k}$ the following holds. W.h.p., over the choice of the random $k$-CNF formula $\Phi = \Phi(k, n, [\alpha n])$, for any $r_0$-marking $(V_m, V_a, V_c)$ of $\Phi$ and for $\rho = \lfloor 2^{-k-1}|V_m| \rfloor$, the $\rho$-uniform-block Glauber dynamics for updating the marked variables has mixing time $T_{\text{mix}}(\rho, \varepsilon/2) \leq T := 2^{2k+3+3n\theta} \log n$.\[\]

Lemma 11 is stated for the block size $\rho = \lfloor 2^{-k-1}|V_m| \rfloor$, but it could be proved more generally when $\rho = c|V_m|$ and $c \in (0, 1)$. The fact that $\rho \leq |V_m|/2^k$ in the statement will be relevant in implementing efficiently the dynamics, discussed in Section 2.3.

Our approach to prove $\eta$-spectral independence significantly differs from those that in two-spin systems, where it is enough to study sum of influences over trees (thanks to the tree of self-avoiding walks) and exploit decay of correlations in this setting (very roughly, the further away two vertices are in the tree, the smaller the influence that one vertex has in the other). Here we relate influences to the structure of the dependency graph $G_\Phi$ by running a coupling process on the auxiliary variables, and we state this connection in the upcoming Lemma 38. First we define more formally dependency graph $G_\Phi$.

Definition 12 ($G_\Phi$). Let $\Phi = (\mathcal{V}, \mathcal{C})$ be a $k$-CNF formula. We define the graph $G_\Phi$ as follows. The vertex set of $G_\Phi$ is $\mathcal{C}$ and two clauses $c_1$ and $c_2$ are adjacent if and only if $\text{var}(c_1) \cap \text{var}(c_2) \neq \emptyset$. A set $C \subseteq \mathcal{C}$ is connected if $C$ is connected in the graph $G_\Phi$. We say that two variables $u$ and $v$ are connected in $\Phi$ if there is a path $c_1, c_2, \ldots, c_\ell$ in $G_\Phi$ with $u \in \text{var}(c_1)$ and $v \in \text{var}(c_\ell)$.

One of the key ideas behind our analysis is exploiting the fact that, in the random $k$-SAT model, w.h.p. over the choice of the random formula $\Phi$, any logarithmic-sized set of clauses $Y$ that is connected in $G_\Phi$ has constant tree-excess, that is, the number of edges connecting a pair of clauses in $Y$ is $|Y| + O(1)$. This saves a factor of $\Delta$ in the spectral independence bound by ensuring that there is a large independent set of clauses in $Y$. We also obtain improved analysis by restricting the coupling process to auxiliary variables. This enables us to get exponentially small bounds (in $k$) on the influences between marked variables.

2.3 Analysis of the connected components of $\Phi^A$

In this section we deal with the third challenge mentioned at the beginning of Section 2: can we determine the transition probabilities of the Glauber dynamics so that we can actually simulate this Markov chain? In fact, simulating the single-site Glauber dynamics on the marked variables was one of the main challenges even in the bounded-degree case. In that case this was resolved using a method that is restricted to the
bounded-degree setting (and whose bottleneck is the analysis of a rejection sampling procedure). A different procedure is required for the random $k$-SAT setting.

One of the key ideas to simulate this chain is starting the chain on an assignment $X_0 : \mathcal{V}_m \to \{F, T\}$ drawn from the uniform distribution over all assignments of $\mathcal{V}_m$. Since the distribution $\mu_{\Phi}|_{\mathcal{V}_m}$ is $(1/k)$-uniform (Proposition 6), the transition probabilities of the Glauber dynamics are close to uniform. This allows us to show that the probability distribution of the assignment $X_t$ that is output by the uniform-block Glauber dynamics after $t$ steps is also $(1/k)$-uniform (Corollary 22), which will be important in what follows.

In order to run the $\rho$-uniform-block Glauber dynamics we need to be able to sample from the distribution $\mu_{\Phi, \Lambda}$ for any set $S \subseteq \mathcal{V}_m$ with $|S| = \rho$ and any assignment $\Lambda : \mathcal{V}_m \setminus S \to \{F, T\}$ that arises. Unless we can restrict $\Lambda$, sampling from $\mu_{\Phi, \Lambda}$ could potentially be as hard as sampling from $\mu_{\Phi}$. Fortunately for us, the assignment $\Lambda$ is not completely arbitrary; $\Lambda$ is determined by the random choice of $S$ and the current state of the Glauber dynamics (which follows a $(1/k)$-uniform distribution as discussed above). We show that we can efficiently sample from $\mu_{\Phi, \Lambda}$ w.h.p. over the choice of $\Lambda$. An important observation is that we can efficiently sample from $\mu_{\Phi, \Lambda}$ when the connected components of $G_{\phi, \Lambda}$ are logarithmic in size, for example, by applying brute force. This raises the following question: does $G_{\phi, \Lambda}$ break into small connected components w.h.p. over the choice of $\Lambda$? Lemma 13 gives a positive answer when $0 \leq \rho \leq |V|/2^k$. Here the reader can see $V$ as the set of marked variables. The proof of Lemma 13 exploits sparsity properties of logarithmic-sized connected sets of clauses in random formulas in conjunction with the fact that $\mu$ is $(1/k)$-uniform.

**Lemma 13.** There is an integer $k_0 \geq 3$ such that, for any integer $k \geq k_0$, any density $\alpha \leq 2^{rk}$, and any real number $b$ with $a := 2k^4 < b$, the following holds w.h.p. over the choice of $\Phi = \Phi(k, n, \lceil \alpha n \rceil)$.

Let $L$ be an integer satisfying $a \log n \leq L \leq b \log n$. Let $V$ be a set of good variables of $\Phi$ that is $r_0$-distributed, let $\mu$ be a $(1/k)$-uniform distribution over the assignments $V \to \{F, T\}$, and let $\rho$ be an integer with $0 \leq \rho \leq |V|/2^k$. Consider the following experiment. First, draw $S \subseteq V$ from the uniform distribution $\tau$ over subsets of $V$ with size $\rho$. Then, sample an assignment $\Lambda$ from $\mu|_{V \setminus S}$. Denote by $F$ the event that that there is a connected set of clauses $Y$ of $\Phi$ with $|Y| \geq L$ such that all clauses in $Y$ are unsatisfied by $\Lambda$. Then

$$\Pr_{S \sim \tau} \left( \Pr_{\Lambda \sim \mu|_{V \setminus S}} (F) \leq 2^{-\delta k L} \right) \leq 1 - 2^{-\delta k L}.$$  

**Proof sketch.** The proof is in Section 6. For the sake of exposition, we first sketch the proof in the case $\rho = 0$, where the conclusion in the statement reads $\Pr_{\Lambda \sim \mu|_V} (F) \leq 2^{-\delta k L}$. At the end of this proof sketch we explain how we extend the proof to any $\rho$ with $0 \leq \rho \leq |V|/2^k$.

The first step is exploiting local sparsity properties of random $k$-CNF formulas to find many variables from $V$ in any sufficiently large connected set of clauses. Our sparsity results hold for connected sets of clauses with size at least $2k^4 \log n$, and let us conclude the following result (stated as Lemma 26 in Section 6): w.h.p. over the choice of $\Phi$, for every connected set of clauses $Z \subseteq C$ we have

$$\text{if } 2k^4 \log(n) \leq |Z| \leq b \log(n), \text{ then } |\text{var}(Z) \cap V| \geq (r_0 - \delta)k|Z|. \tag{3}$$

The proof of Lemma 26 counts the variables from $V$ in $Z$ by using the fact that $Z$ does not contain many bad clauses and the fact that there are not many edges joining clauses in $Z$. In fact, for such a set $Z$, we show that the number of edges is of order $|Z| + O(1)$, that is, $Z$ has constant tree-excess (Lemma 24). We also need the following result on random $k$-CNF formulas. For each clause $c \in C$, let $Z(c, L) = \{Z \subseteq C : c \in Z, Z \text{ is connected in } G_{\phi}, |Z| = L\}$. Then, w.h.p. over the choice of $\Phi$, [21, Lemma 40] shows that, as long as $L \geq \log n$,

$$\text{for any clause } c \in C \text{ we have } |Z(c, L)| \leq (9k^2 \alpha)^L. \tag{4}$$

Once we have established (3) and (4), the proof exploits the fact that $\mu$ is close to the uniform distribution. First, we introduce some notation. Let $L$ be an integer with $a \log n \leq L \leq b \log n$. Let $S = \emptyset$ as we
are dealing with the case $\rho = 0$. For $c \in \mathcal{C}$ and $Z \in \mathcal{Z}(c, L)$, we denote by $\mathcal{E}_1(Z, S)$ the event that $Z \subseteq C^\Lambda$, where $\Lambda$ is drawn from $\mu |_{V \setminus S}$, see Definition 7. We keep track of $S$ in the notation here as this is relevant in the general case. Recall that $Z \subseteq C^\Lambda$ means that none of the clauses in $Z$ are satisfied by the assignment $\Lambda$ (Definition 5). The first observation is that the event $\mathcal{F}$ from the statement satisfies $\mathcal{F} = \bigcup_{c \in \mathcal{C}, Z \in \mathcal{Z}(c, L)} \mathcal{E}_1(Z, S)$. We then claim that for any $c \in \mathcal{C}$ and $Z \in \mathcal{Z}(c, L)$ we have

$$\Pr_{\Lambda \sim \mu |_{V \setminus S}}(\mathcal{E}_1(Z, S)) \leq \frac{2^{-\delta kL}}{|\mathcal{C}| \cdot |\mathcal{Z}(c, L)|},$$

(5)

so the result would follow from a union bound over $c$ and $Z$. Let us give some insight on how we prove (5). Let $c \in \mathcal{C}$ and $Z \in \mathcal{Z}(c, L)$. The main idea is that, if all clauses in $Z$ are unsatisfied by $\Lambda$ then, when we sampled $\Lambda \sim \mu |_{V \setminus S}$, for each variable $v$ in $\var(Z) \cap (V \setminus S)$ we picked the value that does not satisfy the clauses of $Z$ containing $v$. Thus, we can bound the probability that all clauses in $Z$ are unsatisfied as a product, over the variables in $\var(Z) \cap (V \setminus S)$, of probabilities, each factor corresponding to the probability that a variable is assigned a certain value (under some careful conditioning, see the proof in Section 6 for details). Since the distribution $\mu$ is $(1/k)$-uniform, each one of these factors can be bounded by $\exp(1/k)/2$, obtaining

$$\Pr_{\Lambda \sim \mu |_{V \setminus S}}(\mathcal{E}_1(Z, S)) \leq \left(\frac{1}{2} \exp \left(\frac{1}{k}\right)\right)^{|\var(Z) \cap (V \setminus S)|}.$$  

(6)

In (3) we gave a lower bound on $|\var(Z) \cap V|$, which can be applied in conjunction with (4) to conclude, after some calculations, that the bound given in (5) holds.

The case $\rho > 0$ is more technical and one has to be more careful in these calculations. We show that (5) holds when $S$ does not contain many variables in $\var(Z) \cap V$. A slightly different argument is needed when going from (6) to (5); here we have to bound $|\var(Z) \cap (V \setminus S)|$ instead of $|\var(Z) \cap V|$. It turns out that, as long as the bound $|\var(Z) \cap V \setminus S| \leq |\var(Z) \cap V|/k$ holds, the calculations to go from (6) to (5) also hold in this setting. Finally, we show that the probability that $|\var(Z) \cap V \setminus S| \leq |\var(Z) \cap V|/k$ occurs when picking $S$ is at least $1 - 2^{\delta kL}$. The proof of this fact is purely combinatorial, and requires the hypothesis $\rho \leq |V|/2^k$, see Section 6 for details.

Once we have established Lemma 13, we can use it to implement the $\rho$-uniform-block Glauber dynamics on the marked variables for $0 < \rho \leq |V_m|$ and complete our sampling algorithm, which we explicitly state in Section 2.4.

### 2.4 The sampling algorithm

To complete this proof outline, we explicitly describe Algorithm 1, our algorithm for sampling satisfying assignments of $k$-CNF formulas. The algorithm uses a method $\text{Sample}(\Phi^\Lambda, S)$ to sample an assignment $\tau : S \rightarrow \{F, T\}$ from the distribution $\mu |_{\Omega^\Lambda | S}$. This method exploits the fact that logarithmic-sized connected set of clauses have constant tree-excess, which does not hold in the bounded-degree case. This tree-like property enables us to efficiently sample satisfying assignments on the connected components of $\Phi^\Lambda$ by a standard dynamic programming argument, see Section 7. Lemma 14 is our main result on $\text{Sample}(\Phi^\Lambda, S)$.

**Lemma 14.** There is an integer $k_0 \geq 3$ such that, for any integers $k \geq k_0$, $\xi \geq 1$ and any density $\alpha \leq 2^{-k}$, the following holds w.h.p. over the choice of $\Phi = \Phi(k, n, \lceil \alpha n \rceil)$. Let $V$ be a subset of variables and let $\Lambda : V \rightarrow \{F, T\}$ be a partial assignment such that all the connected components in $G_{\Phi^\Lambda}$ have size at most $2k^4(1 + \xi) \log(n)$. Then, there is an algorithm that, for any $S \subseteq V \setminus V$, samples an assignment from $\mu |_{\Omega^\Lambda | S}$ in time $O(|S| \log n)$.
The method Sample($\Phi^\Lambda, S$) is used in Algorithm 1 to implement each step of the $\rho$-uniform-block Glauber dynamics on the marked variables. It is also used to extend the assignment of marked variables computed by the Glauber dynamics to a satisfying assignment of $\Phi$. As a design choice, this method returns error when the connected components of $G_{\Phi^\Lambda}$ have size larger than $2k^4(1 + \xi) \log(n)$. We remark that the probability that Sample($\Phi^\Lambda, S$) returns error is very small when running the Glauber dynamics thanks to Lemma 13. We can now introduce Algorithm 1, which has two parameters $\theta \in (0, 1)$ and $\xi \geq 1$ as in Theorem 1.

**Algorithm 1** The approximate sampling algorithm for satisfying assignments of random $k$-CNF formulas.

**Input:** A $k$-CNF formula $\Phi = (V, C)$ with $n$ variables

1: Compute the sets of bad/good variables and bad/good clauses for $\Phi$ as in Proposition 3.
2: Let $\varepsilon = n^{-\xi}$. Compute a marking $(\mathcal{V}_m, \mathcal{V}_a, \mathcal{V}_c)$ for $\Phi$ as in Lemma 20 with $p = \varepsilon/4$. This succeeds with probability at least $1 - \varepsilon/4$. If this does not succeed, the algorithm returns error.
3: For each $v \in \mathcal{V}_m$, sample $X_0(v) \in \{F, T\}$ uniformly at random.
4: for $t$ from 1 to $T := \lceil 2^{2k+3}n^\theta \log \frac{2n}{\varepsilon^2} \rceil$ do
5: Choose uniformly at random a set of marked variables $S \subseteq \mathcal{V}_m$ with size $\rho := \lceil 2^{-k-1}|\mathcal{V}_m| \rceil$.
6: Let $\Lambda_t$ be the assignment $X_{t-1}$ restricted to $\mathcal{V}_m \setminus S$.
7: $Y \leftarrow $ Sample($\Phi^{\Lambda_t}, S$).
8: $X_t \leftarrow \Lambda_t \cup Y$.
9: end for
10: $Y \leftarrow $ Sample($\Phi^{X_T}, \mathcal{V}_a \cup \mathcal{V}_c$).
11: return $X_T \cup Y$.

We remark here that Algorithm 1 only works for large enough $k$, and this hypothesis will be used several times in our arguments. The quantity $T$ defined in this algorithm corresponds to the mixing time of the $\rho$-uniform-block Glauber dynamics given in Lemma 11.

3 Paper outline

The rest of this work is organised as follows. In Section 4 we introduce the procedure for determining bad clauses. In Section 5 we prove Proposition 6 on markings of random formulas. In Section 6 we prove our technical result on the connected components of $\Phi^\Lambda$, Lemma 13. In Section 7 we give the method Sample and prove Lemma 14. In Section 8 we prove the results on spectral independence stated in Section 2.2 of the proof outline. Finally, in Section 9 we complete the proof of Theorem 1 by combining our mixing time results (Lemma 11), our algorithm to sample from small connected components (Lemma 14) and our result on the size of the connected components of $\Phi^\Lambda$ (Lemma 13).

To help keep track of the notation and definitions introduced in this work, the reader is referred to the tables in Appendix C.

4 High-degree and bad variables in random CNF formulas

As we noted in the introduction, one of the keys to sampling satisfying assignments in the unbounded-degree setting is to “sacrifice” a few variables per clause (treating them separately in the sampling algorithm) and to (temporarily) remove a small linear number of clauses that contain these. The point of this is to ensure that the remaining (“good”) clauses have mostly low-degree variables (at most two bad ones) and also that the rest of the clauses (the “bad” ones) form small connected components that interact with the good clauses in a manageable way.
Recall that high-degree variables were introduced in Definition 2. By standard arguments about random graphs, one can determine that, w.h.p. over the choice of \( \Phi \), the number of high-degree variables of \( \Phi \) is bounded. We want to identify the clauses of \( \Phi \) that have at most 2 high-degree variables, since clauses with a lot of high-degree variables will interfere with our sampling algorithms. This motivates the following construction. The bad variables and bad clauses of \( \Phi \) are identified by running the process given in Algorithm 2. Here \( V_{bad} \) denotes the set of bad variables and \( C_{bad} \) denotes the set of bad clauses.

Algorithm 2 Computing bad variables and bad clauses

Input: A k-CNF formula \( \Phi = (\mathcal{V}, \mathcal{C}) \)
1: \( V_0 \leftarrow \) the set of high-degree variables
2: \( C_0 \leftarrow \) the set of clauses with at least 3 variables in \( V_0 \)
3: \( i \leftarrow 0 \)
4: while \( i = 0 \) or \( V_i \neq V_{i-1} \) do
   5: \( i \leftarrow i + 1 \)
   6: \( V_i \leftarrow V_{i-1} \cup \text{var}(C_{i-1}) \)
   7: \( C_i \leftarrow \{ c \in \mathcal{C} : |\text{var}(c) \cap V_i| \geq 3 \} \)
8: end while
9: \( C_{bad} \leftarrow C_t \) and \( V_{bad} \leftarrow V_i \)
10: return \( V_{bad}, C_{bad} \)

We define the good clauses of \( \Phi \) as \( C_{good} = \mathcal{C} \setminus C_{bad} \) and the good variables of \( \Phi \) as \( V_{good} = \mathcal{V} \setminus V_{bad} \). We will use the observations given in Proposition 3 several times in this work.

**Proposition 3.** Let \( \Phi = (\mathcal{V}, \mathcal{C}) \) be a k-CNF formula. For any \( c \in C_{good} \), we have \( |\text{var}(c) \cap V_{bad}| \leq 2 \), and for any \( c \in C_{bad} \), we have \( |\text{var}(c) \cap V_{good}| = 0 \). Moreover, every good variable has degree less than \( \Delta \). There is a procedure to determine \( C_{bad} \) that runs in time \( O(n + mk) \), where \( n \) is the number of variables of \( \Phi \) and \( m \) is the number of clauses of \( \Phi \).

**Proof.** In this proof we briefly explain the implementation of Algorithm 2 announced in the statement. First, for each clause \( c \) we keep track of the number of bad variables in \( \text{var}(c) \), denoted \( \text{bad}(c) \). We also have a stack of of bad variables \( S_V \) that are yet to be processed by the algorithm. At the start of the algorithm, we set \( S_V \leftarrow V_0 \). While \( S_V \) is non-empty, we take the variable \( v \) on the top of the stack and increase \( \text{bad}(c') \) by 1 for those clauses \( c' \) where \( v \) appears. If any of these updates gives \( \text{bad}(c') \geq 3 \), we add \( \text{var}(c') \) to the stack \( S_V \), set the variables in \( \text{var}(c') \) as bad and set the clause \( c' \) as bad. At the end of this process, \( S_V \) is empty and we have found all the bad variables and bad clauses of \( \Phi \). As every variable is added to the stack at most once and the list \( \text{bad}(-) \) is updated at most \( mk \) times (once per literal in \( \Phi \)), the running time is \( O(n + mk) \).

In our work we need a variation of a result of [21] that controls the number of bad clauses in connected subgraphs of \( G_\Phi \). We state this result in Lemma 15 and prove it in Appendix A.

**Lemma 15** (Modified version of [21, Lemma 8.16]). There is an integer \( k_0 \geq 3 \) such that for any integer \( k \geq k_0 \) and any density \( \alpha \leq \alpha_0 = 2^{(k_0-2k)/k^3} \), the following holds w.h.p. over the choice of the random k-CNF formula \( \Phi = \Phi(k, n, \lfloor \alpha n \rfloor) \). For every connected set of clauses \( Y \) in \( G_\Phi \) such that \( |\text{var}(Y)| \geq 2k^4 \log n \), we have \( |Y \cap C_{bad}| \leq |Y|/k \).

Lemma 15 guarantees that, w.h.p. over the choice of \( \Phi \), bad clauses are a minority among all the clauses of \( \Phi \). This will be used to show that bad clauses do not affect significantly the behaviour of our sampling algorithm. We point out that the definitions of \( V_{good}, V_{bad}, C_{good} \) and \( C_{bad} \) given in [21] use the condition
A property that is useful for sampling satisfying assignments is having a high proportion of variables in each good clause such that the marginals of these variables are fairly close to $1/2$. That is, having variables which are roughly equally likely to be true or false in a random satisfying assignment. The marginals of high-degree variables do vary. However, even in the random $k$-SAT model it turns out that there are enough variables with marginals near $1/2$. Following the basic approach of Moitra [32], we partition the good variables of a random $k$-CNF formula into types. Here we have three type of variables (instead of two): marked, auxiliary and control variables. The high-level goal is to do this in such a way that each clause has a good proportion of each one of these types of variables. We call this construction a marking, see Definition 4 of the proof outline for the precise definition. For such marking, we will show that as long as the control variables are left unassigned/unpinned, the marginals of the marked and auxiliary variables are all near $1/2$ as a consequence the Lovász local lemma [17]. We first set up the notation and results that we need.

It is not difficult to show that in the random $k$-SAT model, w.h.p. over the choice of the formula $\Phi$, two distinct clauses share at most $k/2$ variables with marginals near $1$. Following the basic approach of Moitra [32], we partition the good variables of a random $k$-CNF formula into types. Here we have three type of variables (instead of two): marked, auxiliary and control variables. The high-level goal is to do this in such a way that each clause has a good proportion of each one of these types of variables. We call this construction a marking, see Definition 4 of the proof outline for the precise definition. For such marking, we will show that as long as the control variables are left unassigned/unpinned, the marginals of the marked and auxiliary variables are all near $1/2$ as a consequence the Lovász local lemma [17]. We first set up the notation and results that we need.

