(Dated: May 10, 2014)

We study the relation between the eigenfrequencies of the Bogoliubov excitations of Bose-Einstein condensates, and the eigenvalues of the Jacobian stability matrix in a variational approach which maps the Gross-Pitaevskii equation to a system of equations of motion for the variational parameters. We do this for Bose-Einstein condensates with attractive contact interaction in an external trap, and for a simple model of a self-trapped Bose-Einstein condensate with attractive $1/r$ interaction. The stationary solutions of the Gross-Pitaevskii equation and Bogoliubov excitations are calculated using a finite-difference scheme. The Bogoliubov spectra of the ground and excited state of the self-trapped monopolar condensate exhibits a Rydberg-like structure, which can be explained by means of a quantum defect theory. On the variational side, we treat the problem using an ansatz of time-dependent coupled Gaussians combined with spherical harmonics. We first apply this ansatz to a condensate in an external trap without long-range interaction, and calculate the excitation spectrum with the help of the time-dependent variational principle. Comparing with the full-numerical results, we find a good agreement for the eigenfrequencies of the lowest excitation modes with arbitrary angular momenta. The variational method is then applied to calculate the excitations of the self-trapped monopolar condensates, and the eigenfrequencies of the excitation modes are compared.

I. INTRODUCTION

In the quantum mechanical description of the ground states of Bose-Einstein condensates in the framework of the Gross-Pitaevskii equation, the frequencies of elementary excitations of the condensates are obtained by solving the Bogoliubov-de Gennes equations. In an alternative description, a variational approach with coupled Gaussian functions has recently been proposed by Rau et al. [1, 2] which maps the Gross-Pitaevskii equation to a dynamical system for the variational parameters that can be analyzed using the familiar tools of classical nonlinear dynamics. Ground states correspond to the fixed points of the dynamical system, and their stability properties follow from the eigenvalues of the Jacobian at the fixed points. In this paper we shall investigate the question whether or not there is a relation between the eigenvalues of the Jacobian and the eigenfrequencies of the quantum mechanical Bogoliubov excitations, and if so, to what extent the eigenvalues of the Jacobian can reproduce the frequencies of these excitations.

The realization of a Bose-Einstein condensate (BEC) with $^{52}$Cr atoms [3] marked the beginning of experimental investigations of BECs with long-range interactions. The anisotropic dipole-dipole interaction caused by the large magnetic moment of the $^{52}$Cr atoms influences the properties of new phenomena, such as a roton-maxon spectrum [4], structured ground states [5, 6], and angular collapse [7]. Recently a condensate of $^{164}$Dy atoms with an even larger magnetic moment was created [8, 9], and BECs of other lanthanides with a strong dipole-dipole interaction should be possible [10].

A model of a BEC with a different long-range interaction was proposed by O’Dell et al. [12]. In contrast to the dipolar interaction, this interaction is monopolar, i.e., “gravity-like” with an attractive $1/r$ potential. Although it will be difficult to realize this model experimentally, BECs with monopolar long-range interaction are worth investigating in their own right, since they exhibit the phenomenon of self-trapping [12], i.e., the existence of a stable condensate without an additional external trap. Furthermore, the isotropic character of the interaction renders numerical investigations easier than in the anisotropic case, and therefore BECs with monopolar interaction can serve as model systems for the treatment of condensates with long-range interactions to test new approaches and techniques.

The stationary states of self-trapped monopolar condensates have been calculated in the Thomas-Fermi regime and with the variational ansatz of a single Gaussian [12], full-numerically [13], and with an ansatz of coupled Gaussians [1, 2]. Several aspects of the excitation spectrum have also been investigated [2, 14, 15], but a comprehensive study is still lacking. In this paper we will solve the Bogoliubov-de Gennes equations and reveal a Rydberg-like structure in the numerically exact Bogoliubov spectra, similar to the spectra of alkali metals.

The full-numerical calculations are very accurate, if – depending on the method – grid size, number of basis functions, etc., are chosen carefully, but may become computationally very expensive. As an alternative we pursue a variational ansatz with coupled Gaussian functions. Single Gaussians have been used in the literature to obtain qualitative results for BECs (e.g. in [12, 16]). The ansatz can be extended to time-dependent coupled...
interaction and long-range monopolar interaction reads for the self-trapped condensate with short-range contact interactions. Our variational ansatz is based on a combination of coupled Gaussians with spherical harmonics. Several extensions of a Gaussian ansatz have been considered in the literature, e.g., Gaussians with Hermite or Laguerre polynomials or sines and cosines. But these methods allow for no systematic improvement of the ansatz, which is the case for the variational method we present in this paper.

