Experimental section

Materials

Graphite powder, KMnO₄, H₂SO₄ and HNO₃, poly(vinylidene fluoride) (PVDF), N-methyl-2-pyrrolidinone (NMP) were purchased from Wako Pure Chemical Industry. Zn(NO₃)₂·6H₂O, 2-methylimidazole (2-MeIM), and phytic acid (PA) solution 50 % (w/w) in H₂O were purchased from Sigma-Aldrich. All chemicals were used as received without further purification.

Preparation of graphene oxide (GO)

In brief, graphite powder was added to a solution of concentrated HNO₃ and H₂SO₄ (1:2 v/v) and maintained at 80 °C for 5 h. The mixture was then allowed to cool to room temperature, deionized (DI) water was added, and the mixture allowed to stand overnight. The reaction vessel was then placed in an ice bath, KMnO₄ was slowly added. Subsequently, the mixture was allowed to stand with stirring for 2 h. After dilution with DI water, 30% H₂O₂ was added to the mixture, and the colour of the mixture changed to brilliant yellow, accompanied by bubbling. The mixture was then filtered and the solid washed with aqueous HCl solution (1:10 v/v), DI, and ethanol. Finally, GO was obtained by freeze drying.

Preparation of ZIF-8/GO

Briefly, Zn(NO₃)₂·6H₂O (0.366 g) and 2-MeIM (0.811 g) were dissolved in methanol (12 mL and 20 mL, resp.). The methanolic Zn(NO₃)₂ solution (12 mL) was then added to the 2-MeIM solution to obtain a clear solution. GO solution (1 mg mL⁻¹ in water, 8 mL) was immediately added to the Zn(NO₃)₂/2-MeIM mixed solution. After stirring for 20 min, the gray precipitate was collected by centrifugation (8000 rpm for 5 min) and was washed three times with methanol. Zeolitic imidazolate framework-8 ZIF-8/GO was obtained after freeze-drying.
Preparation of NC/rGO

ZIF-8/GO nanosheets were converted to NC/rGO nanosheets by carbonization at 950 °C for 2 h under a N₂ atmosphere. The ramping rate was 1 °C min⁻¹ in the first stage (below 350 °C) and increased to 5 °C min⁻¹ in the second stage (350 to 950 °C). For comparison, ZIF-8 was obtained without adding the GO solution and employed as the precursor to NC by direct carbonization with the same process.

Preparation of porous NPC/rGO

NPC/rGO nanosheets were prepared by post-activation with PA. In a typical activation process, NC/rGO (30.0 mg) were dispersed in ethanol (1.5 mL) containing PA solution (170 μL). The suspension was then transferred to a quartz boat and dried at 60 °C. Subsequently, the quartz boat was placed in a quartz tube and heated under a N₂ atmosphere. The temperature was increased to 350 °C then 550 °C at a ramp rate of 5 °C min⁻¹. Each stage was held for 0.5 h. Temperature was then increased to 1000 °C and held for another 2 h.

Characterization.

Crystal identity of the samples was characterized by using powder X-ray diffraction (XRD, Ultima Rint 2000 X-ray diffractometer, RIGAKU, Japan) measurements using Cu Kα radiation (40 kV, 40 mA, 2° min⁻¹ scan rate). Morphologies of the samples were observed by field-emission scanning electron microscopy (FESEM, HITACHI SU8000). Mesoporous structure of the samples was confirmed by transmission electron microscopy (TEM, JEOL JEM-2100). N₂ adsorption-desorption isotherms were obtained by using a Belsorp-max (BEL, Japan) instrument where the specific surface areas and pore size distributions were analyzed by the Brunauer-Emmett-Teller (BET) method and Barrett-Joyner-Halenda (BJH) models, respectively. X-ray photoelectron spectroscopy (XPS, Axis Ultra, Kratos Analytical Ltd) was used to investigate the chemical state of phosphorus and nitrogen in the samples. The Zeta potential measurements were done in aqueous solutions of the samples in function of pH values ranging from 3 to 11 by Zeta sizer Nano-ZS90 (Malvern,
United Kingdom).

**Electrochemical analyses**

The electrochemical measurements were performed on CHI 660E electrochemical workstation in a three-electrode system with 1 M NaCl aqueous electrolyte. A platinum (Pt) wire and Hg/HgO were selected as the counter electrode and reference electrode, respectively. Cyclic voltammetry (CV) and gravimetric charge-discharge (GCD) measurements were carried out in the potential range of -0.5 to 0.5 V.

The specific capacitances \( (C, \text{F g}^{-1}) \) were calculated from the CV curves by using the following equation:

\[
C = \int i dV / 2\Delta V m v
\]

(1)

where \( i \) is the discharge current density (A), \( m \) is the mass of active materials (g), \( \Delta V \) is the voltage window (V), \( v \) is the scan rate (V s\(^{-1}\)).

**Desalination analysis**

Each individual CDI electrode was fabricated by depositing a mixture of the sample, Super-P and PVDF binder with a weight ratio of 8:1:1. The mixture was pressed onto graphite paper \((2.5 \times 2.5 \text{ cm}^2)\) and dried under reduced pressure at 60 °C for 12 h.

CDI tests were conducted using a batch-mode with continuous recycling system, which consists of a pair of anion- and cation-exchange membranes, a peristaltic pump, a power source, and a tank. The real-time saline concentration variation was monitored and measured by using an ion conductivity meter. The volume of the saline solution was fixed at 30 mL, the flow rate was 30 mL min\(^{-1}\), and the operating voltage was 1.2 V.

The salt adsorption capacity \( (\Gamma, \text{mg g}^{-1}) \) and mean salt adsorption rate \( (MSAR, \text{mg g}^{-1} \text{min}^{-1}) \) at \( t \) min were calculated as follows:

\[
\Gamma = (C_0 - C_t) \times V / m
\]

(2)

\[
MSAR = \Gamma / t
\]

(3)
where \( C_0 \) and \( C_t \) represent the concentrations of NaCl at the initial stage and \( t \) min, respectively (mg L\(^{-1}\)); \( V \) is the volume of the NaCl solution (L); and \( m \) represents the total mass of the electrode materials (g).