5 Identifying a set of “marked” variables with good marginals

A property that is useful for sampling satisfying assignments is having a high proportion of variables in each good clause such that the marginals of these variables are fairly close to $1/2$. That is, having variables which are roughly equally likely to be true or false in a random satisfying assignment. The marginals of high-degree variables do vary. However, even in the random $k$-SAT model it turns out that there are enough variables with marginals near $1/2$. Following the basic approach of Moitra [32], we partition the good variables of a random $k$-CNF formula into types. Here we have three type of variables (instead of two): marked, auxiliary and control variables. The high-level goal is to do this in such a way that each clause has a good proportion of each one of these types of variables. We call this construction a marking, see Definition 4 of the proof outline for the precise definition. For such marking, we will show that as long as the control variables are left unassigned/unpinned, the marginals of the marked and auxiliary variables are all near $1/2$ as a consequence the Lovász local lemma [17]. We first set up the notation and results that we need.

Lemma 16. For any $k \geq 3$ and any density $\alpha > 0$ (possibly depending on $k$), the following holds w.h.p. over the choice of the random $k$-CNF formula $\Phi = \Phi(k, n, [\alpha n])$. We have $|\text{var}(c)| \geq k - 1$ and $|\text{var}(c) \cap \text{var}(c')| \leq 2$ for all $c, c' \in C$ with $c \neq c'$.

Proof. First, let us prove that, for $k \geq 3$, w.h.p. over the choice of $\Phi$, $|\text{var}(c)| \geq k - 1$ for all $c \in C$. Let us denote by $R_c$ the event that a clause $c$ has at least two repetitions among its variables, that is, $|\text{var}(c)| \leq k - 2$. We claim that $\Pr(R_c) \leq q(k)/n^2$, where $q(k) = \binom{k}{3} + k(k - 1)(k - 2)(k - 3)/4$. To prove this statement we note that the probability that a variable appears at least 3 times in $c$ is at most $\binom{k}{3}n^{k-2}/n^k$, and the probability that two distinct variables are repeated in $c$ is at most $p(k)n(n-1)n^{k-4}/n^k$ for $p(k) = k(k - 1)(k - 2)(k - 3)/4$. Hence, by adding up both cases, we find that $\Pr(R_c) \leq q(k)/n^2$, and $\Pr(\bigcup_{c \in C} R_c) \leq q(k)m/n^2 \leq q(k)/n = O(1/n)$, so the result follows.

Let $c, c' \in C$ with $c \neq c'$. We study $|\text{var}(c) \cap \text{var}(c')|$, $\Pr(|\text{var}(c) \cap \text{var}(c')| \geq 3) \leq n(n-1)(n-2)n^2(k-3)(k-1)(k-2)2^{k^2}/n^2k^2 \leq k^6/n^3$. Therefore, the probability that there is a pair of clauses $c, c'$ with $|\text{var}(c) \cap \text{var}(c')| \geq 3$ is bounded from above by $m(m-1)/2 \leq m^2/2 \leq q^2/k^2 = O(1/n)$, which finishes the proof. 

We will use the asymmetric version of the Lovász local lemma (LLL), proved by Lovász and originally published in [38]. Before stating this result, let us introduce some notation. Let $P$ be a finite collection of mutually independent random variables. Let $B$ an event that is a function of the random variables in $P$. Let $\mathcal{A}$ be a collection of events that are a function of the random variables in $P$. We define $\Gamma(B)$ as the set of events $A \in \mathcal{A}$ such that $A \neq B$ and $A$ and $B$ are not independent. In this setting, $\Pr_P(B)$ is the probability that the event $B$ holds when sampling all the random variables in $P$. 

Theorem 17 (Asymmetric Lovász local lemma, [22, Theorems 1.1 and 2.1]). Let \( \mathcal{P} \) be a finite collection of mutually independent random variables. Let \( \mathcal{A} \) be a collection of events that are a function of the random variables in \( \mathcal{P} \). If there exists a function \( x : \mathcal{A} \to (0,1) \) such that, for all \( A \in \mathcal{A} \), we have

\[
\Pr_{\mathcal{P}}(A) \leq x(A) \prod_{N \in \Gamma(A)} (1 - x(N)),
\]

then \( \Pr_{\mathcal{P}}(\bigcap_{A \in \mathcal{A}} \overline{A}) > 0 \). Furthermore, for any event \( B \) that is a function of the random variables in \( \mathcal{P} \), we have

\[
\Pr_{\mathcal{P}}(B \big| \bigcap_{A \in \mathcal{A}} \overline{A}) \leq \Pr_{\mathcal{P}}(B) \prod_{A \in \Gamma(B)} (1 - x(A))^{-1}.
\]

We are going to apply the LLL in Lemma 20 to find an \( r_0 \)-marking of \( \Phi \) (Definition 4), w.h.p. over the choice of the random formula, for some appropriate \( r_0 \in (0,1) \). Before proving Lemma 20, let us highlight how strong the properties of an \( r \)-marking are. First, the fact that a set of marked variables is \( r \)-distributed (Definition 4) will allow us to find, w.h.p. over the choice of \( \Phi \), a good amount of marked variables in any set of clauses, even if the set includes bad clauses, see Lemma 26 for a precise statement. This result is an essential ingredient in our proofs. Secondly, as long as the control variables are left unassigned, the marginals of the marked and auxiliary variables will be near 1/2 as a consequence of the LLL, as we show later in this section (Lemma 21). We remark that, in the definition of \( r \)-distributed set of variables, we ask for \( |\var(c) \cap V| \geq r(k - 3) \) instead of \( |\var(c) \cap V| \geq rk \) to account for the fact that w.h.p. a good clause has at most a repeated variable (Lemma 16) and at most two bad variables (Proposition 3), which will come up in the proofs presented in this section. First, we need the following definition.

Definition 18 (\( \Phi_{\text{good}}, \Phi_{\text{bad}} \)). Let \( \Phi = (\mathcal{V}, \mathcal{C}) \) be a \( k \)-CNF formula. Let \( \Phi_{\text{good}} = (\mathcal{V}_{\text{good}}, \mathcal{C}_{\text{good}}) \) be the CNF formula obtained by taking the good clauses of \( \Phi \) and ignoring the bad variables appearing in them. Let \( \Phi_{\text{bad}} \) be the \( k \)-CNF formula with variables \( \mathcal{V}_{\text{bad}} \) and clauses \( \mathcal{C}_{\text{bad}} \).

Note that in \( G_{\Phi_{\text{good}}} \) two clauses \( c_1 \) and \( c_2 \) in \( \mathcal{C}_{\text{good}} \) are adjacent if and only if \( \var(c_1) \cap \var(c_2) \cap \mathcal{V}_{\text{good}} \neq \emptyset \). By definition of good variables, the maximum degree in \( G_{\Phi_{\text{good}}} \) is at most \( k(\Delta - 1) \), which will be important when applying the LLL. We also need the following version of Chernoff’s bounds.

Lemma 19 (Chernoff’s bounds - [35, Theorem 2.1 and Corollary 4.1]). Let \( n \in \mathbb{N} \), \( p \in [0,1] \), and let \( X_1, \ldots, X_n \) be \( n \) independent random variables with \( X_j \in \{0,1\} \) and \( \Pr(X_j = 1) = p \) for all \( j = 1, \ldots, n \). Let \( X = \sum_{j=1}^{n} X_j \). Then, for any \( r \in (p,1) \) and any \( s \in (0,p) \), we have \( \Pr(X \geq rn) \leq e^{-D(r,p)n} \) and \( \Pr(X \leq sn) \leq e^{-D(s,p)n} \), where, for reals \( x,y \in (0,1) \), \( D(x,y) := x \log (x/y) + (1-x) \log ((1-x)/(1-y)) \) is the Kullback-Leibler divergence.

We can now state the main result of this section. The Lovász local lemma ideas in the proof of Lemma 20 are standard in the literature since the work of Moitra [32] but the quantities involved are adapted to our setting.

Lemma 20. There is a positive integer \( k_0 \) such that for any \( k \geq k_0 \) and any density \( \alpha \) with \( \alpha \leq \alpha_0 \) the following holds w.h.p. over the choice of the random \( k \)-CNF formula \( \Phi = \Phi(k,n,\lfloor \alpha n \rfloor) \):

1. there exists a partial assignment of bad variables that satisfies all bad clauses;
2. there exists an \( r_0 \)-marking of \( \Phi \). Furthermore, for any \( p \in (0,1) \), such an \( r_0 \)-marking can be computed with probability at least \( 1 - p \) in time \( O(n \log(1/p)) \).
Proof of Lemma 20. We note that for any \( k \geq 4 \) our density \( \alpha \leq \alpha_0 = 2^{(r_0 - 2\delta)k} k^3 \) is below the threshold \( c_k = 1.3836 \cdot 2^k / k \) established in [20, Theorem 1.3]. For densities below this threshold, w.h.p. over the choice of \( \Phi \), there is a satisfying assignment for \( \Phi \). When \( \Phi \) is satisfiable, we claim that there is an assignment of the bad variables that satisfies all bad clauses. Indeed, all the variables in bad clauses are bad (Proposition 3) and, thus, the restriction of a satisfying assignment to \( \mathcal{V}_{bad} \) must satisfy all the bad clauses. In the rest of this proof we show that assertion 2 also holds.

In view of Lemma 16, we may assume that \( |\text{var}(c)| \geq k - 1 \) for all \( c \in C \). Let us find the \( r_0 \)-marking \((\mathcal{V}_m, \mathcal{V}_a, \mathcal{V}_c)\). If all clauses are bad, then we set \( \mathcal{V}_c = \mathcal{V}, \mathcal{V}_a = \emptyset \) and \( \mathcal{V}_m = \emptyset \). This is trivially an \( r_0 \)-marking for \( \Phi \). In the rest of the proof we assume that there are good variables. We study the following probability space. For each good variable \( v \), we set \( v \) as “marked” with probability \( \beta \in (0, 1/2) \), “auxiliary” with probability \( \beta \) and “control” with probability \( 1 - 2\beta \). This decision is made independently for each good variable. Each bad variable is set as “control”. Let \( \mathcal{P} \) be the set \( \{ P_v : v \in \mathcal{V}_{good} \} \), where \( P_v \) is the random choice made in this experiment for \( v \). Let \( \mathcal{V}_m \) be the set of marked variables, let \( \mathcal{V}_a \) be the set of auxiliary variables, and let \( \mathcal{V}_c \) be the set of control variables obtained by running this experiment. For each clause \( c \in C_{good} \), let \( A_c \) be the event that \( c \) has less than \( r_0 (k - 3) \) marked variables or less than \( r_0 (k - 3) \) auxiliary variables or less than \( 2r_0 (k - 3) \) good control variables. We are going to apply the LLL on the formula \( \Phi_{good} \) so as to show that \( \Pr(\bigcap_{c \in C_{good}} \overline{A_c}) > 0 \). For each \( c \in C_{good} \), in view of Proposition 3 and the fact that \( |\text{var}(c)| \geq k - 1 \), we have \( |\text{var}(c) \cap \mathcal{V}_{good}| \geq k - 3 \). Hence, we can apply the Chernoff bound given in Lemma 19 with \( n = |\text{var}(c) \cap \mathcal{V}_{good}|, p = \beta \) and \( s = r_0 \) to obtain, for any choice \( V \in \{ \mathcal{V}_m, \mathcal{V}_a \} \),

\[
\Pr_P \left( |\text{var}(c) \cap V| < r_0 (k - 3) \right) \leq e^{-D(r_0, \beta)(k-3)},
\]

When \( V = \mathcal{V}_c \setminus \mathcal{V}_{bad}, n = |\text{var}(c) \cap \mathcal{V}_{good}|, p = 1 - 2\beta \) and \( s = 2r_0 \) we obtain

\[
\Pr_P \left( |\text{var}(c) \cap V| < 2r_0 (k - 3) \right) \leq e^{-D(2r_0, 1-2\beta)(k-3)}.
\]

We have chosen \( r_0 \) to be as large as possible under the restrictions that \( D(r_0, \beta) \geq r_0 \log 2 \) and \( D(2r_0, 1-2\beta) \geq r_0 \log 2 \). The values \( \beta = 0.571027 \) and \( r_0 = 0.117841 \) satisfy these restrictions. We conclude that

\[
\Pr_P (A_c) \leq 2 \cdot e^{-D(r_0, \beta)(k-3)} + e^{-D(2r_0, 1-2\beta)(k-3)} \leq 3 \cdot 2^{-r_0(k-3)}.
\]

Let \( \Delta_0 = 2^{r_0(k-3)}/(3e^2k) \) and let \( x(A_c) = 1/(k\Delta_0) \) for all \( c \in C_{good} \). We check that \( x \) satisfies the condition of the LLL for \( \mathcal{P} \) and \( A = \{ A_c : c \in C_{good} \} \). For \( k \geq 98 \), we find that \( \Delta_0 > 1 \) so \( x(A_c) \in (0, 1) \) for all \( c \in C_{good} \). We note that \( \Gamma(A_c) = \{ A_c' : c' \in C_{good}, c' \neq c, \text{var}(c') \cap \text{var}(c) \cap \mathcal{V}_{good} \neq \emptyset \} \). The graph \( G_{\Phi_{good}} \) given in Definition 12, has maximum degree at most \( k(\Delta - 1) \), so \( |\Gamma(A_c)| \leq k(\Delta - 1) \leq k\Delta_0 \), where the latter inequality holds for large enough \( k \) as \( \Delta = \lceil 2^{(r_0-2\delta)k} \rceil \) (recall that \( \delta = 0.00001 \)). Therefore, we have

\[
x(A_c) \prod_{N \in \Gamma(A_c)} (1 - x(N)) \geq \frac{1}{k\Delta_0} \left( 1 - \frac{1}{k\Delta_0} \right)^{k\Delta_0} \geq \frac{1}{e^2k\Delta_0} = 3 \cdot 2^{-r_0(k-3)},
\]

where we used \( (1 - 1/z^2) \geq e^{-2} \) for all \( z \geq 2 \) in the second inequality. Thus,

\[
x(A_c) \prod_{N \in \Gamma(A_c)} (1 - x(N)) \geq 3 \cdot 2^{-r_0(k-3)} \geq \Pr_P (A_c).
\]

We conclude that, by the LLL, \( \Pr_P \left( \bigcap_{c \in C_{good}} \overline{A_c} \right) > 0 \), so there exists a partition \((\mathcal{V}_m, \mathcal{V}_a, \mathcal{V}_c)\) of the variables of \( \Phi \) such that \( \mathcal{V}_{bad} \subseteq \mathcal{V}_c \) and each good clause contains at least \( r_0 (k - 3) \) marked variables, \( r_0 (k - 3) \) auxiliary variables and \( 2r_0 (k - 3) \) good control variables. That is, \((\mathcal{V}_m, \mathcal{V}_a, \mathcal{V}_c)\) satisfies items 1 and 2 of Definition 4 for \( r = r_0 \). Moreover, with probability at least \( 1 - \delta \), this partition can be computed in \( 4n\alpha\Delta_0 k \log(1/\delta) \) steps with the algorithm of Moser and Tardos [34]. \( \square \)
In the remaining of this section we bound the marginals of \( \mu_\Omega \) (the uniform distribution over the satisfying assignments of the formula \( \Phi \), Definition 5) on any marked and auxiliary variable. In fact, we prove the stronger result that the marginal distribution of \( \mu_\Omega \) on \( V_m \cup V_a \) is very close to the uniform distribution. Recall also that all the variables in bad clauses of \( \Phi \) are bad (Proposition 3), and thus, we can consider the subformula \( \Phi_{\text{bad}} := (V_{\text{bad}}, C_{\text{bad}}) \), which is satisfiable under the hypothesis of Lemma 20.

**Lemma 21.** Let \( \Phi = (V, C) \) be a \( k\)-CNF formula that has an \( r_0\)-marking \( (V_m, V_a, V_c) \). Then either the formula \( \Phi_{\text{bad}} \) is unsatisfiable or the distribution \( \mu_\Omega |_{V_m \cup V_a} \) is \( (2^{-r_0}) k / k \)-uniform.

**Proof.** Let us assume that \( \Phi_{\text{bad}} \) is satisfiable and let us prove that the distribution \( \mu_\Omega |_{V_m \cup V_a} \) (Definition 7) is \( (2^{-r_0}) k / k \)-uniform. Let \( \Lambda_{\text{bad}} \) be an assignment of bad variables that satisfies all bad clauses. Let \( v \in V_m \cup V_a \) and let \( \Lambda \) be an assignment of \( V_m \cup V_a \setminus \{ v \} \) to \( \{ F, T \} \). Let \( \Lambda \cup \Lambda_{\text{bad}} \) be the combined assignment of \( \Lambda \) and \( \Lambda_{\text{bad}} \). We note that \( \Pr_{\mu_\Omega} (\cdot | \tau) \) for any assignment \( \tau \) of some variables. In light of this observation, we are going to prove that

\[
\max \left\{ \Pr_{\mu_\Omega |_{\Lambda \cup \Lambda_{\text{bad}}}} (v \mapsto F), \Pr_{\mu_\Omega |_{\Lambda \cup \Lambda_{\text{bad}}}} (v \mapsto T) \right\} \leq \frac{1}{2} \exp \left( \frac{1}{k} 2^{-r_0} \right), \tag{7}
\]

The result will then follow by the arbitrary choice of \( \Lambda_{\text{bad}} \) and the law of total probability. We apply the LLL to the formula \( \Phi' := \Phi |_{\Lambda \cup \Lambda_{\text{bad}}} \) as follows. Let \( V' \) and \( C' \) be the sets of variables and clauses of \( \Phi' \). Note that, \( V' \subseteq V_{\text{good}}, C' \subseteq C_{\text{good}} \) and \( G_{\Phi'} \) is a subgraph of \( G_{\Phi_{\text{good}}} \) as all bad variables have been assigned a value and all bad clauses have been satisfied. We set \( \Pr_{\mu_\Omega} (v \mapsto \sigma(v)) \) for all \( v \in V', \sigma : V' \rightarrow \{ F, T \} \) is chosen uniformly at random from the set of assignments \( V' \rightarrow \{ F, T \} \), and \( \mathcal{P} = \{ P_v : v \in V' \} \). We define the set \( \Lambda \) as the set containing for all \( c \in C' \) the event \( A_c = \{ \text{the clause } c \text{ is not satisfied by the random assignment } \sigma \} \). By the definition of \( (V_m, V_a, V_c) \), there are at least \( 2r_0 (k - 3) \) good control variables in \( c \). Since good control variables are not assigned a value by \( \Lambda \cup \Lambda_{\text{bad}} \) and, thus, they are in \( V' \), we have \( \Pr_{\mu_\Omega} (A_c) \leq \frac{1}{k^{r_0 (k - 3)}} \). Recall that \( \Delta = \lfloor 2^{(r_0 - 2\delta) k} \rfloor \) (Definition 2). Let \( \Delta_0 = 2^{r_0 (k - 3)} / (e^2 k) \) and let \( x(A_c) = \frac{1}{\Delta_0} \Delta_0 \) for all \( c \in C' \). Let us show that \( x \) satisfies the LLL condition in this setting. In view of \( \Gamma(A_c) = \{ A_{c'} : c' \in C', c' \neq c, \text{var}(c) \cap \text{var}(c') \cap V' \neq \emptyset \} \), which can be identified with a subset of the neighbours of \( c \) in \( G_{\Phi_{\text{good}}} \), and \( | \Gamma(A_c) | \leq k \Delta \leq k \Delta_0 \) for large enough \( k \), we find that

\[
x(A_c) = \prod_{N \in \Gamma(A_c)} (1 - x(N)) \geq \frac{1}{k \Delta_0} \left( 1 - \frac{1}{k} \right)^{\Delta_0} \geq \frac{1}{k \Delta_0} = 2^{-r_0 (k - 3)} \geq \Pr_{\mu_\Omega} (A_c),
\]

where we used \((1 - 1/z)^z \geq e^{-2} \) for all \( z \geq 2 \). Let \( A = \{ v \mapsto T \} := \{ \sigma : V' \rightarrow \{ F, T \} \text{ with } \sigma(v) = T \} \). In \( \Phi' \), we have \( \Gamma(A) = \{ A_c : c \in C', v \in \text{var}(c) \} \), so \( | \Gamma(A) | < \Delta \). By the LLL, we obtain

\[
\Pr_{\mu_\Omega} (v \mapsto T \cap \{ c \in C' : c \neq c', v \in \text{var}(c) \}) \leq \frac{1}{2} \prod_{N \in \Gamma(A)} (1 - x(N))^{-1} \leq \frac{1}{2} \left( 1 - \frac{1}{k \Delta_0} \right)^{-(\Delta - 1)}. \tag{8}
\]

For \( x > 1 \), we have \((1 - 1/x)^{-1} = 1 + 1/(x - 1) \leq \exp(1/(x - 1)) \). We find that

\[
\Pr_{\mu_\Omega} (v \mapsto T \cap \{ c \in C' : c \neq c', v \in \text{var}(c) \}) \leq \frac{1}{2} \exp \left( \frac{\Delta - 1}{k \Delta_0 - 1} \right) \leq \frac{1}{2} \exp \left( \frac{1}{k \Delta_0} \right),
\]

where in the latter inequality we used \((p - j)/(q - j) \leq p/q \) for all \( 0 < j < p \leq q \) and the fact that \( \Delta = \lfloor 2^{(r_0 - 2\delta) k} \rfloor \leq 2^{(r_0 - \delta) k} \cdot 2^{r_0 (k - 3)} / (3e^3 k) = 2^{-(r_0 + \delta) k} \Delta_0 \) for large enough \( k \). We note that \( \Pr_{\mu_\Omega |_{\Lambda \cup \Lambda_{\text{bad}}}} (\cdot) = \Pr_{\mu_\Omega} (\cdot | \{ c \in C' : c \neq c', v \in \text{var}(c) \}) \), which completes the proof of one of the upper bounds of (7). The other upper bound is proved analogously by applying the LLL with \( A = \{ v \mapsto F \} \). \qed
The \(2^{-(r_0+\delta)k/k}\)-uniform property proved in Lemma 21 is remarkably strong: as long as the control variables are left unassigned, the rest of the variables have marginals close to 1/2, even if some of the marked and auxiliary variables are pinned / have already been assigned a value. This property is used several times in this work and will allow us to prove that, for any pinning of some marked variables, the influences between marked variables are bounded. In the following corollary we extend Lemma 21 to the distributions computed by the Glauber dynamics on the marked variables.

**Corollary 22.** Let \(\Phi = (V, C)\) be a \(k\)-CNF formula such that \(\Phi_{\text{bad}}\) is satisfiable and \(\Phi\) has an \(r_0\)-marking \((V_m, V_a, V_c)\). Let \(\rho\) be an integer with \(1 \leq \rho < |V_m|\). Let \(t\) be a non-negative integer and let \(X_t\) be the (random) assignment obtained after running the \(\rho\)-uniform-block Glauber dynamics on the marked variables for \(t\) steps, starting on an assignment \(X_0\) that is chosen uniformly at random. Then the probability distribution of \(X_t\) is \(2^{-(r_0+\delta)k/k}\)-uniform.

**Proof.** Let \(\varepsilon = (2^{-(r_0+\delta)k/k})\). Let \(V_1, V_2, \ldots\), be a possible choice of sets of marked variables to be updated when running the \(\rho\)-uniform-block Glauber dynamics. We are going to prove that, conditioning on this choice of sets of variables, the probability distribution of \(X_t\) is \(\varepsilon\)-uniform. Note that by the law of total probability and the fact that the choice of \(V_1, V_2, \ldots\) is arbitrary, this is enough to conclude the result. We carry out the proof by induction on \(t\). Let \(\pi_t\) be the probability distribution of \(X_t\). As \(\pi_0\) is the uniform distribution over assignments on \(V_m\), the claim holds for \(t = 0\). Let us now assume that \(\pi_{t-1}\) is \(\varepsilon\)-uniform and let us prove that this is also the case for \(\pi_t\). To show the desired uniformity of \(\pi_t\) (cf. Definition 8), consider arbitrary \(v \in V_m\) and \(\Lambda : V_m \setminus \{v\} \rightarrow \{F, T\}\), we need to bound \(\Pr_{\pi_t}(v \mapsto F|\Lambda)\) and \(\Pr_{\pi_t}(v \mapsto T|\Lambda)\). We distinguish two cases:

- **Case** \(v \in V_t\). By definition of the Glauber dynamics, the values of \(X_t\) on \(V_t\) are obtained by sampling from the distribution \(\mu_0\) conditioned on the restriction of \(X_{t-1}\) to \(V_m \setminus V_t\). Thus, we have \(\Pr_{\pi_t}(v \mapsto F|\Lambda) = \Pr_{\mu_{t\Lambda}}(v \mapsto F)\) since the conditioning involving \(\Lambda\) sets all the marked variables other than \(v\). As \(\mu_0|_{V_m \cup V_a}\) is \(\varepsilon\)-uniform by Lemma 21, we conclude that \(\Pr_{\pi_t}(v \mapsto F|\Lambda) = \Pr_{\mu_{t\Lambda}}(v \mapsto F)\leq \frac{1}{2}\exp(\varepsilon)\). The same bound holds for \(v \mapsto T\).

- **Case** \(v \not\in V_t\). If \(v\) is not updated in steps 1 through \(t\), then \(\Pr_{\pi_t}(v \mapsto F|\Lambda) = \Pr_{\pi_0}(v \mapsto F) = 1/2\). Otherwise, let \(j\) be the largest integer with \(j < t\) such that \(v \in V_j\). Let \(\Lambda_j\) be the restriction of \(\Lambda\) to \(V_m \setminus \bigcup_{i \in (j+1, j+2, \ldots, t)} V_i\). By the induction hypothesis, \(\Pr_{\pi_t}(v \mapsto F|\Lambda_j) = \Pr_{\pi_j}(v \mapsto F|\Lambda_j)\leq (1/2)\exp(\varepsilon)\). The same bound holds for \(v \mapsto T\).

As both cases are exhaustive, the proof is concluded.

Previous work on counting/sampling satisfying assignments of \(k\)-CNF formulas does not require the use of auxiliary variables, so the marking used is of the form \((V_m, V_c)\). Here auxiliary variables play an essential role in bounding the influences between marked variables as we illustrated in Section 2. In order for this approach to be successful, we have to show that a large proportion of the variables are marked. We conclude this section with the following bound on the size of \(V_m\).

**Corollary 23.** There is an integer \(k_0\) such that for any \(k \geq k_0\) and any density \(\alpha\) with \(\alpha \leq \alpha_0\) the following holds w.h.p. over the choice of the random \(k\)-CNF formula \(\Phi = \Phi(k, n, [\alpha n])\). For any set of good variables \(V\) that is \(r_0\)-distributed we have \(|V| \geq (r_0 - \delta)(\alpha k / \Delta)n\).

**Proof.** W.h.p. over the choice of \(\Phi\), Lemma 15 holds. We combine this with the inequality \(\alpha_0 \leq \Delta/k^3\) and the fact that a good variable occurs in at most \(\Delta\) good clauses to find that

\[
|V| \geq \frac{r_0(k-3)|C_{\text{good}}|}{\Delta} \geq \frac{r_0(k-3)}{\Delta} \left(1 - \frac{1}{k}\right)|C| \geq \frac{r_0(k-4)}{\Delta}(\alpha n - 1),
\]

which is at least \((r_0 - \delta)(\alpha k / \Delta)n\) for large enough \(k\).
6 Analysis of the connected components of $\Phi^A$

In this section we prove Lemma 13, which bounds the size of the connected components of $\Phi^A$, where $\Lambda$ is drawn from a $(1/k)$-uniform distribution over a $r_0$-distributed set of good variables. In order to carry out this proof, we have to understand the structure of logarithmic-sized sets of clauses of the random $k$-CNF formula $\Phi$. Section 6.1 is devoted to this purpose. In Section 6.2 we apply the results of Section 6.1 to obtain a lower bound of the number of marked/auxiliary variables in logarithmic-sized sets of clauses. Finally, in Section 6.3 we complete the proof of Lemma 13.

6.1 Logarithmic-sized sets of clauses in the random $k$-SAT model

A connected graph $H = (V, E)$ has tree-excess $c \in \mathbb{Z}_{\geq 0}$ if $|E| = c + |V| - 1$. It turns out that, w.h.p. over the choice of $\Phi$, small connected sets of clauses of $\Phi$ have tree-excess that only depends on $k$ and the density $\alpha$. This property is established in Lemma 24 and is essential to our proofs.

Lemma 24. Let $k \geq 3$ be an integer. Let $b > 0$ and $\alpha > 0$ be real numbers. W.h.p. over the choice of the random $k$-CNF formula $\Phi = \Phi(k, n, [\alpha n])$, every connected subset of clauses with size at most $b \log(n)$ has tree-excess at most $c := \max \{1, 2b \log(ek^2\alpha)\}$.

Proof. Let $n$ be the number of variables and $m$ be the number of clauses of $\Phi$, so $m/n \leq \alpha$. Note that the probability that two clauses of $\Phi$ are not disjoint is at most $k^2/n$. Let $\ell \in \{1, 2, \ldots, \lfloor b \log(n) \rfloor \}$. We upper bound the probability that there is a connected subset of clauses of size $\ell$ with tree-excess at least $c + 1$ by

\[
\binom{m}{\ell} \ell^{-2} \left( \frac{\ell(\ell - 1)/2}{c + 1} \right) \left( \frac{k^2}{n} \right)^{\ell+c},
\]

where the factors appearing are the following ones:

- $\binom{m}{\ell}$ is the number of subsets of clauses of size $\ell$;
- $\ell^{-2}$ is the number of trees on $\ell$ labelled vertices;
- $\left( \frac{\ell(\ell - 1)/2}{c + 1} \right)$ is the number of ways to pick $c + 1$ pairs of distinct clauses of a set of size $\ell$;
- $\left( \frac{k^2}{n} \right)^{\ell+c}$ is an upper bound of the probability that all the edges chosen in the two previous items appear in the graph $G_\Phi$.

We are going to show that the probability given in (8) is $O(n^{-c/4})$, where the hidden constant only depends on $k$. If this holds, by a union bound over $\ell \in \{1, 2, \ldots, \lfloor b \log(n) \rfloor \}$, we would find that the probability that there is a connected subset of clauses of $\Phi$ with size at most $b \log(n)$ and tree-excess at least $c + 1$ is $O(b \log(n)n^{-c/4}) = o(1)$. This would complete the proof. Using the inequality $\binom{n}{q} \leq (ep/q)^q$ and $m/n \leq \alpha$ we can bound (8) by

\[
\left( \frac{em}{\ell} \right) \ell^{-2} \left( \frac{\ell(\ell - 1)/2}{c + 1} \right)^{c+1} \left( \frac{k^2}{n} \right)^{\ell+c} \leq \left( \frac{em}{\ell} \right) \ell^{-2} \left( \frac{\ell^2/2}{c + 1} \right)^{c+1} \left( \frac{k^2}{n} \right)^{\ell+c} \leq \left( \frac{e}{2c+2} \right)^{c+1} \left( \frac{emk^2}{n} \right) \ell \left( \frac{k^2}{n} \right)^{c}.
\]

Now we distinguish two cases:
• Case when \( e^k \alpha \leq 1 \). We have \( c = 1 \) by definition. Thus, (9) can be further bounded by
\[
\left( \frac{e}{2c+2} \right)^{c+1} \left( \frac{k^2 \ell^2}{n} \right)^c = O \left( \frac{(\log n)^2}{n} \right) = O \left( n^{-c/4} \right)
\]
as we wanted.

• Case when \( e^k \alpha > 1 \). Then, as \( \ell \leq b \log n \) and \( b \log(e^k \alpha) \leq c/2 \) by definition, we have
\[
\left( e^k \alpha \right)^\ell \leq \left( e^k \alpha \right)^{b \log n} = n^{b \log(e^k \alpha)} \leq n^{c/2}.
\]
We conclude that (9) can be further bounded by
\[
\left( \frac{e}{2c+2} \right)^{c+1} \left( \frac{k^2 \ell^2}{\sqrt{n}} \right)^c = \left( \frac{e}{2c+2} \right)^{c+1} \left( \frac{k^4 \ell^4}{n} \right)^{c/2} = O \left( n^{-c/4} \right)
\]
as we wanted, where we used \( c > 0 \).

Recall that in Lemma 15 we established that, in sets of clauses that have at least \( 2k^4 \log n \) variables, the number of bad clauses of \( \Phi \) is not too large. We aim to apply Lemma 15 to logarithmic-sized sets of clauses. In general, \(|Y|\) might be significantly larger than \(|\text{var}(Y)|\), so it is not clear how to apply Lemma 15. However, in the random \( k\)-CNF formula setting the following holds.

**Lemma 25.** Let \( k \geq 3 \) be an integer and let \( a > 0 \) and \( \alpha > 0 \) be real numbers. W.h.p. over the choice of \( \Phi = \Phi(k, n, \lfloor \alpha n \rfloor) \), for every set of clauses \( Y \) with \(|Y| \geq a \log n \), we have \(|\text{var}(Y)| \geq a \log n \).

**Proof.** Let \( \ell := \lfloor a \log n \rfloor - 1 \) and let \( m = \lfloor \alpha n \rfloor \). We prove the equivalent statement that, w.h.p. over the choice of \( \Phi \), for every set of clauses \( Y \) with \(|\text{var}(Y)| \leq \ell \), we have \(|Y| \leq \ell \). We note that if there is a set of clauses \( Y \) with \(|\text{var}(Y)| \leq \ell \) and \(|Y| > \ell \), then for any subset \( Y' \) of \( Y \) with \(|Y'| = \ell + 1 \) we have \(|\text{var}(Y')| \leq |\text{var}(Y)| \leq \ell \). Hence, it suffices to prove that there is no set \( Y \) of clauses with \(|\text{var}(Y)| \leq \ell \) and \(|Y| = \ell + 1 \). We can assume \( n \) is large enough so that \( \ell \leq e \cdot n \).

Let \( \mathcal{E} \) be the event that there is a set of clauses \( Y \) of size \( \ell + 1 \) and a set of variables \( X \) of size \( \ell \) such that all clauses in \( Y \) have all variables in \( X \). Then by a union bound
\[
\Pr(\mathcal{E}) \leq \left( \frac{m}{\ell + 1} \right) \left( \frac{n}{\ell} \right) \left( \frac{\ell}{n} \right)^{(\ell+1)k},
\]
where the first factor is the number of sets \( Y \), the second factor is the number of sets \( X \) and the third factor is the probability that all variables in the clauses of \( Y \) are in \( X \). From the well-known bound \( \binom{p}{q} \leq (ep/q)^q \), we obtain
\[
\Pr(\mathcal{E}) \leq \left( \frac{em}{\ell + 1} \right)^{\ell+1} \left( \frac{em}{\ell} \right)^{\ell} \left( \frac{\ell}{n} \right)^{(\ell+1)k} \leq \left( \frac{em}{\ell} \right)^{\ell+1} \left( \frac{en}{\ell} \right)^{\ell+1} \left( \frac{\ell}{n} \right)^{(\ell+1)k} \leq \left( \frac{em}{\ell} \right)^{\ell+1} \left( \frac{en}{\ell} \right)^{\ell+1} \left( \frac{\ell}{n} \right)^{(\ell+1)k} = \left( e^2 \frac{k^2}{n^{k-2}} \right)^{\ell+1},
\]
which is \( O(\log(n)/n) \) because \( k \geq 3 \) and \( \ell = O(\log n) \). \( \square \)
6.2 Number of marked variables in logarithmic-sized sets of clauses

Our results on random $k$-CNF formulas can now be combined to give a lower bound on the number of marked / auxiliary variables in logarithmic-sized sets of clauses. We prove this result in a more general setting by considering a set of good variables $V$ that is $r_0$-distributed for the formula $\Phi$. The reader can think of $V$ as the set of marked variables or the set of auxiliary variables. Recall that $\alpha_0 = 2(\alpha_0 - 2\rho)k/k^3$ (Definition 2).

**Lemma 26.** Let $\delta \in (0, r_0)$. There is a positive integer $k_0$ such that, for any integer $k \geq k_0$, any density $\alpha \leq \alpha_0$ and any real number $b$ with $2k^4 < b$, the following holds w.h.p. over the choice of $\Phi = \Phi(k, n, \lfloor \alpha n \rfloor)$. Let $V$ be a set of good variables that is $r_0$-distributed. Then, for every set of clauses $Y$ that is connected in $G_\Phi$ such that $2k^4 \log(n) \leq |Y| \leq b \log(n)$, we have $|\var(Y) \cap V| \geq (r_0 - \delta)k|Y|$.

**Proof.** Let $a = 2k^4$. We apply Lemma 15 to find that there is $k_1$ such that for $k \geq k_1$, w.h.p. over the choice of $\Phi$, for every set of clauses $Y$ that is connected in $G_\Phi$, we have

\[ \text{if } |\var(Y)| \geq a \log(n), \text{ then } |Y \cap C_{\text{bad}}| \leq |Y|/k. \tag{10} \]

We apply Lemma 25 with $a = 2k^4$ to find that, w.h.p. over the choice of $\Phi$, for every set of clauses $Y$, we have

\[ \text{if } |Y| \geq a \log(n), \text{ then } |\var(Y)| \geq a \log(n). \tag{11} \]

Finally, for any $b > 0$, we apply Lemma 24, obtaining that, w.h.p. over the choice of $\Phi$, for every set of clauses $Y$ that is connected in $G_\Phi$, we have

\[ \text{if } |Y| \leq b \log n, \text{ then } Y \text{ has tree-excess at most } c = \max\{1, 2b \log(ek^2\alpha)\} = O(1). \tag{12} \]

Let $Y$ be a set of clauses that is connected in $G_\Phi$ such that $a \log(n) \leq |Y| \leq b \log(n)$. Then, by (11) and (10), we have $|Y \cap C_{\text{good}}| \geq |Y|(1 - 1/k)$. By definition of $r_0$-distributed (Definition 4), each good clause has at least $r_0(k-3)$ variables in $V$. As there are at most $|Y| - 1 + c$ edges in $G_\Phi$ joining clauses in $Y$, see (12), and two distinct clauses only share at most two variables by Lemma 16, we have

\[ |\var(Y) \cap V| \geq r_0(k-3) \left(1 - \frac{1}{k}\right) |Y| - 2(|Y| + c - 1) \]
\[ \geq (r_0(k-4) - 2)|Y| - 2(c-1). \]

There is $k_0 \geq k_1$ such that for $k \geq k_0$, we find that, for any set of clauses $Y$ that is connected in $G_\Phi$ and has $a \log(n) \leq |Y| \leq b \log(n)$, $|\var(Y) \cap V| \geq (r_0 - \delta/2)k|Y| - 2(c-1)$. Therefore, using $2(c-1) = O(1)$, for large enough $n$ we conclude that $|\var(Y) \cap V| \geq (r_0 - \delta)k|Y|$ and the result follows. \hfill $\square$

6.3 Proof of Lemma 13

We use the following result of [21] on the number of connected sets of clauses in $G_\Phi$.

**Lemma 27** ([21, Lemma 8.6]). W.h.p. over the choice of $\Phi$, for any clause $c$, the number of connected sets of clauses in $G_\Phi$ with size $\ell \geq \log n$ containing $c$ is at most $(9k^2\alpha)^\ell$.

We can now complete the proof of Lemma 13.

**Lemma 13.** There is an integer $k_0 \geq 3$ such that, for any integer $k \geq k_0$, any density $\alpha \leq 2\rho k$, and any real number $b$ with $a := 2k^4 < b$, the following holds w.h.p. over the choice of $\Phi = \Phi(k, n, [\alpha n])$.

Let $L$ be an integer satisfying $a \log n \leq L \leq b \log n$. Let $V$ be a set of good variables of $\Phi$ that is $r_0$-distributed, let $\mu$ be a $(1/k)$-uniform distribution over the assignments $V \to \{F, T\}$, and let $\rho$ be an integer
Consider the following experiment. First, draw $S \subseteq V$ from the uniform distribution $\tau$ over subsets of $V$ with size $\rho$. Then, sample an assignment $\Lambda$ from $\mu_{|V\setminus S}$. Denote by $\mathcal{F}$ the event that there is a connected set of clauses $Y$ of $\Phi$ with $|Y| \geq L$ such that all clauses in $Y$ are unsatisfied by $\Lambda$. Then $\Pr_{S \sim \tau} \left( \Pr_{\Lambda \sim \mu_{|V\setminus S}} (\mathcal{F}) \leq 2^{-\delta k L} \right) \geq 1 - 2^{-\delta k L}$.

**Proof.** Since $\delta = 0.00001$, $a = 2k^4$, $r = 0.1178$, and $r_0 = 0.117841$, we can pick $k_0$ large enough so that for all $k \geq k_0$ we have

$$2^{\alpha k} \leq \frac{2^{(r_0 - 3\delta)k}}{18ek^3} \leq \alpha_0 = \frac{2^{(r_0 - 2\delta)k}}{k^3}.$$  

(13)

We apply Lemma 26 with our choices of $b$ and with $\hat{\delta} = \delta$ to conclude that, w.h.p. over the choice of $\Phi$, for every connected set of clauses $Z \subseteq C$ we have

$$\text{if } a \log(n) \leq |Z| \leq b \log(n), \text{ then } |\text{var}(Z) \cap V| \geq (r_0 - \delta)k|Z|.$$  

(14)

We also need the following result on random $k$-CNF formulas. For each clause $c \in C$, let

$$Z(c, L) = \{Z \subseteq C : c \in Z, Z \text{ is connected in } G_\Phi, |Z| = L\}.$$  

Then, w.h.p. over the choice of $\Phi$, Lemma 27 shows that, as long as $L \geq \log n$,

$$\text{for any clause } c \in C \text{ we have } |Z(c, L)| \leq (9k^2 \alpha)^L.$$  

(15)

The facts that we have just established using Lemma 26 and Lemma 27 are all the properties of random formulas that we need in this proof.

Let $L$ be an integer with $a \log n \leq L \leq b \log n$. First, we are going to fix $S \subseteq V$ with $|S| = \rho$ and study the event $\mathcal{F}$ described in the statement. For $c \in C$ and $Z \in Z(c, L)$, we denote by $\mathcal{E}_1(Z, S)$ the event that $Z \subseteq C^\Lambda$, where $\Lambda$ is drawn from $\mu_{|V\setminus S}$, see Definition 7. Recall that $Z \subseteq C^\Lambda$ means that none of the clauses in $Z$ are satisfied by the assignment $\Lambda$ (Definition 5). We note that $\mathcal{F} = \bigcup_{c \in C, Z \in Z(c, L)} \mathcal{E}_1(Z, S)$.

We are going to show that, for large enough $n$,

$$\Pr_{S \sim \tau} \left( \Pr_{\Lambda \sim \mu_{|V\setminus S}} \left( \bigcup_{c \in C, Z \in Z(c, L)} \mathcal{E}_1(Z, S) \right) > 2^{-\delta k L} \right) \leq 2^{-\delta k L},$$  

(16)

which is equivalent to the result stated in this lemma. We note that the left-hand side of (16) can be upper bounded by

$$\Pr_{S \sim \tau} \left( \exists c \in C, Z \in Z(c, L) : \Pr_{\Lambda \sim \mu_{|V\setminus S}} (\mathcal{E}_1(Z, S)) > \frac{2^{-\delta k L}}{|C| \cdot |Z(c, L)|} \right) \leq \sum_{c \in C, Z \in Z(c, L)} \Pr_{S \sim \tau} \left( \Pr_{\Lambda \sim \mu_{|V\setminus S}} (\mathcal{E}_1(Z, S)) > \frac{2^{-\delta k L}}{|C| \cdot |Z(c, L)|} \right).$$  

(17)

We are going to show that, for any $c \in C$ and $Z \in Z(c, L)$,

$$\Pr_{S \sim \tau} \left( \Pr_{\Lambda \sim \mu_{|V\setminus S}} (\mathcal{E}_1(Z, S)) > \frac{2^{-\delta k L}}{|C| \cdot |Z(c, L)|} \right) \leq \left( 2ek \cdot 2^{-(r_0 - \delta)k} \right)^L.$$  

(18)

Before proving (18), let us complete the proof assuming that this inequality holds. Recall that $\alpha \leq 2^{\alpha k} \leq 2^{-(r_0 - 3\delta)k}/(18ek^3)$. Hence, in light of (15), we have $|Z(c, L)| \leq (2^{(r_0 - 3\delta)k/(2ek)})^L$. We use the following observation,

$$\text{for } k > 1/(\delta \log 2) \text{ and for large enough } n, \ |C| \leq n \alpha \leq n^\delta 2k^5 \log 2 \leq 2^{\delta k L}. $$  

(19)
Combining (17), (18) and (19), we conclude the left-hand size of (16) is bounded above by

$$\sum_{c \in \mathcal{C}, Z \in \mathcal{Z}(c, L)} \left(2ek \cdot 2^{-(r_0 - \delta)k}\right)^L \leq n\alpha \cdot \left(\frac{2^{(r_0 - 3\delta)k}}{2ek}\right)^L \cdot \left(2ek \cdot 2^{-(r_0 - \delta)k}\right)^L = n\alpha 2^{-2\delta kL} \leq 2^{-\delta kL},$$

which completes the proof of (16), and hence the proof of the lemma, subject to (18).

To prove (18), we are going to find many $S$ for which $\Pr_{\Lambda \sim \mu_{V \setminus S}}(E_1(Z, S)) \leq 2^{-\delta kL/(|\mathcal{C}| \cdot |\mathcal{Z}(c, L)|)}$ holds. With this in mind, we introduce an event that may occur when sampling $S$:

$$E_2(Z) := \text{the random set } S \subseteq V \text{ that we select contains fewer variables in var}(Z) \cap V \text{ with } \ell := |\text{var}(Z) \cap V|/k \text{ variables in var}(Z) \cap V).$$

We will show (in equation (24)) that the event $E_2(Z)$ holds for most choices of $S$. Before proving this claim, let us assume that $E_2(Z)$ holds for $S$ and let us prove that $\Pr_{\Lambda \sim \mu_{V \setminus S}}(E_1(Z, S)) \leq 2^{-\delta kL/(|\mathcal{C}| \cdot |\mathcal{Z}(c, L)|)}$. If there are $c_1, c_2 \in \mathcal{Z}$ and $v \in \text{var}(c_1) \cap \text{var}(c_2) \cap (V \setminus S)$ such that $c_1 \neq c_2$ and the literal of $v$ in $c_1$ is the negation of the literal of $v$ in $c_2$, then at least one of $c_1$ and $c_2$ is satisfied by the assignment $\Lambda: V \setminus S \rightarrow \{\text{F, T}\}$. In this case we have $\Pr_{\Lambda \sim \mu_{V \setminus S}}(E_1(Z, S)) = 0$. Let us now consider the complementary case:

$$\text{for all } c_1, c_2 \in \mathcal{Z} \text{ with } c_1 \neq c_2 \text{ and } v \in \text{var}(c_1) \cap \text{var}(c_2) \cap (V \setminus S),$$

the literal of $v$ in $c_1$ is the same as the literal of $v$ in $c_2$. (21)

In this setting, we call $\omega(v)$ the value of $v$ that does not satisfy the clauses in $Z$ that contain $v$. Note that $\omega(v)$ is well-defined by assumption (21). Let $u_1, u_2, \ldots, u_t$ be the list of variables in $(\text{var}(Z) \cap V) \setminus S$. We denote by $\mathcal{W}_j$ the event that $u_j$ is assigned the value $\omega(u_j)$ by $\Lambda$ when sampling $\Lambda \sim \mu_{V \setminus S}$. Then, by definition of $\mathcal{W}_j$, we have

$$\Pr_{\Lambda \sim \mu_{V \setminus S}}(E_1(Z, S)) = \prod_{j=1}^{t} \Pr_{\Lambda \sim \mu_{V \setminus S}}(\mathcal{W}_j | \bigcap_{i=1}^{j-1} \mathcal{W}_i).$$

As $\mu$ is $(1/k)$-uniform, we find that $\Pr_{\Lambda \sim \mu_{V \setminus S}}(\mathcal{W}_j | \bigcap_{i=1}^{j-1} \mathcal{W}_i) \leq (1/2) \exp(1/k)$ for all $j \in \{1, 2, \ldots, t\}$. We conclude that

$$\Pr_{\Lambda \sim \mu_{V \setminus S}}(E_1(Z, S)) \leq \left(\frac{1}{2} \exp\left(\frac{1}{k}\right)\right)^t.$$

From (14) and the fact that $E_2(Z)$ holds for $S$, we have

$$t = |\text{var}(Z) \cap (V \setminus S)| \geq |\text{var}(Z) \cap V| - |\text{var}(Z) \cap V|/k = |\text{var}(Z) \cap V| (1 - 1/k) - 1 \geq (r_0 - \delta) L (k - 1) - 1.$$

It follows that

$$\Pr_{\Lambda \sim \mu_{V \setminus S}}(E_1(Z, S)) \leq \left(\frac{1}{2} \exp\left(\frac{1}{k}\right)\right)^{(r_0 - \delta)(k - 1)L - 1} \leq 2 \cdot 2^{- (r_0 - \delta) k} \exp\left(\frac{(r_0 - \delta)(k - 1)}{k}\right) \leq \left(4e \cdot 2^{-(r_0 - \delta)k}\right)^{L},$$

which proves (18).
where we used that $1/2 \leq (1/2) \exp(1/k) < 1$ in the second and third inequality. As $\alpha \leq 2^{r_k} \leq 2^{(r_0-3\delta)k}/(18e_k^3) \leq 2^{(r_0-3\delta)k}/(9\cdot 4e_k^2)$ by hypothesis and (13), we find that

$$
\left(4e \cdot 2^{-\left(r_0-\delta\right)k}\right)^L = \left(\frac{9 \cdot 4e_k^2 \cdot \alpha \cdot 2^{-\left(r_0-\delta\right)k}}{9k^2\alpha}\right)^L \leq \left(\frac{2^{-2\delta L}}{9k^2\alpha}\right)^L \leq \frac{2^{-2\delta L}}{|\mathcal{Z}(c, L)|} \leq \frac{2^{-\delta L}}{|\mathcal{C}| \cdot |\mathcal{Z}(c, L)|},
$$

(22)

where in the second to last inequality we applied the bound on the size of $\mathcal{Z}(c, L)$ given in (15), and in the last inequality we used (19). As $S$ was picked as any subset of $V$ with $|S| = \rho$ such that $\mathcal{E}_2(Z)$ holds, it follows that

$$
\mathbb{P}_{S^\sim \tau} \left( \mathbb{P}_{A^\sim \mu \setminus S} (\mathcal{E}_1(Z, S)) > \frac{2^{-\delta L}}{|\mathcal{C}| \cdot |\mathcal{Z}(c, L)|} \right) \leq \mathbb{P}_{S^\sim \tau} (\mathcal{E}_2(Z)).
$$

(23)

In order to prove (18), which finishes the proof, we need to show $\mathbb{P}_{S^\sim \tau} (\mathcal{E}_2(Z)) \leq (2ek \cdot 2^{-\left(r_0-\delta\right)k})^L$. The probability of $\mathcal{E}_2(Z)$ can be bounded as follows. Recall that $|S| = \rho$. If $\rho < \ell$, then, by the definition of $\mathcal{E}_2(Z)$ in (20), we obtain $\mathbb{P}_{S^\sim \tau} (\mathcal{E}_2(Z)) = 1$. Otherwise, the number of choices of $S$ (with $|S| = \rho$) such that $|S \cap \text{var}(Z) \cap V| \geq \ell$ is at most $\binom{|\text{var}(Z)\cap V|}{\ell}$ $\binom{|V| - \ell}{\rho - \ell}$. Hence, we have

$$
\mathbb{P}_{S^\sim \tau} (\mathcal{E}_2(Z)) \leq \left(\frac{|V|}{\rho}\right)^{\ell-1} \left(\frac{|\text{var}(Z)\cap V|}{\rho - \ell}\right) \leq \frac{\rho(\rho - 1) \cdots (\rho - \ell + 1)}{|V|(|V| - 1) \cdots (|V| - \ell + 1)} \left(\frac{|\text{var}(Z)\cap V|}{\ell}\right)^\ell \leq \left(\frac{\rho}{|V|}\right)^\ell \left(\frac{e|\text{var}(Z)\cap V|}{\ell}\right)^\ell \leq \left(\frac{\rho}{|V|}\right)^\ell \left(\frac{\rho}{|V|}\right)^{ek^2}^\ell,
$$

where we used $\ell := \left|\frac{|\text{var}(Z) \cap V|}{|V|}\right| \geq \frac{|\text{var}(Z)\cap V|}{|V|}, (p - i)/(q - i) \leq p/q$ for any $0 < i < p < q$ and $(\ell)^\ell \leq (ep/q)^{\ell^2}$. Combining this with the hypothesis $\rho \leq |V|/2^k$ and the bound $\ell \geq (r_0 - \delta)L$, see (14), we obtain

$$
\mathbb{P}_{S^\sim \tau} (\mathcal{E}_2(Z)) \leq \left(ek2^{-k}\right)^\ell \leq \left(ek\right)^{\rho - \delta} \cdot 2^{-\left(r_0-\delta\right)k}^L \leq \left(2ek \cdot 2^{-\left(r_0-\delta\right)k}\right)^L.
$$

(24)

The bound (18) follows from combining (23) and (24), which completes the proof.

\section{Sampling from small connected components}

In this section we prove Lemma 14. Recall that Lemma 14 claims the existence of a procedure to sample from marginals of the uniform distribution on the satisfying assignments of $\Phi^A$ when the connected components of $G_{\Phi^A}$ have small size. Here we make this procedure explicit. Our algorithm exploits the fact that the tree-excess of logarithmic-sized subsets of $G_{\Phi}$ is bounded by a constant depending only on $k$, see Lemma 24, and the fact that when $G_{\Phi}$ is acyclic, we can exactly count and sample satisfying assignments efficiently (Proposition 28).

**Proposition 28.** There is an algorithm that, for any $k$-CNF formula $\Phi = (V, C)$ such that $G_{\Phi}$ is a tree, computes the number of satisfying assignments of $\Phi$ in time $O(4^k |C|)$.

**Proof.** We give an algorithm based on dynamic programming. Let us fix a vertex $l$ clause $c$ of $G_{\Phi}$ as the root and consider the corresponding directed tree structure $T := (G_{\Phi}, c)$. For any clause $c'$ of $\Phi$, let $T_{c'}$ be the subtree of $T$ hanging from $c'$. For any assignment $\sigma$: $\text{var}(c') \rightarrow \{\text{F}, \text{T}\}$, let $\text{sa}(c', \sigma)$ denote the number
of satisfying assignments of the formula determined by $T_{c'}$ that extend $\sigma$. Our goal is computing the number of satisfying assignments of $\Phi$, which, under this notation, is equal to

$$sa(\Phi) := \sum_{\sigma: \text{var}(c) \to \{F, T\}} sa(c, \sigma).$$

(25)

We do this by computing $sa(c', \sigma)$ for any clause $c'$ and any assignment $\sigma: \text{var}(c') \to \{F, T\}$. Using the tree structure of $T$, we show that $sa(c', \sigma)$ satisfies a recurrence. There are two cases:

1. $c'$ is a leaf. Then $sa(c', \sigma) = 1$ if $c'$ is satisfied by $\sigma$ and 0 otherwise.

2. $c'$ is not a leaf. Let $T_1, \ldots, T_l$ be the trees hanging from $c'$ in $T$ and let $c_1, \ldots, c_l$ be their roots. Then, since $T_1, \ldots, T_l$ do not share variables as $G_\Phi$ is acyclic, we have

$$sa(c', \sigma) = \prod_{j=1}^{l} \sum_{\tau \in A(c_j, \sigma)} sa(c_j, \tau),$$

where $A(c_j, \sigma)$ is the set of assignments of the variables in $\text{var}(c_j)$ that agree with $\sigma$ on $\text{var}(c') \cap \text{var}(c_j)$.

We can apply this recurrence with dynamic programming to compute $sa(c, \sigma)$ for any assignment $\sigma: \text{var}(c) \to \{F, T\}$. More explicitly, we compute $sa(c', \sigma)$ by levels of the tree, starting from the deepest level, where all nodes are leaves, and ending at the root $c$. This involves computing at most $2^k$ entries $sa(c', \cdot)$ per clause $c'$ of $\Phi$. After computing all the entries appearing in this recurrence, we compute the number of satisfying assignments of $\Phi$, $sa(\Phi)$, as in equation (25). The overall procedure takes at most $O(4^k |C|)$ steps since each entry $sa(c', \sigma)$ is accessed at most $2^k$ times when computing the corresponding entries for the parent of $c'$, and there are at most $2^k |C(T)|$ entries.

In Algorithm 3 we give an algorithm based on Proposition 28 to count satisfying assignments of a $k$-CNF formula. Recall the folklore fact that if we can count satisfying assignments then we can sample from the marginal of $\mu_\Omega$ on $v$ by counting the satisfying assignments of $\Phi_{v \not\to F}$ and $\Phi_{v \not\to T}$.

**Algorithm 3 Counting satisfying assignments via trees**

**Input:** a $k$-CNF formula $\Phi = (V, C)$  
**Output:** The number of satisfying assignments of $\Phi$.

1: Find a spanning forest $T$ of $G_\Phi$.
2: Let $V_T$ be the set of variables that gives rise to edges of $G_\Phi$ that are not in $T$.
3: $\text{count} \leftarrow 0$.
4: for all $\Lambda: V_T \to \{F, T\}$ do
5: Note that the graph $G_{\Phi \Lambda}$ is acyclic. Hence, we can count the number of satisfying assignments of $\Phi^\Lambda$ in time $O(4^k |C(\Phi^\Lambda)|)$ by applying Proposition 28 to each connected component of $G_{\Phi \Lambda}$ and taking the product of the numbers obtained. Let $sa(\Phi^\Lambda)$ be the result of this computation.
6: $\text{count} \leftarrow \text{count} + sa(\Phi^\Lambda)$.
7: end for
8: return $\text{count}$

**Proposition 29.** Let $\Phi = (V, C)$ be a $k$-CNF formula and let $c$ be the tree-excess of $G_\Phi$. Then Algorithm 3 counts the number of satisfying assignments of $\Phi$ in time $O(2^{k(c+2)} |C|)$. 
Proof. We note that, in the execution of Algorithm 3, we have $|\mathcal{V}_T| \leq kc$. Hence, there are at most $2^{kc}$ iterations of the for loop and each one takes $O(4^k|C|)$ steps, so the running time follows. The fact that the algorithm is correct follows from the correctness of the procedure presented in Proposition 28.

Even though the running time of Algorithm 3 is not polynomial in the size of the formula $\Phi$ (in fact, it is exponential in general), we obtain linear running time when the formulas considered have constant tree-excess. As shown in Lemma 24, this is the case for logarithmic-sized subsets of clauses of random formulas. We can now finish the proof of Lemma 14.

Lemma 14. There is an integer $k_0 \geq 3$ such that, for any integers $k \geq k_0$, $\xi \geq 1$ and any density $\alpha \leq 2^r k$, the following holds w.h.p. over the choice of $\Phi = \Phi(k, n, [\alpha n])$. Let $V$ be a subset of variables and let $\Lambda : V \rightarrow \{F, T\}$ be a partial assignment such that all the connected components in $G_{\Phi, \Lambda}$ have size at most $2k^4(1 + \xi) \log(n)$. Then, there is an algorithm that, for any $S \subseteq V \setminus V$, samples an assignment from $\mu_{\Omega \Lambda}|_S$ in time $O(|S| \log n)$.

Proof. We apply Lemma 24 with $b = 2k^4(\xi + 1)$, so, w.h.p. over the choice of $\Phi = \Phi(k, n, [\alpha n])$, any connected set of clauses in $G_{\Phi}$ with size at most $b \log(n)$ has tree-excess at most $c = \max\{1, 2b \log(eak^2)\} = O(1)$. First, we give an algorithm for the case $|S| = 1$. Let $\Phi$, $V$ and $\Lambda$ as in the statement, and let $S = \{v\}$. Let $H$ be the connected component of the clauses that contain $v$ in $G_{\Phi, \Lambda}$, and let $\Phi' = (V', C')$ be the subformula of $\Phi^v$ with $G_{\Phi'} = H$. The formula $\Phi'$ has size at most $b \log(n)$. Moreover, the graph $G_{\Phi'} = H$ has tree-excess at most $c$ as $H$ is a subgraph of $G_{\Phi}$ with size at most $b \log(n)$. Thus, we can apply Proposition 29 to count the number of satisfying assignments of $\Phi'^w \rightarrow \mathcal{F}$ and $\Phi'^w \rightarrow \mathcal{T}$ in time $O(2^{k(c+2)}|C'|) = O(\log n)$. Let these numbers be $t_0$ and $t_1$ respectively. It is straightforward to use $t_0$ and $t_1$ to sample from the marginal of the distribution $\mu_{\Omega \Lambda}$ for $v$; we only have to sample an integer $t \in [0, t_0 + t_1]$ and output $\mathcal{F}$ if $t < t_0$ and $\mathcal{T}$ otherwise. The whole process takes time $O(\log n)$.

Finally, we argue how to extend this algorithm to the case $|S| > 1$. For this, first, we give an order to the variables in $S$, say $u_1, u_2, \ldots, u_\ell$. We then call the algorithm described in the paragraph above once for each variable in $u_1, u_2, \ldots, u_\ell$. The inputs of the algorithm in the $j$-th call are the variable $u_j$ and the assignment $\Lambda_j = \Lambda \cup \tau_{j-1}$, where $\tau_{j-1}$ is the assignment obtained in the previous calls for $u_1, \ldots, u_{j-1}$. After this process, $\tau_\ell$ is an assignment of all the variables in $S$ that follows the distribution $\mu_{\Omega \Lambda}|_S$. This assignment has been computed in $O(|S| \log n)$ steps as we wanted. \hfill \Box

8 Mixing time of the Markov chain

In this section we study the mixing time of the $\rho$-uniform-block Glauber dynamics on the marked variables and prove Lemma 11. As explained in Section 2.2, in order to conclude rapid mixing of this Markov chain we apply the spectral independence framework, which has recently been extended to the $\rho$-uniform-block Glauber dynamics [8]. Traditionally in path coupling or spectral independence arguments one has to bound a sum of influences by a constant in order to obtain rapid mixing of the single-site Glauber dynamics. However, due to the presence of high-degree variables, an $O(1)$ upper bound seems unattainable in the random $k$-SAT formula setting; in the worst case paths of high-degree variable may significantly affect influences. This seems also to be the case for other random models, such as the hardcore model on random graphs [5]. Here we show that that sums of influences are at most $\varepsilon \log n$ for small $\varepsilon$ (Lemma 10). Even though this is generally not enough to conclude rapid mixing of the single-site Glauber dynamics, it turns out to be enough to conclude rapid mixing of the $\rho$-uniform-block Glauber dynamics for $\rho = \Theta(n)$. This section is divided as follows. In Section 8.1, we explain why bounded-degree methods to bound the mixing time of the Glauber dynamics fail to generalise from the bounded-degree $k$-SAT model to the random $k$-SAT model. In Section 8.2 we prove Lemmas 38 and 10. In Section 8.3 we prove Lemma 11.
8.1 Previous work on the Glauber dynamics for bounded-degree $k$-SAT formulas

In this section we explain why previously known arguments for showing rapid mixing of the Glauber dynamics on bounded-degree $k$-SAT formulas do not extend to the random $k$-SAT model. This section is not used in our work and may be skipped by a reader who just wants to understand our approach and result. The best result currently known on bounded-degree formulas is [26], where the authors show, for large enough $k$, how to efficiently sample satisfying assignments of $k$-CNF formulas in which their variables have maximum degree $\hat{\Delta} \leq C 2^{0.1742k}/k^3$, where $C > 0$ is a constant that does not depend on $k$.\footnote{In [26] the maximum degree $\hat{\Delta}$ of $\Phi$ is defined as the maximum over $c \in \mathcal{C}$ of the number of clauses that share a variable with $c$. Under this definition of $\hat{\Delta}$, their result holds for $\hat{\Delta} \leq C 2^{0.1742k}/k^2$.} Their result actually holds in the more general setting of atomic constrain satisfaction problems (albeit with a different bound on $\hat{\Delta}$). As part of their work, they show that the single-site Glauber dynamics on a set of marked variables mixes quickly. Their argument is restricted to atomic CSPs with bounded-degree and strongly exploits the properties of the Glauber dynamics in this setting. They study the optimal coupling of the single-site Glauber dynamics, we refer to [31] for the definition of coupling of Markov chains. In such a coupling the goal is to show that two copies of the chain starting from truth assignments differing in at least a marked variable (a so-called discrepancy) can be coupled in a small number of steps. Here it is crucial that the marginals of the marked variables are near $1/2$, so the optimal coupling generates new discrepancies with small probability. At this stage, the high-level idea to conclude rapid mixing of the Glauber dynamics is bounding the probability that the dynamics has not coupled by a product of probabilities, each corresponding to the event that a clause is unsatisfied at a certain time, and aggregating over all possible discrepancy sequences.

The fundamental observation in [26], based on the work on monotone $k$-CNF formulas presented in [24], is that if there is an update of a marked variable that generates a discrepancy in the chains, then there is another marked variable where the chains disagree that is connected to the former variable through a path of clauses, where consecutive clauses in the path share at least a variable. Moreover, each one of the clauses in this path is unsatisfied by at least one of the two copies of the chain. As a consequence, from a discrepancy at time $t$ one can find a sequence of discrepancies going back to time 0, and these discrepancies are joined by a path of clauses. Thus, the union bound over discrepancy sequences is essentially a union bound over paths of clauses with a particular time structure, where the same clause can be appear in the path several times. Extending this idea to the random $k$-SAT model presents two main issues. First of all, the number of discrepancy sequences of any given length may be too large due to the presence of bad clauses and the fact that they can repeatedly appear in the sequence. Moreover, it may be the case that these discrepancy sequences mostly consist of bad clauses, which are always unsatisfied in both chains and, thus, the probability that they are unsatisfied is not small. Interestingly, similar issues arise when directly extending the bounded-degree approach based on the coupling process of [32, 18] to our setting. In [18] the mixing time argument only succeeds when $\hat{\Delta} \leq 2^{k/20}/(8k)$ and is also based on a union bound over path of clauses that are unsatisfied or contain discrepancies after running a coupling process. However, very importantly, these paths of clauses are simple (clauses are not repeated) and the combinatorial structures appearing in the coupling process are less complex than the discrepancy sequences of [26]. This allowed the authors of [21] to exploit the expansion properties of random $k$-CNF formulas to analyse the coupling process of [32] on the random setting. Here we incorporate some novel ideas to the work of [21] in order to obtain a tighter analysis that leads to nearly linear running time of our sampling algorithm.

8.2 Spectral independence in the $k$-SAT model

In this section we prove Lemma 10. In order to bound the sum of influences of marked variables, we follow the coupling process technique that is standard in the literature [21, 32, 18]. In this work we introduce the concept of auxiliary variables in the coupling process and exploit the sparsity properties of logarithmic-sized
sets of clauses, which allows us to conclude a $2^{-\varepsilon n k} \log n$ spectral independence bound. The key idea is that if we progressively extend two assignments $X$ and $Y$ on auxiliary variables following the optimal coupling, at some point the formulas $\Phi^X$ and $\Phi^Y$ factorise in small connected components in spite of the presence of bad variables and, on top of that, $\Phi^X$ and $\Phi^Y$ share most of these connected components. Then we can bound influences between marked variables by analysing the connected components where $\Phi^X$ and $\Phi^Y$ differ. First, let us introduce some notation.

Let $\mu$ and $\nu$ be two distributions over the same space $\Omega$. A coupling $\tau$ of $\mu$ and $\nu$ is a joint distribution over $\Omega \times \Omega$ such that the projection of $\tau$ on the first coordinate is $\mu$ and the projection on the second coordinate is $\nu$. Recall that the total variation distance of $\mu$ and $\nu$ is defined by $d_{TV}(\mu, \nu) = \frac{1}{2} \sum_{x \in \Omega} |\mu(x) - \nu(x)|$. If a random variable $X$ has distribution $\mu$, we also write $d_{TV}(X, \nu)$ to mean $d_{TV}(\mu, \nu)$.

**Proposition 30** (Coupling lemma). Let $\tau$ be a coupling of $\mu$ and $\nu$. Then $d_{TV}(\mu, \nu) \leq \Pr_{(X,Y) \sim \tau}(X \neq Y)$. Moreover, there exists a coupling that achieves equality.

The coupling $\tau$ of $\mu$ and $\nu$ that minimises $\Pr_{(X,Y) \sim \tau}(X \neq Y)$ is called optimal. Let us now assume that $\mu$ and $\nu$ are Bernoulli distributions with parameters $0 \leq p \leq q \leq 1$ respectively, so $\Pr_{\mu}(X = 1) = p$ and $\Pr_{\nu}(Y = 1) = q$. The monotone coupling $\tau$ of $\mu$ and $\nu$ is defined as follows. We pick $U$ uniformly at random in $[0,1]$ and set $X = 1$ only when $U \leq p$ and $Y = 1$ only when $U \leq q$. For this coupling we have $\Pr_{(X,Y) \sim \tau}(X \neq Y) = q - p = d_{TV}(X,Y)$ and, hence, the monotone coupling is optimal.

Before presenting our coupling process, we show how we can bound a sum of influences between marked variables with the help of the coupling lemma. In all this section we fix a $k$-CNF formula $\Phi$ and a $\tau_0$-marking $(\nu_m, \nu_a, \nu_c)$ of $\Phi$. Given two assignments $\Lambda_1$ and $\Lambda_2$ on disjoint sets of variables, we denote by $\Lambda_1 \cup \Lambda_2$ the combined assignment on the union of their domains.

**Proposition 31.** Let $u \in \mathcal{V}_m$ and $\Lambda: S \to \{F,T\}$ with $S \subseteq \mathcal{V}_m \setminus \{u\}$. Let $(X,Y)$ be a coupling where $X$ follows the distribution $\mu_{\Omega\Lambda\cup u \to T}|_{\mathcal{V}_m}$ and $Y$ follows the distribution $\mu_{\Omega\Lambda\cup u \to F}|_{\mathcal{V}_m}$. Then

$$\sum_{v \in \mathcal{V}_m \setminus (S \cup \{u\})} |I^\Lambda(u \to v)| \leq \sum_{v \in \mathcal{V}_m \setminus (S \cup \{u\})} \Pr_{\nu_m}(X(v) \neq Y(v)). \quad (26)$$

**Proof.** Let $v \in \mathcal{V}_m$. Then for any $\omega \in \{F,T\}$, we have $\Pr(v \mapsto \omega|\Lambda, u \mapsto T) = \Pr(X(v) = \omega)$ and $\Pr(v \mapsto \omega|\Lambda, u \mapsto F) = \Pr(Y(v) = \omega)$. Thus, by the coupling lemma,

$$|I^\Lambda(u \to v)| = |\Pr(X(v) = T) - \Pr(Y(v) = T)| = d_{TV}(X(v), Y(v)) \leq \Pr(X(v) \neq Y(v)), \quad \Box$$

For two assignments $X$ and $Y$ on a subset of variables $V$, we say that $X$ and $Y$ have a discrepancy at $v \in V$ when $X(v) \neq Y(v)$. In [18] the authors manage to bound (26) by a constant that does not depend on $n$ when the considered formula has bounded degree. However, their argument breaks under the presence of high-degree variables due to the fact that we cannot control the number of bad clauses in a path of clauses unless the path has length at least $\Omega(\log n)$. Here instead we perform the coupling process developed in [21] over auxiliary variables, which accounts for the presence of bad clauses.

Before presenting our algorithm for the coupling process on auxiliary variables, let us describe some of the notation and structures that are used in this algorithm. Let $u \in \mathcal{V}_m$ and $\Lambda: S \to \{F,T\}$ with $S \subseteq \mathcal{V}_m \setminus \{u\}$. We start with two assignments $\tilde{X}$ and $\tilde{Y}$ that have a discrepancy at $u$ and agree with $\Lambda$ on $S$. In the coupling process we identify a set of failed clauses, denoted $\mathcal{F}_u \cup \mathcal{F}_a$. At each step of the process, we check if a clause is failed or extend the coupling to an auxiliary variable. It is important in our arguments that all clauses containing a discrepancy are failed, and that we make sure that the set of failed clauses is connected in $G_\Phi$ at all times. In order to achieve connectivity of failed clauses, at each step of the coupling process we only consider clauses that are adjacent to failed clauses in $G_\Phi$. For ease of reading, here we present a list of the structures that appear in our algorithm.
1. $\mathcal{V}_d$. Set of discrepancies, i.e., variables $v$ with $\hat{X}(v) \neq \hat{Y}(v)$.

2. $\mathcal{F}_d$. Set of all clauses containing a variable in $\mathcal{V}_d$. These are failed clauses.

3. $\mathcal{V}_{\text{set}}$. Set of variables that are assigned a value in the coupling.

4. $\mathcal{F}_u$. Set of clauses that have been considered by the coupling process, and are either bad or are unsatisfied by at least one of $\hat{X}$ and $\hat{Y}$ and have all their auxiliary variables in $\mathcal{V}_{\text{set}}$. These are failed clauses.

5. $\mathcal{C}_{\text{rem}}$. Set of clauses that have unassigned auxiliary variables or have not been explored yet.

Our coupling process on auxiliary variables is given in Algorithm 4.

**Algorithm 4** The coupling process on auxiliary variables

**Input:** A $k$-CNF formula $\Phi = (\mathcal{V}, \mathcal{C})$, an $r_0$-marking $\mathcal{M} = (\mathcal{V}_m, \mathcal{V}_a, \mathcal{V}_c)$, $u \in \mathcal{V}_m$ and $\Lambda : S \rightarrow \{F, T\}$ with $S \subseteq \mathcal{V}_m \setminus \{u\}$.

**Output:** a pair of assignments $\hat{X}, \hat{Y} : \mathcal{V}_{\text{set}} \rightarrow \{F, T\}$ for some set of variables $\mathcal{V}_{\text{set}}$ such that:

- $S \cup \{u\} \subseteq \mathcal{V}_{\text{set}} \subseteq S \cup \{u\} \cup \mathcal{V}_a$,
- $\hat{X}$ and $\hat{Y}$ agree with $\Lambda$ on $S$, $\hat{X}(u) = T$ and $\hat{Y}(u) = F$.

1. We fix two total orders $\leq_{\mathcal{V}}$ and $\leq_{\mathcal{C}}$ over the variables and clauses of $\Phi$. These are only relevant to have a pre-determined order in which clauses and variables are considered in this algorithm.

2. Initialise $\hat{X}$ and $\hat{Y}$ as $\Lambda$, and set $\hat{X}(u) = T$ and $\hat{Y}(u) = F$.

3. $\mathcal{V}_{\text{set}} \leftarrow S \cup \{u\}$, $\mathcal{V}_d \leftarrow \{u\}$, $\mathcal{F}_d \leftarrow \{c \in C : u \in \text{var}(c)\}$, $\mathcal{F}_u \leftarrow \emptyset$, $\mathcal{C}_{\text{rem}} \leftarrow C$.

4. while $\exists c \in \mathcal{C}_{\text{rem}} : \text{var}(c) \cap (\mathcal{V}_d \cup \text{var}(\mathcal{F}_u)) \neq \emptyset$ do

5. if $c$ is a bad clause then

6. Remove $c$ from $\mathcal{C}_{\text{rem}}$ and add $c$ to $\mathcal{F}_u$.

8. end if

9. if $c$ is a good clause and $(\text{var}(c) \cap \mathcal{V}_a) \setminus \mathcal{V}_{\text{set}} = \emptyset$ then

10. Remove $c$ from $\mathcal{C}_{\text{rem}}$ (as all auxiliary variables in $c$ have been set).

11. if $c$ is unsatisfied by at least one of $\hat{X}$ and $\hat{Y}$ then

12. Add $c$ to $\mathcal{F}_u$.

13. end if

14. end if

15. if $c$ is a good clause and $(\text{var}(c) \cap \mathcal{V}_a) \setminus \mathcal{V}_{\text{set}} \neq \emptyset$ then

16. Let $v$ be the smallest variable in $(\text{var}(c) \cap \mathcal{V}_a) \setminus \mathcal{V}_{\text{set}}$ (according to $\leq_{\mathcal{V}}$).

17. Extend $\hat{X}$ and $\hat{Y}$ to $v$ by sampling from the monotone coupling between the marginal distributions of $\mu_{\Omega\hat{X}}$ and $\mu_{\Omega\hat{Y}}$ on $v$, and add $v$ to $\mathcal{V}_{\text{set}}$.

18. if $\hat{X}(v) \neq \hat{Y}(v)$ then

19. Add $v$ to $\mathcal{V}_d$. Add all clauses containing $v$ to $\mathcal{F}_d$.

20. end if

21. end if

22. end while

23. return $(\hat{X}, \hat{Y})$.

First, we analyse the sets $\mathcal{V}_{\text{set}}$, $\mathcal{V}_d$, $\mathcal{F}_d$, $\mathcal{F}_u$ and $\mathcal{C}_{\text{rem}}$ and prove the connectivity property of $\mathcal{F}_d \cup \mathcal{F}_u$. In the rest of this section we fix the inputs of Algorithm 4 unless stated otherwise.
Proposition 32 (Properties of the coupling process). The coupling process in Algorithm 4 terminates eventually and, at the end of the process, the sets $V_{\text{set}}$, $V_d$, $F_u$, and $C_{\text{rem}}$ that are computed during the execution of the process possess the following properties:

1. We have $S \cup \{u\} \subseteq V_{\text{set}} \subseteq V_a \cup S \cup \{u\}$, $V_d = \{v \in V_{\text{set}} : \overline{X}(v) \neq \overline{Y}(v)\}$, and $F_d$ is the set of clauses containing a variable in $V_d$.

2. For all $c \in F_u$ we have $\text{var}(c) \cap V_a \subseteq V_{\text{set}}$ and $c$ is unsatisfied by at least one of $\overline{X}$ and $\overline{Y}$.

3. For all $c \in C_{\text{rem}}$, we have $\text{var}(c) \cap (V_d \cup \text{var}(F_u)) = \emptyset$.

4. For all $c \in C \setminus (C_{\text{rem}} \cup F_u)$, we have $\text{var}(c) \cap (V_d \cup \text{var}(F_u)) \neq \emptyset$, $\text{var}(c) \cap V_a \subseteq V_{\text{set}}$ and $c$ is satisfied by $\overline{X}$ and $\overline{Y}$.

5. The set $F_d \cup F_u$ is connected in $G_\Phi$.

Proof. Each iteration of the coupling procedure either removes a clause from $C_{\text{rem}}$, or samples the values $\overline{X}(v)$ and $\overline{Y}(v)$ for an auxiliary variable $v$ and adds $v$ to $V_{\text{set}} \subseteq V$. As $C_{\text{rem}}$ and $V$ are finite, the coupling terminates after a finite number of iterations. We prove the five properties in the statement separately. First, we note that the sets $V_{\text{set}}$, $V_d$, $F_d$, $F_u$ never decrease in size during the execution of Algorithm 4, whereas the set $C_{\text{rem}}$ never increases in size.

Property 1. Note that at the start of Algorithm 4 (line 3) this property holds. The result then follows from the fact that the sets $V_{\text{set}}$, $V_d$ and $F_d$ are only updated from line 15 to line 20 of Algorithm 4, and these steps preserve Property 1.

Property 2. This follows from the facts that the set $F_u$ is originally empty and is only extended in lines 7 and 12, and bad clauses do not contain auxiliary variables.

Property 3. This property follows from the fact that clauses that satisfy $\text{var}(c) \cap (V_d \cup \text{var}(F_u)) \neq \emptyset$ at some point are eventually removed from $C_{\text{rem}}$ in either line 7 (if they are bad) or in line 10 (if they are good, once all the auxiliary variables of the clause are in $V_{\text{set}}$).

Property 4. If $c \in C \setminus (C_{\text{rem}} \cup F_u)$, then $c$ has been removed from $C_{\text{rem}}$ in line 10 but it has not been added to $F_u$ in line 12, which proves this property.

Property 5. We note that at the start of the coupling process (line 3) $F_d \cup F_u$ is connected. Let us analyse every line of the algorithm where the sets $F_d$ and $F_u$ are enlarged. When it comes to $F_d$, this occurs in line 19 if this line is executed. Let $c$ be the clause considered in that iteration of the coupling process and let $v$ be the variable of $c$ considered in line 16. We recall that $\text{var}(c) \cap (V_d \cup \text{var}(F_u)) \neq \emptyset$ and $v \in (\text{var}(c) \cap V_a) \setminus V_{\text{set}}$. In line 19 we add all to $F_d$ all the clauses containing $v$. Let $C_v$ be the set of such clauses. Since $\emptyset \neq \text{var}(c) \cap (V_d \cup \text{var}(F_u)) \subseteq \text{var}(c) \cap \text{var}(F_d \cup F_u)$ and $c \in C_v$, we conclude that $F_d \cup F_u \cup C_v$ is connected as we wanted. When it comes to $F_u$, we add clauses in lines 7 and 12. In this case, we add a clause $c$ such that $\text{var}(c) \cap (V_d \cup \text{var}(F_u)) \neq \emptyset$, so $F_d \cup F_u \cup \{c\}$ is connected in $G_\Phi$. □

We can now prove our main result concerning the structure of $\Phi^\overline{X}$ and $\Phi^\overline{Y}$.

Lemma 33. Let $\overline{X}$ and $\overline{Y}$ be the assignments returned by Algorithm 4 and let $C_{\text{rem}}$ and $F_u$ be as in Proposition 32. There are sets of clauses $C_1 \subseteq C_{\text{rem}}$ and $C_2, C_3 \subseteq F_u$ such that $\Phi^\overline{X} = (V \setminus V_{\text{set}}, C_1 \cup C_2)$ and $\Phi^\overline{Y} = (V \setminus V_{\text{set}}, C_1 \cup C_3)$, where the variables in $V_{\text{set}}$ are removed from the clauses in $C_1, C_2, C_3$.

Proof. We determine the set of clauses that are unsatisfied by $\overline{X}$ or $\overline{Y}$ with the help of Proposition 32. We distinguish 3 disjoint cases:

- $c \in C_{\text{rem}}$. Then $\text{var}(c) \cap V_d = \emptyset$, so $\overline{X}$ and $\overline{Y}$ agree in all the variables in $\text{var}(C_{\text{rem}}) \cap V_{\text{set}}$. As a consequence, the restrictions of $\Phi^\overline{X}$ and $\Phi^\overline{Y}$ to $C_{\text{rem}}$ give rise to the same CNF formula. Note that
some of the clauses in $C_{rem}$ might be satisfied by both $\hat{X}$ and $\hat{Y}$, but they are never satisfied by only one of the two assignments.

- $c \in F_u$. Then $c$ is unsatisfied by at least one of $\hat{X}$ and $\hat{Y}$ and, thus, it appears in at least one of $\Phi^{\hat{X}}$ and $\Phi^{\hat{Y}}$. The clause $c$ may contain a variable $v \in \nu_d$.

- $c \notin C \setminus (C_{rem} \cup F_u)$. By Proposition 32, we have $\text{var}(c) \cap (\nu_d \cup \text{var}(F_u)) \neq \emptyset$ and $\text{var}(c) \cap \nu_a \subseteq \nu_{set}$.

  Since $c \notin F_u$, it follows that $c$ is satisfied by both $\hat{X}$ and $\hat{Y}$ and, thus, $c$ does not appear in any of the formulas $\Phi^{\hat{X}}$ and $\Phi^{\hat{Y}}$.

  We conclude that we can write $C^{\hat{X}} = C_1 \cup C_2$ and $C^{\hat{Y}} = C_1 \cup C_3$, where $C_1 \subseteq C_{rem}$ and $C_2, C_3 \subseteq F_u$ as we wanted. \hfill $\square$

In order to further analyse the probability distribution of the output of Algorithm 4, we introduce the following definition.

**Definition 34** (run, $\mathcal{R}(\Phi, M, u, \Lambda)$, $\tau_\mathcal{R}(\Phi, M, u, \Lambda)$, $\nu_{set}(R)$, $\nu_d(R)$, $F_u(R)$, $F_d(R)$, $C_{rem}(R)$). A run of Algorithm 4 is a sequence of all the random choices $(X(v), Y(v))$ made in line 17 when executing Algorithm 4. Let $\mathcal{R}(\Phi, M, u, \Lambda)$ be the set of all possible runs of Algorithm 4 for the inputs $\Phi, M, u, \Lambda$ and let $\tau_\mathcal{R}(\Phi, M, u, \Lambda)$ be the probability distribution that Algorithm 4 yields on $\mathcal{R}(\Phi, M, u, \Lambda)$. Each run $R \in \mathcal{R}(\Phi, M, u, \Lambda)$ determines the output $(\hat{X}, \hat{Y})$ and the sets $\nu_{set}(R), \nu_d(R)$, $F_u(R), F_d(R), C_{rem}(R)$ that are computed in Algorithm 4.

With the aim of applying Proposition 31, we extend the coupling $(\hat{X}, \hat{Y})$ to all marked and auxiliary variables.

**Definition 35** (The coupling $(X, Y)$). Let $R \in \mathcal{R}(\Phi, M, u, \Lambda)$ and let $(\hat{X}, \hat{Y})$ be the corresponding output of the run $R$. Let $\leq_V$ be a total order on the variables of $\Phi$ and let $v_1 \leq_V v_2 \leq_V \cdots \leq_V v_t$ be the variables in $(\nu_{m} \cup \nu_a) \setminus \nu_{set}$. We extend the assignments $\hat{X}, \hat{Y}$: $\nu_{set} \to \{F, T\}$ to $v_1, v_2, \ldots, v_t$ inductively (as follows) to obtain a coupling $(X, Y)$ such that $X$ follows the distribution $\mu_{\Omega^{\Lambda_{\nu_d} \cup \nu_{set}}} \mid V_{\nu_m \cup \nu_a} \setminus \nu_{set}$ and $Y$ follows the distribution $\mu_{\Omega^{\Lambda_{\nu_d} \cup \nu_{set}}} \mid V_{\nu_m \cup \nu_a} \setminus \nu_{set}$. Assume that $X$ and $Y$ are defined on $\nu_{set} \cup \{v_1, v_2, \ldots, v_{j-1}\}$ for $j \in \{1, 2, \ldots, t\}$. Then we sample $(X(v_j), Y(v_j))$ from the monotone coupling of the marginal distributions (on $v_j$) of $\mu_{\Omega^{\Lambda}}$ and $\mu_{\Omega^{\Lambda}}$.

**Remark 36.** When $R \in \mathcal{R}(\Phi, M, u, \Lambda)$ follows the probability distribution $\tau_\mathcal{R}(\Phi, M, u, \Lambda)$ (Definition 34), the pair of random assignments $(X, Y)$ of Definition 35 is a coupling of the distributions $\mu_{\Omega^{\Lambda_{\nu_d} \cup \nu_{set}}} \mid V_{\nu_m \cup \nu_a}$ and $\mu_{\Omega^{\Lambda_{\nu_d} \cup \nu_{set}}} \mid V_{\nu_m \cup \nu_a}$.

In Lemma 37 we bound the probabilities $\Pr(X(v) \neq Y(v) \mid R)$ for any $v \in (\nu_m \cup \nu_a) \setminus \nu_{set}(R)$ and $R \in \mathcal{R}(\Phi, M, u, \Lambda)$.

**Lemma 37.** Let $R \in \mathcal{R}(\Phi, M, u, \Lambda)$. Let $(X, Y)$ be the coupling of Definition 35. Then for any $v \in (\nu_m \cup \nu_a) \setminus \nu_{set}(R)$ we have $\Pr(X(v) \neq Y(v) \mid R) \leq 2^{-(r_0 + \delta)k + 1} / k$.

**Proof.** Let $\hat{X}$ and $\hat{Y}$ be the output of Algorithm 4 for the run $R$. Let $v_1, v_2, \ldots, v_t$ be the variables in $(\nu_m \cup \nu_a) \setminus \nu_{set}(R)$ in the order that they are considered in Definition 35. Let $j \in \{1, 2, \ldots, t\}$ and let $\Lambda', \Lambda''$: $\nu_{set}(R) \cup \{v_1, v_2, \ldots, v_{j-1}\} \to \{F, T\}$ be two assignments such that $\Lambda' \mid \nu_{set} = \hat{X}$ and $\Lambda'' \mid \nu_{set} = \hat{Y}$. When $X$ agrees with $\Lambda'$ and $Y$ agrees with $\Lambda''$, the values $X(v_j)$ and $Y(v_j)$ are sampled from the optimal/monotone coupling between the marginals on $v_j$ of the distributions $\mu_{\Omega^{\Lambda'}}$ and $\mu_{\Omega^{\Lambda''}}$. Let us denote
Applying the inequality (or Lemma 21) on the marginals of marked and auxiliary variables, we have

\[
\Pr(X(v_j) \neq Y(v_j)|\Lambda', \Lambda'') = d_{TV}(\nu_X, \nu_Y) = |\Pr(X(v_j) = T|\Lambda') - \Pr(Y(v_j) = T|\Lambda'')| \\
\leq |\Pr(X(v_j) = T|\Lambda') - 1/2| + |1/2 - \Pr(Y(v_j) = T|\Lambda'')| \\
\leq \exp\left(\frac{1}{k^{2(r_0+\delta)k}}\right) - 1.
\]

Applying the inequality \(e^z \leq 1+2z\) for \(z \in (0, 1)\), we find that \(\Pr(X(v_j) \neq Y(v_j)|\Lambda', \Lambda'') \leq 2^{-(r_0+\delta)k+1}/k\).

Thus, from the arbitrary choice of \(\Lambda', \Lambda''\) and the law of total probability we conclude that the bound \(\Pr(X(v_j) \neq Y(v_j)|R) \leq 2^{-(r_0+\delta)k+1}/k\) holds.

\(\square\)

Combining all the results presented up to this stage in the current section allows us to bound the sum

\[\sum_{v \in V_m \setminus (S \cup \{u\})} |I^\Lambda(u \to v)| \leq 2^{-(r_0+\delta)k+1}\E[|\mathcal{F}_u(R)|].\]

**Lemma 38.** There is an integer \(k_0\) such that for any \(k \geq k_0\) and any density \(\alpha\) with \(\alpha \leq \alpha_0\) the following holds w.h.p. over the choice of the random \(k\)-CNF formula \(\Phi = \Phi(k, n, \lfloor \alpha n \rfloor)\). Let \((V_m, V_a, V_e)\) be an \(r_0\)-marking of \(\Phi\), and let \(u \in V_m\) and \(\Lambda : S \to \{\text{F, T}\}\) with \(S \subseteq V_m \setminus \{u\}\). Then for a random run \(R\) of the coupling process on the auxiliary variables (Algorithm 4), we have

\[
\sum_{v \in V_m \setminus (S \cup \{u\})} |I^\Lambda(u \to v)| \leq 2^{-(r_0+\delta)k+1}\E[|\mathcal{F}_u(R)|].
\]

**Proof.** Let \((X, Y)\) be the coupling in Definition 35 for a (random) run \(R \sim \tau_R(\Phi, M, u, \Lambda)\) of Algorithm 4. We are going to show that

\[
\Pr(X(v) = Y(v)|R) = 1 \quad \text{for all } v \in V := (V_m \cup V_a) \setminus (V_{\text{set}}(R) \cup \var(F_u(R))).
\]

(27)

Let \(\widehat{X}, \widehat{Y} : V_{\text{set}}(R) \to \{\text{F, T}\}\) be the output of Algorithm 4 for the run \(R\). By Lemma 33 we conclude that we can write \(C^{\widehat{X}} = C_1 \cup C_2\) and \(C^{\widehat{Y}} = C_1 \cup C_3\), where \(C_1 \subseteq C_{\text{rem}}(R)\) and \(C_2, C_3 \subseteq F_u(R)\). Thus, the variables in \(V\) (see (27) for a definition of \(V\)) either appear in a clause in \(C_1\) or they are not present in any of the formulas \(\Phi^{\widehat{X}}\) and \(\Phi^{\widehat{Y}}\). Moreover, by Proposition 32, we have \(\var(c) \cap \var(c') = \emptyset\) for all \(c \in C_{\text{rem}}(R)\) and \(c' \in F_u(R)\). We conclude that the distributions \(\mu_\Omega|_V\) and \(\mu_{\Omega'}|_V\) agree – both are the uniform distribution over the satisfying assignments of the CNF formula \((V, C_1)\). Let \(v_1, v_2, \ldots, v_t\) be the variables in \(V\) in the order they are considered in the definition of the coupling \((X, Y)\). By induction on \(j \in \{1, 2, \ldots, t\}\), the marginals on \(v_j\) in Definition 35 are the same when coupling \(X(v_j)\) and \(Y(v_j)\) and, thus, \(X(v_j) = Y(v_j)\) for all \(j \in \{1, 2, \ldots, t\}\).

Since \(S \cup \{u\} \subseteq V_{\text{set}}(R) \subseteq S \cup \{u\} \cup V_a\), we have \(V_m \setminus V = S \cup \{u\} \cup (V_m \cap \var(F_u(R)))\). In light of Lemma 37 and (27), we find that

\[
\sum_{v \in V_m \setminus (S \cup \{u\})} \Pr(X(v) \neq Y(v)|R) \leq \sum_{v \in V_m \cap \var(F_u(R))} \Pr(X(v) \neq Y(v)|R) \leq \frac{2}{k} 2^{-(r_0+\delta)k}\var(F_u(R)).
\]

From \(|\var(F_u(R))| \leq k|F_u(R)|\) we conclude that

\[
\sum_{v \in V_m \setminus (S \cup \{u\})} \Pr(X(v) \neq Y(v)|R) \leq 2^{-(r_0+\delta)k+1}|F_u(R)|.
\]

(28)
In the rest of this proof we are going to aggregate (28) over \( R \in \mathcal{R}(\Phi, \mathcal{M}, u, \Lambda) \) with the aim of applying Proposition 31. Let \((X, Y)\) be the coupling in Definition 35 for a (random) run \( R \sim \tau_R(\Phi, \mathcal{M}, u, \Lambda) \) of Algorithm 4. We have

\[
\sum_{v \in \mathcal{V}_m \setminus (S \cup \{u\})} \Pr(X(v) \neq Y(v)) = \sum_{v \in \mathcal{V}_m \setminus (S \cup \{u\})} \sum_{R \in \mathcal{R}(\Phi, \mathcal{M}, u, \Lambda)} \Pr(R) \Pr(X(v) \neq Y(v)|R) \\
= \sum_{R \in \mathcal{R}(\Phi, \mathcal{M}, u, \Lambda)} \Pr(R) \sum_{v \in \mathcal{V}_m \setminus (S \cup \{u\})} \Pr(X(v) \neq Y(v)|R) \\
\leq 2^{-(\tau_0+\delta)k+1} \sum_{R \in \mathcal{R}(\Phi, \mathcal{M}, u, \Lambda)} \Pr(R)|\mathcal{F}_u(R)| \\
= 2^{-(\tau_0+\delta)k+1} \mathbb{E}[|\mathcal{F}_u(R)|].
\]

Finally, we note that we can indeed apply Proposition 31 to the restriction of \( X \) and \( Y \) on \( \mathcal{V}_m \) as \((X, Y)\) is a coupling of the distributions \( \mu_{\Omega \cup \mathcal{U} \rightarrow \mathcal{T}}|_{\mathcal{V}_m \cup \mathcal{V}_a} \) and \( \mu_{\Omega \cup \mathcal{U} \rightarrow \mathcal{T}}|_{\mathcal{V}_m \cup \mathcal{V}_a} \) (Remark 36). This finishes the proof. \( \square \)

In the remainder of this section we bound \( \mathbb{E}[|\mathcal{F}_u(R)|] \), which would complete our proof of Lemma 10 when combined with Lemma 38. In order to do this we exploit the fact that \( \mathcal{F}_u(R) \cup \mathcal{F}_d(R) \) is connected in \( G_R \) (Proposition 32), the local sparsity properties of random CNF formulas and the properties of the marking \((\mathcal{V}_m, \mathcal{V}_a, \mathcal{V}_e)\). It is important that the bound on \( \mathbb{E}[|\mathcal{F}_u(R)|] \) is \( \text{poly}(k) \log n \) in order to conclude fast mixing time of the \( \rho \)-uniform-block Glauber dynamics when applying the spectral independence framework. First, we bound the probability that some good clauses are failed in Algorithm 4. At first glance this seems to be a straightforward task thanks to the fact that the marginals of marked and auxiliary variables are close to \( 1/2 \) (see Proposition 6). However, for any good clauses \( c_1 \) and \( c_2 \), the events that \( c_1 \in \mathcal{F}_d(R) \cup \mathcal{F}_u(R) \) and \( c_2 \in \mathcal{F}_d(R) \cup \mathcal{F}_u(R) \) may not be independent; any value given to the variables in \( c_1 \) may affects the marginals of the variables in \( c_2 \) and whether these variables are considered by the coupling process or not. However, we show that, as long as \( c_1 \) and \( c_2 \) do not share good variables, these dependencies are not very strong and we can indeed bound the probability that \( c_1, c_2 \in \mathcal{F}_d(R) \cup \mathcal{F}_u(R) \) with a careful probability argument that analyses the coupling process step by step, see Lemma 42. With this in mind, we introduce the following definitions.

**Definition 39** \((\mathcal{R}_t(\Phi, \mathcal{M}, u, \Lambda), \mathcal{A}_{\leq t})\). For a positive integer \( t \), we let \( \mathcal{R}_t(\Phi, \mathcal{M}, u, \Lambda) \) be the set containing for each \( R \in \mathcal{R}(\Phi, \mathcal{M}, u, \Lambda) \) a tuple with the first \( \min\{t, \text{length}(R)\} \) entries of the sequence \( R \). That is, \( \mathcal{R}_t(\Phi, \mathcal{M}, u, \Lambda) \) is the set containing all possible sequences of the first \( t \) choices that Algorithm 4 makes in line 17. Note that if \( R \in \mathcal{R}(\Phi, \mathcal{M}, u, \Lambda) \) has \( \text{length}(R) \leq t \), then \( R \in \mathcal{R}_t(\Phi, \mathcal{M}, u, \Lambda) \). Each \( R_t \in \mathcal{R}_t(\Phi, \mathcal{M}, u, \Lambda) \) determines two partial assignments \( \tilde{X} \) and \( \tilde{Y} \) of marked and auxiliary variables that correspond to the assignments \( \hat{X} \) and \( \hat{Y} \) after \( \text{length}(R_t) \) iterations of line 17 following \( R_t \). Let \( \mathcal{A}_{\leq t} \) be the \( \sigma \)-algebra containing all the subsets of \( \mathcal{R}_t(\Phi, \mathcal{M}, u, \Lambda) \).

Intuitively, \( \mathcal{A}_{\leq t} \) contains all the possible events that may occur in the first \( t \) iterations of line 17, which is the only randomised operation in Algorithm 4. When bounding the probability that a clause is failed, we will express this event in terms of events concerning the values that \( \hat{X} \) and \( \hat{Y} \) take on its variables. This motivates Definition 40.

**Definition 40** \((D_v(j))\). We define the following events for variable \( v \in \mathcal{V}_a \) and a random run \( R \sim \tau(\Phi, \mathcal{M}, u, \Lambda) \) of Algorithm 4. Let \( D_v(1) \) be the event that \( v \in \mathcal{V}_{\text{set}}(R) \) and \( \hat{X}(v) \neq \hat{Y}(v) \). Let \( D_v(2) \) be the event that \( v \in \mathcal{V}_{\text{set}}(R) \) and \( \hat{X}(v) = \mathbb{F} \). Let \( D_v(3) \) be the event that \( v \in \mathcal{V}_{\text{set}}(R) \) and \( \hat{X}(v) = \mathbb{T} \). Let \( D_v(4) \) be the event that \( v \in \mathcal{V}_{\text{set}}(R) \) and \( \hat{Y}(v) = \mathbb{F} \). Let \( D_v(5) \) be the event that \( v \in \mathcal{V}_{\text{set}}(R) \) and \( \hat{Y}(v) = \mathbb{T} \).

31
Finally, in order to study the events $D_v(j)$ for $v \in V$ we will have to reason about the first time that a variable in $V$ is added to $\mathcal{V}_{\text{set}}(R)$, which motivates the following definition.

**Definition 41** ($\tau(V), f(V)$). For a set of auxiliary variables $V$, we let $\tau(V)$ be the random variable that takes the value $t$ if the first time that a variable in $V$ is added to $\mathcal{V}_{\text{set}}(R)$ in Algorithm 4 is the $t$-th time line 17 is executed, and we denote by $f(V)$ this variable. We set $\tau(V) = \infty$ if $V \cap \mathcal{V}_{\text{set}}(R) = \emptyset$, in which case $f(V)$ is not defined.

We now have all the tools that we need to analyse the coupling process step by step.

**Lemma 42.** Let $V \subseteq \mathcal{V}_n$ and let $i_v \in \{1, 2, 3, 4, 5\}$ for each $v \in V$. Let $h(1) = 2^{-(\delta + \tau_0)k + 1}/k$ and $h(i) = \exp(1/k)$ for $i \in \{2, 3, 4, 5\}$. Then, we have

$$\Pr_{R \sim \mathcal{R}(\Phi, M, u, \Lambda)} \left( \bigcap_{v \in V} D_v(i_v) \right) \leq \prod_{v \in V} h(i_v).$$

**Proof.** We are going to prove, for any positive integer $t$ and $A \in \mathcal{A}_{\leq t}$,

$$\Pr \left( \bigcap_{v \in V} D_v(i_v) \bigg| A, \tau(V) = t \right) \leq \prod_{v \in V} h(i_v). \tag{29}$$

The lemma will then follow from the arbitrary choice of $A$ and $t$ and the law of total probability.

We carry out the proof of (29) by induction on $M = |V|$. Equation (29) holds when $V$ is empty. Let us assume that (29) holds when $|V| < M$. Let $V$ be a set of auxiliary variables with $M = |V|$ and indexes $i_v$ for all $v \in V$, let $t$ be a positive integer and let $A \in \mathcal{A}_{\leq t}$. To simplify the notation, for each $w \in V$ we define $A_t(w, V) = A \cap [\tau(V) = t] \cap [f(V) = w]$. Then, we have

$$\Pr \left( \bigcap_{v \in V} D_v(i_v) \bigg| A, \tau(V) = t \right) \leq \sum_{w \in V} \Pr \left( f(V) = w \bigg| A, \tau(V) = t \right) \cdot \Pr \left( D_w(i_w) \bigg| A_t(w, V) \right).$$

We note that $\tau(V \setminus \{w\}) > t$ when conditioning on $\tau(V) = t$ and $f(V) = w$. Let $A' = A_t(w, V) \cap D_w(i_w)$. We have

$$\Pr \left( \bigcap_{v \in V \setminus \{w\}} D_v(i_v) \bigg| A' \right) = \sum_{j=t+1}^{\infty} \Pr \left( \tau(V \setminus \{w\}) = j \bigg| A' \right) \cdot \Pr \left( \bigcap_{v \in V \setminus \{w\}} D_v(i_v) \bigg| A', \tau(V \setminus \{w\}) = j \right).$$

By our induction hypothesis for $V \setminus \{w\}$, the condition $\tau(V \setminus \{w\}) = j$ and the event the event $A' \in \mathcal{A}_{\leq j}$, we find that

$$\Pr \left( \bigcap_{v \in V \setminus \{w\}} D_v(i_v) \bigg| A' \right) \leq \sum_{j=t+1}^{\infty} \Pr \left( \tau(V \setminus \{w\}) = j \bigg| A' \right) \prod_{v \in V \setminus \{w\}} h(i_v) \leq \prod_{v \in V \setminus \{w\}} h(i_v).$$

As a consequence, we obtain

$$\Pr \left( \bigcap_{v \in V} D_v(i_v) \bigg| A, \tau(V) = t \right) \leq \sum_{w \in V} \Pr \left( f(V) = w \bigg| A, \tau(V) = t \right) \cdot \Pr \left( D_w(i_w) \bigg| A_t(w, V) \right) \cdot \prod_{v \in V \setminus \{w\}} h(i_v).$$

32
We are going to show that \( \Pr(D_w(i_w) | A_t(w, V)) \leq h(i_w) \). Once we have proved this, the proof of (29) is completed by noting that \( \sum_{w \in V} \Pr(f(V) = w | A, \tau(V) = t) = 1 \).

Let us now bound \( \Pr(D_w | A_t(w, V)) \). Recall here that \( A_t(w, V) \) implies the event \( w \in \mathcal{V}_{\text{set}}(R) \). Recall also that \( A_t(w, V) \in \mathcal{A}_{\leq t} \), see Definition 39. For each \( R_t \in A_t(w, V) \subseteq R_t(\Phi, M, u, \Lambda) \), we are going to apply Proposition 6 and the fact that \( \hat{X}(w) \) and \( \hat{Y}(w) \) follow the optimal coupling between two marginal distributions on \( v \) of the form \( \mu_{\Omega'} \) and \( \mu_{\Omega''} \) for some assignments \( \Lambda', \Lambda'' \) on some marked and auxiliary variables that are determined by \( R_t \). Here it is important for applying Proposition 6 that the event \( A_t(w, V) \) is in \( \mathcal{A}_{\leq t} \), so every partial run \( R_t \in A_t(w, V) \) only gives information about what has happened in Algorithm 4 before \( w \) is added to \( \mathcal{V}_{\text{set}}(R) \). Thus, aggregating over all possible runs \( R_t \in A_t(w, V) \), we find that

\[
\max \left\{ \Pr(\hat{X}(w) = F | A_t(w, V)), \Pr(\hat{X}(w) = T | A_t(w, V)) \right\} \leq \frac{1}{2} \exp \left( \frac{1}{k^2(\delta + r_0)k} \right) \quad (30)
\]

where the probability is over the random run \( R \sim \tau_R(\Phi, M, u, \Lambda) \). The bound (30) also applies with \( \hat{Y} \) instead of \( \hat{X} \). In particular, we conclude that \( \Pr(D_w^1 | A_t(w, V)) \leq \exp(1/k)^2 / h(j) \) for all \( j \in \{2, 3, 4, 5\} \).

Moreover, using the definition of optimal coupling for two Bernoulli distributions, the probability that \( \hat{X}(w) \neq \hat{Y}(w) \) can be bounded as

\[
\Pr(\hat{X}(w) \neq \hat{Y}(w) | A_t(w, V)) = \Pr(\hat{X}(w) = T | A_t(w, V)) - \Pr(\hat{Y}(w) = T | A_t(w, V)) \leq \Pr(\hat{X}(w) = T | A_t(w, V)) - 1/2 + 1/2 - \Pr(\hat{Y}(w) = T | A_t(w, V)) \leq \exp \left( \frac{1}{k^2(\delta + r_0)k} \right) - 1.
\]

Hence, applying the bound \( e^z \leq 1 + 2z \) for \( z \in (0, 1) \) and the definition of the event \( D_{v_j}^1 \), we have \( \Pr(D_{v_j}^1 | A_t(w, V)) \leq 2 / (k^2(\delta + r_0)k) = h(1) \). This finishes the proof of (29). From the arbitrary choice of \( A \) and \( t \) and the law of total probability, the statement follows. \( \square \)

We can now bound the probability that some good clauses are failed with the help of Lemma 42.

**Lemma 43.** Let \( \Phi, u, \Lambda \) be the input of Algorithm 4. Let \( c_1, \ldots, c_\ell \in C_{\text{good}} \) such that the variable \( u \) does not appear in any of the clauses in \( c_1, \ldots, c_\ell \), and \( \text{var}(c_i) \cap \text{var}(c_j) \cap \mathcal{V}_{\text{good}} = \emptyset \) for all \( 1 \leq i < j \leq \ell \). Then, for \( R \sim \tau_R(\Phi, M, u, \Lambda) \), we have \( \Pr(c_1, \ldots, c_\ell \in \mathcal{F}_d(R) \cup \mathcal{F}_u(R)) \leq 2^{(-r_0k+4)\ell} \).

**Proof.** Let \( c_1, \ldots, c_\ell \) be some good clauses of \( \Phi \) as in the statement. The hypothesis that \( u \) does not appear in any of these clauses is necessary as if \( u \in \text{var}(c) \) then \( c \in \mathcal{F}_d(R) \) by definition. We consider a random run \( R \sim \tau_R(\Phi, M, u, \Lambda) \) of Algorithm 4 and let \( \hat{X}, \hat{Y} \) be the (random) output of Algorithm 4 for the run \( R \). For \( j \in \{1, 2, \ldots, \ell\} \), let \( F_j(1) \) be the event that there is \( v \in \text{var}(c_j) \cap \mathcal{V}_\Lambda \) such that \( v \in \mathcal{V}_{\text{set}}(R) \) and \( \hat{X}(v) \neq \hat{Y}(v) \), let \( F_j(2) \) be the event that \( \text{var}(c_j) \cap \mathcal{V}_\Lambda \subseteq \mathcal{V}_{\text{set}}(R) \) and \( c_j \) is unsatisfied by \( \hat{X} \), and let \( F_j(3) \) be the event that \( \text{var}(c_j) \cap \mathcal{V}_\Lambda \subseteq \mathcal{V}_{\text{set}}(R) \) and \( c_j \) is unsatisfied by \( \hat{Y} \). In light of Proposition 32, we have \( [c_1, \ldots, c_\ell \in \mathcal{F}_d(R) \cup \mathcal{F}_u(R)] = \bigcap_{j=1}^\ell (F_j(1) \cup F_j(2) \cup F_j(3)) \). We obtain

\[
\Pr \left( \bigcap_{j=1}^\ell (F_j(1) \cup F_j(2) \cup F_j(3)) \right) \leq \sum_{(i_1, i_2, \ldots, i_\ell) \in \{1, 2, 3\}^\ell} \Pr \left( \bigcap_{j=1}^\ell F_j(i_j) \right). \quad (31)
\]

We note that \( F_j(1) = \bigcup_{v \in \text{var}(c_j) \cap \mathcal{V}_\Lambda} D_v(1) \), see Definition 40. Let \( (i_1, i_2, \ldots, i_\ell) \in \{1, 2, 3\}^\ell \), and let \( I_1 = \{ j : i_j = 1 \} \), \( I_2 = \{ j : i_j = 2 \} \) and \( I_3 = \{ j : i_j = 3 \} \). If the event \( \bigcap_{j \in I_1} F_j(i_j) \) holds, then,
for each $j \in I_1$ there is a variable $u_j \in \var(c_j) \cap \mathcal{V}_a$ such that $D_{u_j}(1)$ holds. Thus, for the set of tuples $T = \prod_{j \in I_1} (\var(c_j) \cap \mathcal{V}_a)$, where $\prod$ here denotes the cartesian product of sets, we have

$$\bigcap_{j \in I_1} F_j(i_j) = \bigcup_{(u_1,u_2,\ldots,u_{|I_1|}) \in T} \cap_{j \in I_1} D_{u_j}(1). \quad (32)$$

Now we explain how we bound $\Pr\left(\left(\bigcap_{j \in I_2 \cup I_3} F_j(i_j)\right) \cap \left(\bigcap_{j \in I_1} D_{u_j}(1)\right)\right)$ for a tuple $(u_1, u_2, \ldots, u_{|I_1|}) \in T$. We are going to show that

$$\Pr\left(\left(\bigcap_{j \in I_2 \cup I_3} F_j(i_j)\right) \cap \left(\bigcap_{j \in I_1} D_{u_j}(1)\right)\right) \leq \left(\frac{\exp(1/k)}{2}\right)^{(k-3)r_0|I_2 \cup I_3|} \left(\frac{2}{k^2(r_0+\delta)k}\right)^{|I_1|} \quad (33)$$

The proof of (33) is not as straightforward as it may seem at first glance due to the dependencies among the events $F_j(i_j)$, $D_{u_j}(1)$. The key idea is re-writing the LHS of (33) as in the statement of Lemma 42. Indeed we note that for each $j \in I_2$ and for each variable $v \in \var(c_j) \cap \mathcal{V}_a$, the event $F_j(2)$ implies that there is $i_v \in \{2,3\}$ such that $D_v(i_v)$ holds, concluding $F_j(2) = \bigcap_{v \in \var(c_j) \cap \mathcal{V}_a} D_v(i_v)$, see Definition 40. Analogously, for each $j \in I_3$ and for each variable $v \in \var(c_j) \cap \mathcal{V}_a$, we find $i_v \in \{4,5\}$ such that $F_j(3) = \bigcap_{v \in \var(c_j) \cap \mathcal{V}_a} D_v(i_v)$. Therefore, we have

$$\left(\bigcap_{j \in I_2 \cup I_3} F_j(i_j)\right) \cap \left(\bigcap_{j \in I_1} D_{u_j}(1)\right) = \bigcap_{v \in V_f} D_v(i_v), \quad (34)$$

where $V_f$ contains exactly all the auxiliary variables in the clauses $c_j$ with $j \in I_2 \cup I_3$ and the variables $u_1, u_2, \ldots, u_{|I_1|}$. Recall now that each good clause contains at least $r_0(k-3)$ auxiliary variables, and, thus, the bound given in (33) follows from (34) and Lemma 42. Combining (33), (32) and (31), and counting the number of tuples in $T$, we conclude that

$$\Pr\left(\bigcap_{j=1}^{\ell} (F_j(1) \cup F_j(2) \cup F_j(3))\right) \leq \sum_{(i_1,i_2,\ldots,i_\ell) \in \{1,2,3\}^\ell} k^{|I_1|} \left(\frac{\exp(1/k)}{2}\right)^{(k-3)r_0|I_2 \cup I_3|} \left(\frac{2}{k^2(r_0+\delta)k}\right)^{|I_1|}$$

$$\leq \sum_{(i_1,i_2,\ldots,i_\ell) \in \{1,2,3\}^\ell} \left(\frac{e^{2^{3r_0}}}{2^{kr_0}} + \frac{e^{2^{3r_0}}}{2^{kr_0}} + \frac{2}{2^{(r_0+\delta)k}}\right)^\ell,$$

where we used the multinomial theorem. The result now follows from $2e^{2^{3r_0}} + 2 \leq 2^4$. \hfill \qed

Following [21] and motivated by Lemma 43, we introduce the combinatorial structure that we use in our proof of Lemma 10 to bound the expected number of failed clauses.

**Definition 44** ($G^{\leq k}$, $D_3(G_{\Phi}, c, \ell)$). For a graph $G = (V, E)$ and a positive integer $k$, let $G^{\leq k}$ be the graph with vertex set $V$ in which vertices $u$ and $v$ are connected if and only if there is a path from $u$ to $v$ in $G$ of length at most $k$. Given the graph $G_{\Phi}$, a clause $c$ and a positive integer $\ell$, let $D_3(G_{\Phi}, c, \ell)$ be the set of subsets $T \subseteq V(G_{\Phi})$ such that the following holds:

1. $|T| = \ell$ and $c \in T$;
2. for any $c_1, c_2 \in T$, $\var(c_1) \cap \var(c_2) \cap \mathcal{V}_{\text{good}} = \emptyset$;
3. the graph $G_{\Phi}^{\leq 3}[T]$, which is the subgraph of $G_{\Phi}^{\leq 3}$ induced by $T$, is connected;
4. we have \(|T \cap C_{\text{good}}| \geq (1 - 8/k)^\ell\).

In [21] the authors consider connected sets in \(G_\Phi^\leq 4\) instead of \(G_\Phi^\leq 3\). Here we manage to perform our union bound on \(D_3(G_\Phi, c, \ell)\) thanks to the fact that the set of failed clauses is connected in our refinement of the coupling process.

**Lemma 45** ([21, Corollary 8.19] for \(G^\leq 3\)). Let \(G = (V, E)\) be a connected graph, let \(v \in V\) and let \(\ell\) be a positive integer. Let \(n_{G, \ell}(v)\) denote the number of connected induced subgraphs of \(G\) with size \(\ell\) containing \(v\). Then, for \(\ell' = \min\{3\ell, |V|\}\), we have \(n_{G, \ell'}(v) \leq 2^{3\ell} n_{G, \ell}(v)\).

**Proof.** Let \(T\) be a connected subgraph of \(G^\leq 3\) with size \(\ell\) containing \(v\). We claim that, for all positive \(\ell\), we can find a connected subset \(H\) of \(G\) with size \(\ell'' = \min\{3\ell, |V|\}\) containing \(T\). The proof is straightforward by induction on \(\ell\), see [21, Lemma 8.18] for the analogous result on \(G^\leq 4\). We note that there are at most \((\ell')^3\) subsets \(T\) of \(H\) containing \(v\) that could be mapped to \(H\) by the previous construction. Hence, we conclude that \(n_{G, \ell'}(v) \leq 2^{3\ell} n_{G, \ell}(v)\) as we wanted. \(\square\)

**Lemma 46** ([21, Lemma 7.9] for \(D_3(G_\Phi, c, \ell)\)). Let \(\ell\) be an integer which is at least \(\log n\). W.h.p. over the choice of \(\Phi\), every clause \(c \in C_{\text{good}}\) has the property that the size of \(D_3(G_\Phi, c, \ell)\) is at most \((18k^2\alpha)^{3\ell}\).

**Proof.** This follows from bounding the number of connected sets of size \(\ell\) in \(G_\Phi^\leq 3\) that contain \(c\) by combining Lemmas 27 and 45. \(\square\)

We have now all the tools that we need to bound the expected number of failed clauses in the coupling process given in Algorithm 4 and complete the proof of Lemma 10.

**Lemma 10.** There is an integer \(k_0 \geq 3\) such that for any integer \(k \geq k_0\) and any density \(\alpha\) with \(\alpha \leq 2^{-r_0 k^3}/k^3\) the following holds. W.h.p. over the choice of the random \(k\)-CNF formula \(\Phi = \Phi(k, n, [\alpha n])\), for any \(r_0\)-marking \((\mathcal{V}_m, \mathcal{V}_a, \mathcal{V}_c)\) of \(\Phi\), the distribution \(\mu_{(\mathcal{V}_m)\mathcal{V}_a}\) is \((2^{-r_0 k \log n})\)-spectrally independent.

**Proof.** Let \(u \in \mathcal{V}_m\) and \(\Lambda : S \to \{F, T\}\) with \(S \subseteq \mathcal{V}_m \setminus \{u\}\). First of all, we apply Lemma 38 to bound \(\sum_{v \in \mathcal{V}_m \setminus (S \cup \{u\})} |\mathcal{I}_{\Lambda}(u \to v)| \leq 2^{-r_0 + k + 1} \mathbb{E}(|\mathcal{F}_u(R)|),\) where \(R \sim \tau_R(\Phi, \mathcal{M}, u, \Lambda)\). In the rest of this proof we show that \(\mathbb{E}(|\mathcal{F}_u(R)|) \geq 2^{k - 4k \log n} \leq O(1/n)\) and, thus, for large enough \(n\), \(\mathbb{E}(|\mathcal{F}_u(R)|) \leq k^4 \log n\). Putting all this together, and using the fact that \(8k^4 \leq 2^{k^2}\) for large enough \(k\) (where \(\delta = 0.00001\)) we obtain the bound \(\sum_{v \in \mathcal{V}_m \setminus (S \cup \{u\})} |\mathcal{I}_{\Lambda}(u \to v)| \leq 2^{-r_0 k^4} \log n \leq 2^{-r_0 k^4} \log n\) and, thus, the result would follow.

So to finish we just need to show that, w.h.p. over the choice of \(\Phi\), \(\mathbb{E}(|\mathcal{F}_u(R)|) \geq 2^{k - 4k \log n} \leq O(1/n)\). Let \(L = [2^{k - 4k \log n}]\) and let \(\ell = [0.5k^4 \log n]\). First, we are going to show that, w.h.p. over the choice of \(\Phi\) the following holds:

\[
\text{if } Z \subseteq C \text{ is connected and } |Z| = L, \text{ then } \exists c \in Z \cap C_{\text{good}} \text{ and } T \in D_3(G_\Phi, c, \ell) \text{ with } T \subseteq Z. \quad (35)
\]

In order to prove (35), we are going to find a large independent set of \(Z \cap C_{\text{good}}\), and we are going to extend it with some clauses in \(Z \cap C_{\text{bad}}\) to obtain \(T \in D_3(G_\Phi, c, \ell)\). We need three results that hold w.h.p. over the choice of \(\Phi\): Lemmas 15, 25 and 24. We note that we can apply Lemma 15 as our density satisfies \(\alpha \leq 2^{-r_0 k^3}/k^3 \leq 2^{(r_0 - 2\delta)k}/k^3\), where \(\delta = 0.00001\). For \(Z\) as in (35) we have \(|Z| \geq 2^{k^4 \log n}\) and, so by Lemma 25, we find that \(|\var(Z)| \geq 2^{k^4 \log n}\). Thus, in light of Lemma 15, we conclude that \(|Z \cap C_{\text{good}}| \geq (1 - 1/k)\frac{|Z|}{k}\) and \(|Z \cap C_{\text{bad}}| \leq |Z|/k\). From Lemma 24, w.h.p. over the choice of \(\Phi\), all connected sets of clauses with size at most \(4k^4 \log n\) have tree-excess at most \(t := \max\{1, 8k^4 \log (ek^2\alpha)\}\). Thus, we can find \(U \subseteq Z \cap C_{\text{good}}\) such that \(U\) is a forest (disjoint union of trees) and \(|U| \geq (1 - 1/k)\frac{|Z|}{k} - t\). In particular, \(U\) is bipartite, so there is \(I \subseteq U\) such that \(\var(e) \cap \var(e') = \emptyset\) for all \(c, c' \in I\) and \(|I| \geq \text{...} \).
\[ |U|/2 \geq (1 - 1/k)L/2 - t/2 \geq \frac{1}{2}k^4 \log n, \] where the last inequality holds for large enough \( n \). Let \( I' \) be an independent set of \( Z \cap C_{\text{good}} \) with the largest possible size. Then we have shown that \( |I'| \geq \ell = \lceil \frac{1}{2}k^4 \log n \rceil \).

We claim that the set \( T' := I' \cup (Z \cap C_{\text{bad}}) \) is connected in \( (G_{\Phi}[Z])^{\leq 3} \), where \( G_{\Phi}[Z] \) is the subgraph of \( G_{\Phi} \) induced by \( Z \). Assume for contradiction that \( T' \) is not connected in \( (G_{\Phi}[Z])^{\leq 3} \). In this case, we can write \( T' = S_1 \cup S_2 \) such that for all \( c_1 \in S_1 \) and \( c_2 \in S_2 \), the shortest path between \( c_1 \) and \( c_2 \) through clauses in \( Z \) has length at least 4. Let \( (c_1, c_2) \in S_1 \times S_2 \) be the pair with the shortest path in \( Z \), and let this path be \( c_1 = e_1, e_2, \ldots, e_j = c_2 \). Then \( j \geq 5 \) and \( e_2, \ldots, e_{j-1} \in Z \setminus \Phi \). Moreover, we find that \( \text{var}(e_3) \cap \text{var}(e) = \emptyset \) for all \( c \in T' \) as otherwise \( e_1, e_2, \ldots, e_j \) would not be the shortest path between \( S_1 \) and \( S_2 \). Moreover, since \( T' \) contain all bad clauses in \( Z \), we conclude that \( e_3 \) is a good clause. It follows that \( I' \cup \{e_3\} \) is an independent set of good clauses of \( Z \), which contradicts the fact that \( I' \) has largest possible size among such sets.

Finally, as \( |T'| \geq \ell \), we can find a good clause \( c \) and a subset \( T \) of \( T' \) with size \( \ell \) such that \( c \in T, T \) is connected in \( G_{\Phi}^{\leq 3} \) and \( |T \cap C_{\text{bad}}| \leq |Z \cap C_{\text{bad}}| \leq L/k \leq 8\ell/k \). We conclude that \( T \in \mathcal{D}_3(G_{\Phi}, c, \ell) \). This finishes the proof of (35).

In the rest of the proof we use (35) to bound \( \Pr(|\mathcal{F}_u(R)| \geq L) \). Recall that the set of failed clauses \( \mathcal{F}_d(R) \cup \mathcal{F}_u(R) \) is connected (Proposition 32). If \( |\mathcal{F}_u(R)| \geq L \), then there is \( Z \subseteq \mathcal{F}_d(R) \cup \mathcal{F}_u(R) \) with \( |Z| = L \) such that \( Z \) is connected in \( G_{\Phi} \), and, thus, we can find \( c \) and \( T \) as in (35). We have shown that the event \( |\mathcal{F}_u(R)| \geq L \) is contained in the event that there is a good clause \( c \) and \( T \in \mathcal{D}_3(\Phi, c, \ell) \) such that \( T \subseteq \mathcal{F}_d(R) \cup \mathcal{F}_u(R) \). As a consequence, we have

\[
\Pr[|\mathcal{F}_u(R)| \geq L] \leq \sum_{c \in C} \sum_{T \in \mathcal{D}_3(\Phi, c, \ell)} \Pr[T \subseteq \mathcal{F}_d(R) \cup \mathcal{F}_u(R)] \
\leq \sum_{c \in C} \sum_{T \in \mathcal{D}_3(\Phi, c, \ell)} \Pr[T \cap C_{\text{good}} \subseteq \mathcal{F}_d(R) \cup \mathcal{F}_u(R)].
\]

We note that for any \( T \in \mathcal{D}_3(\Phi, c, \ell) \) there is at most one good clause \( c' \) that contains the marked variable \( u \). Thus, by definition of \( \mathcal{D}_3(\Phi, c, \ell) \), there are at least \((1 - 8/k)\ell - 1\) good clauses in \( T \) that do not contain the variable \( u \). Hence, we can apply Lemma 46 on the size of \( \mathcal{D}_3(\Phi, c, \ell) \) and Lemma 43 on the probability of good clauses (that do not share good variables) failing to further obtain

\[
\Pr[|\mathcal{F}_u(R)| \geq L] \leq m \left(18k^2\alpha\right)^{3\ell} 2^{-(r \cdot \ell - 4)(1 - 8/k)\ell - 1}.
\]

In what follows it is essential that \( \alpha \leq 2^{r \cdot \ell / 3} / k^3 \), and this is the only proof in this paper where we need this bound on the density – other proofs only require the less restrictive bound \( \alpha \leq 2^r k \) for \( r = 0.1178 \). Thus, we conclude that

\[
\Pr[|\mathcal{F}_u(R)| \geq L] \leq m \left(18^{3 \ell} k^3 2^{r \cdot \ell - 4}\right)^{\ell} 2^{r \cdot \ell - 4}.
\]

Finally, for large enough \( k \) we find that \( \Pr[|\mathcal{F}_u(R)| \geq L] \leq me^{-\ell 2^{r \cdot \ell}} \leq mn^{-0.5k^4} 2^{r \cdot \ell} = O(1/n) \) as we wanted.

\[8.3\] Mixing of the \( \rho \)-uniform-block Glauber dynamics

Finally, we combine the results in this section with Lemma 9 to complete the proof of Lemma 11.

Remark 47. The distribution \( \mu_{\Omega}|_{V_u} \) on assignments of the marked variables (Definition 7) is \( b \)-marginally bounded for \( b = 1 - (1/2) \exp(1/k) \) by Proposition 6 (or, equivalently, Lemmas 20 and 21). Since \( \exp(1/k) \leq 1 + 2/k, \) we have \( b \geq 1/2 - 1/k \geq 1/e \) for \( k \geq 8 \).
Lemma 11. There is a function $k_0(\theta) = \Theta(\log(1/\theta))$ such that, for any $\theta \in (0,1)$, for any integer $k \geq k_0(\theta)$ and any density $\alpha$ with $\alpha \leq 2^{0.039k}$ the following holds. W.h.p. over the choice of the random $k$-CNF formula $\Phi = \Phi(k,n,\lceil \alpha n \rceil)$, for any $r_0$-marking $(V_m, V_a, V_c)$ of $\Phi$ and for $\rho = \lfloor 2^{-k-1} |V_m| \rfloor$, the $\rho$-uniform-block Glauber dynamics for updating the marked variables has mixing time $T_{\text{mix}}(\rho, \varepsilon/2) \leq T := \lfloor 2^{2k+3} n^\theta \log \frac{2n}{\varepsilon^2} \rfloor$.

Proof. In view of Lemma 10, as $\alpha \leq 2^{0.039k} \leq 2^{r_0 k/3}/k^3$ for large enough $k$, w.h.p. over the choice of $\Phi$, the distribution $\mu_{|V_m}$ is $\eta$-spectrally independent for $\eta = 2^{-r_0 k} \log n$. Moreover, this distribution is $b$-marginally bounded for $b = 1/e$ when $k \geq 8$. We are going to apply Lemma 9 with $V = V_m$, $\mu = \mu_{|V_m}$, $M = |V_m|$ and $\kappa = 2^{-k-1}$. First, we check that the hypothesis $M \geq \frac{2}{\kappa}(4\eta/b^2 + 1)$ of Lemma 9 holds. By Corollary 23, we have $M \geq (r_0 - \delta)(k\alpha/\Delta)n = \Omega(n)$, so $M \geq \frac{2}{\kappa}(4\eta/b^2 + 1)$ holds for large enough $n$ as $\frac{2}{\kappa}(4\eta/b^2 + 1) = O(\log n)$. Hence, we can apply Lemma 9 to obtain

$$T_{\text{mix}}(\rho, \varepsilon/2) \leq \left[ C_\rho \frac{M}{\rho} \left( \log \log \frac{1}{\mu_{\text{min}}} + \log \frac{2}{\varepsilon^2} \right) \right],$$

where $C_\rho = (2/\kappa)^{4\eta/b^2+1}$. We have

$$C_\rho = \exp \left( (\log 2)(k + 2)(\frac{4\eta}{b^2} + 1) \right) \leq 2^{k+2} \exp \left( \frac{(\log 2)(\log n)(k + 2)e^2}{2^{r_0 k}} \right),$$

so there exists a function $k_0(\theta) = \Theta(\log(1/\theta))$ such that when $k \geq k_0(\theta)$, we have $C_\rho \leq 2^{k+2} n^\theta$. In light of Remark 47, we have $\mu_{\text{min}} \geq b^M$, so $\log \log(1/\mu_{\text{min}}) \leq \log(M \log(1/b)) = \log M$ as $b = 1/e$. Thus, we conclude that

$$T_{\text{mix}}(\rho, \varepsilon/2) \leq \left[ 2^{2k+3} n^\theta \left( \log M + \log \frac{2}{\varepsilon^2} \right) \right] \leq \left[ 2^{2k+3} n^\theta \log \frac{2n}{\varepsilon^2} \right].$$

\qed

9 Proof of Theorem 1

In this section we complete the proof of Theorem 1. The proofs in this section do not present any challenging steps. In fact, they amount to combining the main technical results that have already been proved in this work. We start by showing that the calls to the method Sample in Algorithm 1 are unlikely to ever return error, that is, the connected components of $G_{\Phi^A}$ have size at most $2k^4(1 + \xi) \log(n)$ almost every time the method is called. As pointed out in our proof outline, this is a straightforward consequence of Lemma 13 and the fact that the probability distribution of the output of the Glauber dynamics is $(1/k)$-uniform (Corollary 22).

Lemma 48. Let $\theta \in (0,1)$. There is an integer $k_0 \geq 3$ such that, for any integers $k \geq k_0$, $\xi \geq 1$ and any density $\alpha \leq 2^k$, the following holds w.h.p. over the choice of $\Phi = \Phi(k,n,\lceil \alpha n \rceil)$. In the execution of Algorithm 1 with input $\Phi$, with probability at least $1 - n^{-3\xi}$ over the random choices made by Algorithm 1, every time that the algorithm calls the method Sample($\Phi^A, S$), the connected components of $G_{\Phi^A}$ have size at most $2k^4(1 + \xi) \log(n)$.

Proof. Let $\varepsilon = n^{-\xi}$ and let $T = \lfloor 2^{2k+3} n^\theta \log \frac{2n}{\varepsilon^2} \rfloor$ be the mixing time established in Lemma 11. We assume that $k$ is large enough so that $2^k \leq \alpha_0 = 2(r_0 - 2\delta)k/k^3$. Algorithm 1 calls the method Sample exactly $T + 1$ times in total: $T$ times in line 7 (when simulating the $\rho$-uniform-block Glauber dynamics) and one time in line 10 to extend the assignment $X_T$ of marked variables to all variables.

Let $t \in \{0, 1, \ldots, T\}$ and let $\pi_t$ be the probability distribution of $X_t$, where $X_t$ is the state of the $\rho$-block-uniform Glauber dynamics on the marked variables described in Algorithm 1 after $t$ steps. Recall
that $\rho = [2^{-k-1}|\mathcal{V}_m|]$ and that $X_0$ is chosen uniformly at random. First, we focus on the case $t < T$. We are going to apply Lemma 13 with $a = 2k^4$, $b = 2\alpha(1 + \xi)$, $V = \mathcal{V}_m$, $\mu = \pi_t$ and this choice of $\rho$. The set $\mathcal{V}_m$ is $r_0$-distributed by the definition of $r_0$-marking (Definition 4). Moreover, $\pi_t$ is $(1/k)$-uniform by Corollary 22, and we have $\rho \leq |\mathcal{V}_m|/2^k$. Hence, we can indeed apply Lemma 13. Consider the following experiment described in Lemma 13 for $L = \lfloor a(1 + \xi) \log n \rfloor$, which satisfies $a \log n \leq L \leq b \log n$. First, draw $S \subseteq \mathcal{V}_m$ from the uniform distribution $\tau$ over subsets of $\mathcal{V}_m$ with size $\rho$. Then, sample an assignment $\Lambda_{t+1}$ from $\mu|_{\mathcal{V}_m \backslash S}$, the marginal of $\mu$ on $\mathcal{V}_m \backslash S$. Denote by $\mathcal{F}$ the event that there is a connected set of clauses $Y$ of $\Phi$ with $|Y| \geq L$ such that all clauses in $Y$ are unsatisfied by $\Lambda_{t+1}$. Then we have

$$\Pr_{S \sim \tau}\left(\Pr_{\Lambda_{t+1} \sim \pi_t|_{\mathcal{V}_m \backslash S}}(\mathcal{F}) \leq 2^{-\delta kL}\right) \geq 1 - 2^{-\delta kL}.\quad (36)$$

Alternatively, this experiment is the same as first sampling an assignment $X_t$ of all variables in $\mathcal{V}_m$ from $\pi_t$, and then restricting the assignment to a random set $S \sim \tau$, obtaining $\Lambda_{t+1}$. Note that this exact experiment occurs before calling the method Sample in the $t$-th step of the $\rho$-uniform-block Glauber dynamics in Algorithm 1. Thus, in light of (36), the probability that in step $t+1$ of the execution of Algorithm 1 the graph $G_{\Phi, \Lambda_{t+1}}$ has a connected component with size at least $L$ is at most $2^{-\delta kL} + 2^{-\delta kL}$, where the first $2^{-\delta kL}$ comes from the probability of choosing a wrong set $S \sim \tau$ in (36) and the second $2^{-\delta kL}$ comes from the bound on the probability of the event $\mathcal{F}$ once we have chosen $S$. We have shown that with probability at least $1 - 2 - 2^{-\delta kL}$, all the connected components of the graph $G_{\Phi, \Lambda_t}$ appearing in step $t+1$ of the execution of Algorithm 1 have size less than $L$. We have $2^{-\delta kL} \leq n^{-\delta k(1+\xi)\log^2} \leq n^{-5\xi}$ for large enough $k$, so the probability that Sample returns error at step $t+1$ is at most $n^{-5\xi}$. The case $t = T$ is analogous, the only difference here is that we call Sample on $\Phi^{X_T}$, where $X_T \sim \pi_T$ is an assignment of all marked variables, so we apply Lemma 13 with $\rho = 0$.

Finally, we carry out a union bound over $t \in \{0, 1, \ldots, T\}$, so the probability that any of the calls to Sample returns error is at most $(T+1)n^{-5\xi} \leq n^{-3\xi}$ for large enough $n$ as $T = O(n^\theta \log n) = O(n \log n)$.

Once we have established Lemmas 11, 14, and 48, the proof of Theorem 1 follows as below.

**Theorem 1.** For any real $\theta \in (0, 1)$, there is $k_0 \geq 3$ with $k_0 = O(\log(1/\theta))$ such that, for any integers $k \geq k_0$ and $\xi \geq 1$, and for any positive real $\alpha \leq 2^{0.039k}$, the following holds.

There is an efficient algorithm to sample from the satisfying assignments of a random $k$-CNF formula $\Phi = \Phi(k, n, [\alpha n])$ within $n^{-\xi}$ total variation distance of the uniform distribution. The algorithm runs in time $O(n^{1+\theta})$, and succeeds w.h.p. over the choice of $\Phi$.

**Proof.** Let $k_0(\theta) = \Theta(\log(1/\theta))$ be large enough so that, for all integers $k \geq k_0(\theta)$, $\xi \geq 1$ and all densities $\alpha \leq 2^{0.039k}$, the conclusions of Lemmas 11, 14, and 48 hold w.h.p. over the choice of the random $k$-CNF formula $\Phi = \Phi(k, n, [\alpha n])$. These lemmas are enough to analyse Algorithm 1 and tackle this proof. We analyse the distribution $\mu_{\text{alg}}$ of the output of Algorithm 1. This distribution outputs either a satisfying assignment of the input formula $\Phi$ or error. Let $\varepsilon = n^{-\xi}$. Let $\mathcal{E}$ be the event that running Algorithm 1 outputs error. This happens with probability at most $\varepsilon/4$ when computing the marking $(\mathcal{V}_m, \mathcal{V}_a, \mathcal{V}_c)$ in line 2 of the algorithm, and in lines 7 and 10 if the method Sample$(\hat{\Phi}, S)$ returns error, which occurs when $G_{\hat{\Phi}}$ has a connected component with size more than $2k^4(1 + \xi) \log(n)$. In view of Lemma 48, the probability that Algorithm 1 outputs error due to the failure of the method Sample is at most $n^{-3\xi} = \varepsilon^3$. We conclude that the probability that the algorithm outputs error is bounded above by $\varepsilon/4 + \varepsilon^2 \leq \varepsilon/2$. Let $\mu_{\text{Glauber}}$ be the distribution that Algorithm 1 would output if there were no errors (that is, the distribution assuming that the method Sample always outputs from the appropriate distribution). Then $d_{TV}(\mu_{\text{alg}}, \mu_{\text{Glauber}})$ is the probability that an error occurs, which is at most $\varepsilon/2$. Let $\pi_{\text{Glauber}}$ be the distribution output by the $\rho$-uniform-block Glauber dynamics on $\mathcal{V}_m$ after $T$ steps. By Lemma 11 on the mixing time of the Glauber
dynamics, we have $d_{TV}(\pi_{\text{Glauber}}, \mu_{\Omega}) \leq \varepsilon/2$. As $\mu_{\text{Glauber}}$ comes from sampling an assignment $X_{\pi}$ from $\pi_{\text{Glauber}}$ and then completing $X_{\pi}$ to all $V$ by sampling from $\mu_{\Omega}(X_{\pi})$, we have $d_{TV}(\pi_{\text{Glauber}}, \mu_{\Omega}) \leq d_{TV}(\pi_{\text{Glauber}}, \mu_{\Omega}|_{\mathcal{V}_{n}}) \leq \varepsilon/2$. We find that $d_{TV}(\mu_{\text{alg}}, \mu_{\Omega}) \leq d_{TV}(\mu_{\text{alg}}, \mu_{\text{Glauber}}) + d_{TV}(\mu_{\text{Glauber}}, \mu_{\Omega}) \leq \varepsilon/2 + \varepsilon/2 = \varepsilon$ as we wanted. The running time of Algorithm 1 is now easily obtained by adding up the running times of the following subroutines. The good clauses and good variables are computed in time $O(n + km) = O(n)$, see Proposition 3. The marking $(\mathcal{V}_{n}, \mathcal{V}_{a}, \mathcal{V}_{c})$ is computed with probability at least $1 - \varepsilon/4$ in time $O(n \Delta k^2 \log(4/\varepsilon)) = O(n \log n)$, see Lemma 20. Recall that there are $T + 1 = O(n^0 \log(n/\varepsilon^2)) = O(n^0 \log n)$ calls to the method $\text{Sample}(\Phi', S)$, and each call takes time $O(|S| \log n) = O(n \log n)$ by Lemma 14. We conclude that the running time of Algorithm 1 is $O(n^{1+\theta} \log(n)^2)$. The result now follows by choosing $k_1 = k_0(\theta/2)$, so the running time for $k \geq k_1$ is $O(n^{1+\theta} \log(n)^2) = O(n^{1+\theta})$.

We have now proved that it is possible to (approximately) sample uniformly at random from the satisfying assignments of $\Phi = \Phi(k, n, |\alpha n|)$. At this point, standard techniques can be applied to obtain a randomised approximation scheme for counting the satisfying assignments of $\Phi$. These techniques are based on the self-reducibility of $k$-SAT [28]. The following remark shows how to obtain a randomised approximation scheme that runs in time $O(n^0(n/\varepsilon)^2)$ following [18, Chapter 7], where the authors base their counting algorithm on the simulated annealing method [39, 25, 30].

**Remark 49** (Approximate counting for random $k$-SAT formulas). Let $k_0(\theta)$ be the integer depending on $\theta \in (0, 1)$ obtained in Theorem 1. Let $k_1 = k_0(\theta/2)$, let $k \geq k_1$ be an integer, let $\xi$ be a positive integer and let $\alpha \leq 2^{0.039 - k}$ be a density. We apply Theorem 1 to obtain an algorithm to sample from the satisfying assignments of $\Phi = \Phi(k, n, |\alpha n|)$ within $n^{-k}$ total variation distance from the uniform distribution. This algorithm runs in time $O(n^{1+\theta/2})$ and succeeds w.h.p. over the choice of $\Phi$.

Let $\varepsilon \in (0, 1)$ with $\varepsilon \geq n^{-\xi}$. A modified version of the approximate counting algorithm of [18, Section 7], using $O(\varepsilon^{-2} n \log(n/\varepsilon))$ samples from the sampling algorithm above, approximates the number of satisfying assignments of the $k$-CNF formula $\Phi$ with multiplicative error $\varepsilon$, thus, achieving running time $O(n^{\theta/2}(n/\varepsilon)^2 \log(n/\varepsilon)) = O(n^0(n/\varepsilon)^2)$. Here we describe these minor modifications.

Let $\Omega_{\text{bad}}$ be the set of assignments $X: \mathcal{V} \rightarrow \{\text{F}, \text{T}\}$ that satisfy the bad clauses of $\Phi$. For $X \in \Omega_{\text{bad}}$, we define $F(X)$ to be the set of good clauses that are not satisfied by $X$. For $\kappa \in \mathbb{R}$, we define $w_{\kappa}(X) = \exp(-\kappa |F(X)|)$ and we define the partition function $Z(\kappa) = \sum_{X \in \Omega_{\text{bad}}} w_{\kappa}(X)$. The simulated annealing algorithm of [18, Section 7] uses $Z(\kappa)$ (with $\Omega^*$ from Definition 5 in place of $\Omega_{\text{bad}}$) to approximate the number of satisfying assignments of $\Phi$. We note that $Z(0) = |\Omega_{\text{bad}}|$, which can be computed in linear time in $n$ using the exact counting algorithm given in Proposition 29. Here one has to use the fact that the connected components of $G_{\Phi'}$ for the formula $\Phi' = (\mathcal{V}, \mathcal{C}_{\text{bad}})$ have size at most $2k^4 \log n$, see Lemma 55 from Appendix A and Lemma 25, and the fact that these connected component have tree-excess upper bounded as a function of $k$ (Lemma 24). Once one has performed these modifications, the algorithm given in [18, Section 7] applies without any difficulties.

Appendix A  Proof of Lemma 15

In this section we prove Lemma 15. Recall that this result is [21, Lemma 8.16] with a less restrictive bound on the density of the formula and a more restrictive definition of good variables/clauses, see Section 4 for details. Moreover, the obtained upper bound on the number of bad clauses in our version of [21, Lemma 8.16] is tighter. The original proof of Lemma 15 given in [21, Section 8] is split into a sequence of results on random formulas. Here we restate some of these results — only those whose statement needs to change as a consequence of our definition of good variables/clauses and the tighter upper bound. We also explain how these changes affect the proofs if any modifications are necessary.

Let us fix some notation first. The results stated in this section only hold for large enough $k$ unless we say otherwise. Moreover, across this section we fix a density $\alpha$ with $\alpha \leq \alpha_0 := 2^{(e^{2k}/2k)^2}$. We note that in [21] $\alpha$ is at most $2^{k/300}/k^3$. However, in the proofs of [21, Section 8], the only properties of $\alpha$ needed are that there is a real number $r_0 \in (0, 1/2)$ such that, for large enough $k$, $\alpha$ is bounded above by $2^{r_0 k}$, and that $\alpha \leq \Delta/k^3$, where $\Delta$ is the threshold for the definition of high-degree variables. In our setting we have $r_0 = 0.117841$ and $\Delta = [2^{(e^{2k}/2k)^2}]$, so this is not a problem. We need some definitions. For any set of variables $S \subseteq \mathcal{V}$ of $\Phi$, we denote by $\text{HD}(S)$ the set of high-degree variables in $S$. We denote $V_0 = \text{HD}(\mathcal{V})$.

**Corollary 50** ([21, Corollary 8.4]). W.h.p. over the choice of $\Phi$, for every set of variables $Y$ such that $2 \leq |Y| \leq n/2^k$, the number of clauses that contain at least 3 variables from $Y$ is at most $|Y|$.

**Proof.** This is a consequence of [21, Lemma 35] with $b = 3$ and $t = 2/(b - 1) = 1$. \hfill \Box

A $k$-CNF formula $\Phi = (\mathcal{V}, \mathcal{C})$ gives rise to a graph $H_\Phi$ with vertices in $\mathcal{V}$ that is defined as follows. Two variables $v_1$ and $v_2$ are adjacent in $H_\Phi$ if there is a clause $c \in \mathcal{C}$ with $v_1, v_2 \in \text{var}(c)$.

**Lemma 51** ([21, Lemma 8.8]). There is a positive integer $k_0$ such that for any integer $k \geq k_0$ and any density $\alpha$ with $\alpha \leq \alpha_0$, the following holds w.h.p. over the choice of $\Phi = \Phi(k, n, [\alpha n])$. Every connected set $U$ of variables in $H_\Phi$ with size at least $2k^4 \log n$ satisfies that $|\text{HD}(U)| \leq 1/2^{k^2}|U|$.

**Proof.** The proof is that of [21, Lemma 8.8], with the difference that $\delta_0 = 1/(2k^3)$ instead of $\delta_0 = 1/2^{1600}$, as the exact value of $\delta_0$ does not play a role in the proof as long as $1/\delta_0 = \text{poly}(k)$.

**Lemma 52** ([11, Lemma 2.4] and [21, Lemma 8.10]). Let $k \geq 3$ be an integer and let $\alpha$ be a positive real number with $\alpha \leq e^{k/2}/(2e^{2k^2})$. For any $\varepsilon \in [1/n, 1)$ (depending on $n$) such that $\varepsilon < e^{-3k}$ for all $n$, the following holds w.h.p. over the random choice of $\Phi = \Phi(k, n, [\alpha n])$. Let $Z$ be a set of clauses with size at most $\varepsilon n$ and let $c_1, \ldots, c_\ell \in \mathcal{C} \setminus Z$ be distinct clauses. For $s \in \{1, 2, \ldots, \ell\}$, let $N_s := \text{var}(Z) \cup \bigcup_{j \geq 2}^{\ell} \text{var}(c_j)$. If $|\text{var}(c_s) \cap N_s| \geq 3$ for all $s \in \{1, 2, \ldots, \ell\}$, then $\ell \leq cn$.

**Proof.** The proof is almost identical to the proof of [11, Lemma 2.4]. There are four differences. First, here, as it is also the case in [21, Lemma 44], $\varepsilon$ can depend on $n$. This will arise later in this proof. Second, the proof of [11, Lemma 2.4] is carried out for the condition $|\text{var}(c_s) \cap N_s| \geq \lambda$, where $\lambda$ is an integer with $\lambda > 4$. Here we set $\lambda = 3$ and impose stricter hypotheses on $\alpha$ and $\varepsilon$ to compensate for a smaller $\lambda$. Their (more relaxed) hypotheses on $\alpha$ and $\varepsilon$ are $\alpha \leq 2^k \log 2, \varepsilon \leq k^{-3}$ and $\varepsilon^3 \leq (2e)^{-4k}/e$. Third, we substitute the last inequality of [11, Equation 4], which is

$$\left[ \left( \frac{em/n}{\varepsilon} \right)^2 \exp(2k)^{2k\varepsilon^3} \right]^{\varepsilon n} \leq \left[ (2e)^{2k} e^{3k^2} \right]^{\varepsilon n}.$$

by the inequality

$$\left[ \left( \frac{em/n}{\varepsilon} \right)^2 \exp(2k)^{2k\varepsilon^3} \right]^{\varepsilon n} \leq \left[ (em/n)^2 \exp(2k)^{2k} \right]^{\varepsilon n} \leq \left[ \exp(3k - 1) \right]^{\varepsilon n},$$

(37)
where we used $\lambda = 3$ and $m/n \leq \alpha \leq e^{k/2}/(2e^2k^2)$. Now, as it is done in [21, Lemma 8.10], we distinguish two cases depending on $\varepsilon$. If $\varepsilon \geq 10(\log n)/n$, then using this in conjunction with $\varepsilon < e^{-3k}$, the right hand side of (37) is bounded by $e^{-\varepsilon n} \leq 1/n^{10} = o(1/n)$. If $1/n \leq \varepsilon < 10(\log n)/n$, then, for large enough $n$, the right hand size of (37) is bounded above by $\exp(3k - 1)\varepsilon = o(1)$. The last difference between the proofs is that our argument works for all $k \geq 3$, whereas the bound [11, Equation 4] only holds for large $k$.

The remaining results in this section do not need any changes in their original proofs, other than that every time Corollary 8.4, Lemma 8.8 and Lemmas 8.10-8.16 are invoked in [21, Section 8], we use the version given in this appendix instead. We note that the statements of these results are slightly different to their [21, Section 8] versions, and these changes are again due to the fact that we use $\lambda = 3$ instead of $\lambda = k/10$ in the definition of good variables/clauses.

**Corollary 53 ([21, Corollary 8.11]).** W.h.p. over the choice of $\Phi$, the following holds. Let $Z$ be a set of clauses with size at most $2n/2^{k/10}$ and let $c_1, \ldots, c_\ell \in C \setminus Z$ be distinct clauses. For $s \in \{1, 2, \ldots, \ell\}$, let $N_s := \text{var}(Z) \cup \bigcup_{j=1}^{s-1} \text{var}(c_j)$. If $|\text{var}(c_s) \cap N_s| \geq 3$ for all $s \in \{1, 2, \ldots, \ell\}$, then $\ell \leq |Z|$.

**Proof.** The proof given in [21, Corollary 8.11] also applies here.

**Lemma 54 ([21, Lemma 8.13]).** W.h.p. over the choice of $\Phi$, for any bad component $S$ of variables, we have $|S| \leq 2k|\text{HD}(S)|$.

**Proof.** The proof given in [21, Lemma 8.13] applies using our versions of [21, Corollary 8.4 and Corollary 8.11].

**Lemma 55 ([21, Lemma 8.14]).** W.h.p. over the choice of $\Phi$, every bad component $S$ has size at most $2k^4 \log n$.

**Proof.** The proof given in [21, Lemma 8.14] applies using our versions of [21, Lemma 8.8 and Lemma 8.13].

**Lemma 56 ([21, Lemma 8.15]).** W.h.p. over the choice of $\Phi$, for every connected set of $S$ variables with size at least $2k^4 \log n$, we have $|S \cap \mathcal{V}_{\text{bad}}| \leq |S|/k^2$.

**Proof.** The proof is analogous to that given in [21, Lemma 8.15]. The only differences are that we apply Lemma 51 instead of [21, Lemma 8.8], we apply Lemma 54 instead of [21, Lemma 8.13], and we have $\delta_0 = 1/(2k^3)$ instead of $\delta_0 = 1/21600$.

**Lemma 15 ([21, Lemma 8.16]).** There is an integer $k_0 \geq 3$ such that for any integer $k \geq k_0$ and any density $\alpha \leq \alpha_0 = 2^{(r_0-2\delta)k}/k^3$, the following holds w.h.p. over the choice of the random $k$-CNF formula $\Phi = \Phi(k, n, |\alpha n|)$. For every connected set of clauses $Y$ in $G_\Phi$ such that $|\text{var}(Y)| \geq 2k^4 \log n$, we have $|Y \cap C_{\text{bad}}| \leq |Y|/k$.

**Proof.** The same proof applies using our versions of [21, Corollary 8.4 and Lemma 8.15].
Appendix B  Proof of Lemma 9

In this section we collect the results from [8] that one needs to combine to obtain Lemma 9 on the mixing time of the \( \rho \)-uniform-block Glauber dynamics.

**Definition 57.** Let \( \mu \) be a distribution supported on \( \Omega \subseteq [q]^V \). Let \( f : \Omega \to \mathbb{R}_{\geq 0} \). We denote the entropy of \( f \) by \( \text{Ent}_\mu(f) \), that is, \( \text{Ent}_\mu(f) = \mathbb{E}_\mu(f \log f) - \mathbb{E}_\mu(f) \log(\mathbb{E}_\mu(f)) \) when \( \mathbb{E}_\mu(f) > 0 \), and \( \text{Ent}_\mu(f) = 0 \) when \( \mathbb{E}_\mu(f) = 0 \). For \( S \subseteq V \), we denote \( \text{Ent}^S_\mu(f) = \mathbb{E}_{\tau \sim \mu|V\setminus S} \text{Ent}_\mu(f|\tau) \), where \( \text{Ent}_\mu(f|\tau) \) is the entropy of \( f \) conditioning to the event that the assignment drawn from \( \mu \) agrees with \( \tau \) in \( V \setminus S \).

Let \( \rho \in \{1,2,\ldots,n\} \). We say that \( \mu \) satisfies the \( \rho \)-uniform block factorisation of entropy (with constant \( C_\rho \)) if for all \( f : \Omega \to \mathbb{R}_{\geq 0} \) we have

\[
\frac{\rho}{n} \text{Ent}_\mu(f) \leq C_\rho \frac{1}{n} \sum_{S \in \binom{V}{\rho}} \text{Ent}^S_\mu(f).
\]

One of the main results of [8] is showing that \( \mu \) satisfies the \( \rho \)-uniform block factorisation of entropy when the distribution \( \mu \) is \( \eta \)-spectrally independent and \( b \)-marginally bounded. In the proof of [5, Corollary 19] the authors observe that the proof of Lemma 58 also holds when \( \eta \) depends on \( n \) and, in particular, in the case \( \eta = \varepsilon \log n \).

**Lemma 58 ([8, Lemma 2.4]).** The following holds for any reals \( b, \eta > 0 \), any \( \kappa \in (0,1) \) and any integer \( n \) with \( n \geq \frac{3}{2}(4\eta/b^2 + 1) \).

Let \( q \geq 2 \) be an integer, let \( V \) be a set of size \( n \) and let \( \mu \) be a distribution over \( [q]^V \). If \( \mu \) is \( b \)-marginally bounded and \( \eta \)-spectrally independent, then \( \mu \) satisfies the \( \lceil \kappa n \rceil \)-uniform block factorisation of entropy with constant \( C = (2/\kappa)^{4\eta/b^2 + 1} \).

It turns out that one can bound the mixing time of the \( \rho \)-uniform-block Glauber dynamics when the target distribution \( \mu \) satisfies the \( \rho \)-uniform block factorisation of entropy.

**Lemma 59** (See, e.g., [8, Lemma 2.6 and Fact 3.5(4)] or [5, Lemma 17]). Let \( q \geq 2 \), \( \rho \geq 1 \) be integers and \( V \) be a set of size \( n \geq \rho + 1 \). Let \( \mu \) be a distribution supported on \( \Omega \subseteq [q]^V \) that satisfies the \( \rho \)-uniform-block factorisation of entropy with multiplier \( C_\rho \). Then, for any \( \varepsilon > 0 \), the mixing time of the \( \rho \)-uniform-block Glauber dynamics on \( \mu \) satisfies, for \( \mu_{\min} = \min_{\Lambda \in \Omega} \mu(\Lambda) \),

\[
T_{mix}(\varepsilon) \leq \left[ C_\rho \frac{n}{\rho} \left( \log \log \frac{1}{\mu_{\min}} + \log \frac{1}{2\varepsilon^2} \right) \right].
\]

**Proof of Lemma 9.** The proof of Lemma 9 follows directly from combining Lemmas 58 and 59. \( \Box \)
Appendix C  Notation and definitions reference

Here we gather the notation and definitions that are used globally in our work. If some notation is not here, then it is only used in one section of our work (and it is defined in that section).

C.1 Table of notation

| Notation | Description | Reference |
|----------|-------------|-----------|
| $\Phi(k, n, m)$ | A random $k$-CNF formula with $n$ variables and $m$ clauses. | Section 1 |
| $\alpha$ | The density of the formula $\Phi$, so $\alpha = m/n$. | Section 1 |
| $\mathcal{V}$ | The set of variables of $\Phi$. | Section 1 |
| $\mathcal{C}$ | The set of clauses of $\Phi$. | Section 1 |
| w.h.p. | Stands for “with high probability”. | Section 1 |
| $d_{TV}$ | The total variation distance between two distributions. | Section 1 |
| $r$ | The constant $r = 0.1178$ determines the density threshold $\alpha \leq 2^{r^k}$ in Lemma 13. | |
| $\xi$ | Our sampling algorithm has error at most $n^{-\xi}$. | Theorem 1 |
| $r_0, \delta$ | $r_0 = 0.117841$ and $\delta = 0.00001$. | Definition 2 |
| $\Delta$ | The high-degree threshold, set to $[2^{(r_0-2\delta)k}]$. | Definition 2 |
| $\alpha_0$ | The density threshold for the existence of an $r_0$-marking, set to $2^{(r_0-2\delta)k}/k^3$. | Definition 2 |
| $\text{var}(c)$ | The set of variables in a clause $c$. | Section 2.1 |
| $\text{var}(S)$ | The set of variables $\bigcup_{c \in S} \text{var}(c)$. | Section 2.1 |
| $\mathcal{C}_{\text{good}}, \mathcal{C}_{\text{bad}}$ | Good and bad clauses, a partition of $\mathcal{C}$. | Section 4 |
| $\mathcal{V}_{\text{good}}, \mathcal{V}_{\text{bad}}$ | Good and bad variables, a partition of $\mathcal{V}$. | Section 4 |
| $\mathcal{V}_{\text{m}}, \mathcal{V}_{\text{a}}, \mathcal{V}_{\text{c}}$ | The sets of marked, auxiliary and control variables. | Definition 4 |
| $\Omega^*$ | The set of all assignments $\mathcal{V} \rightarrow \{F, T\}$ | Definition 5 |
| $\Omega$ | The set of satisfying assignments of $\Phi$. | Definition 5 |
| $\mu_A$ | The uniform distribution over $A \subseteq \Omega^*$. | Definition 5 |
| $\Phi^\Lambda$ | The formula $\Phi$ simplified under $\Lambda$. | Definition 5 |
| $\mathcal{V}^\Lambda, \mathcal{C}^\Lambda$ | The variables and clauses of $\Phi^\Lambda$. | Definition 5 |
| $\Omega^\Lambda$ | The set of satisfying assignments of $\Phi^\Lambda$. | Definition 5 |
| $\mu_{\mathcal{V}}$ | The marginal distribution of $\mu$ on $\mathcal{V}$. | Definition 7 |
| $T_{\text{mix}}(\rho, \varepsilon)$ | The mixing time of the $\rho$-uniform-block Glauber dynamics. | Section 2.2.1 |
| $I^\Lambda(u \rightarrow v)$ | The influence of $u$ on $v$ (under $\Lambda$). | Section 2.2.1, (1) |
| $G_\Phi$ | The dependency graph of $\mathcal{C}$. | Definition 12 |
| $\Phi_{\text{good}}$ | The subformula of $\Phi$ with all good variables and good clauses. | Definition 18 |
| $\Phi_{\text{bad}}$ | The subformula of $\Phi$ with all bad variables and bad clauses. | Definition 18 |
C.2 Table of definitions

| Name                     | Reference                  |
|--------------------------|----------------------------|
| high-degree              | Definition 2, page 3       |
| $r$-distributed          | Definition 4, page 4       |
| $r$-marking              | Definition 4, page 4       |
| $\varepsilon$-uniform    | Definition 8, page 5       |
| $b$-marginally bounded   | Section 2.2.1, page 6      |
| $\eta$-spectrally independent | Section 2.2.1, page 6   |