Our variational ansatz is based on a combination of coupled Gaussians with spherical harmonics, and can describe excitations with arbitrary angular momenta in radially symmetric systems. The power of the method will be demonstrated by applying it to BECs without and with monopolar long-range interaction.

The method is applied to BECs without and with the monopolar long-range interaction. In Sec. IV we draw conclusions and give an outlook on future work.

II. FULL-NUMERICAL TREATMENT OF THE SELF-TRAPPED MONOPOLAR CONDENSATE

The time-dependent Gross-Pitaevskii equation (GPE)

\[ i \frac{\partial \psi}{\partial t}(r,t) = \left[ -\Delta + 8\pi a |\psi(r,t)|^2 - 2 \int d^3r' \frac{|\psi(r',t)|^2}{|r-r'|} \right] \psi(r,t), \tag{1} \]

where \( a \) denotes the s-wave scattering length. Since we will concentrate on the case of self-trapping, the external potential has been omitted. All variables in Eq. (1) are given in the natural units introduced in [13]. Lengths are measured in units of the “Bohr radius” \( a_B = \hbar^2/mu \), energies in units of the “Rydberg energy” \( E_R = u/2a_B \), and time in units of \( t_B = \hbar/E_R \). The quantity \( u \) is the coupling constant of the monopolar interaction defined in [12] and depends on the intensity and wave number of the laser, and the polarizability of the atoms.

Eq. (1) represents the GPE for the fictitious one-boson problem. One can make use of the scaling property of [13] to scale all quantities to an \( N \)-boson system:

\[ (r, a, t, \psi) \rightarrow (N r, N^2 a, N^2 t, N^{-3/2} \psi). \tag{2} \]

The scaled dimensionless units are used throughout this work and in all figures whenever considering monopolar condensates. In these units, the only remaining parameters are the scattering length \( a \) [13]. The stationary GPE can be obtained by substituting

\[ \psi(r, t) = \psi(r) \exp(-i\mu t), \]

with the chemical potential \( \mu \), in the time-dependent GPE (1), which leads to

\[ \mu \psi(r) = \left[ -\Delta + 8\pi a |\psi(r)|^2 - 2 \int d^3r' \frac{|\psi(r')|^2}{|r-r'|} \right] \psi(r). \tag{3} \]

A. Calculation of stationary solutions

For a numerical treatment of the stationary GPE, it is convenient to convert the integro-differential equation into two coupled differential equations. This can be achieved by defining the mean-field potential

\[ \phi(r) = -2 \int d^3r'' \frac{|\psi(r'')|^2}{|r-r''|}. \tag{4} \]

Since we search for radially symmetric stationary solutions we assume the wave function and the mean-field potential to depend only on the radial coordinate: \( \psi(r) = \psi(r) \) and \( \phi(r) = \phi(r) \). Letting the Laplacian in spherical coordinates act on Eq. (4) one obtains the two one-dimensional, nonlinear coupled differential equations

\[ \left( -\frac{d^2}{dr^2} - \frac{2}{r} \frac{d}{dr} + 8\pi a |\psi(r)|^2 + \phi(r) \right) \psi(r) = \mu \psi(r), \tag{5a} \]

\[ \left( \frac{d^2}{dr^2} + \frac{2}{r} \frac{d}{dr} \right) \phi(r) - 8\pi |\psi(r)|^2 = 0. \tag{5b} \]

The system of Eqs. (5) can be solved numerically in different ways. Since it is a one-dimensional problem, one can integrate the equations using a Runge-Kutta algorithm from \( r = 0 \) to a sufficiently large value \( r_{\text{max}} \) with appropriately chosen initial conditions for \( \psi(0), \psi'(0), \phi(0) \) and \( \phi'(0) \). Their values must be varied until the wave function converges towards zero at \( r = r_{\text{max}} \). With this method the ground and excited state can be calculated efficiently. However, to obtain a normalized solution \( \psi(r) \) the wave function, scattering length, and mean field energy must be rescaled. Thus, it is difficult to obtain a solution for a given fixed value of the scattering length. Additionally, it is not easy to calculate the Bogoliubov spectrum of the system with this method, since the solutions of the Bogoliubov-de Gennes (BDG) equations have large extensions, and a very big value of \( r_{\text{max}} \) has to be chosen. For example, to calculate 20 eigenvalues for an angular momentum of \( l = 6 \),
\[ r_{\text{max}} \text{ needs to be larger than 1000. In this case, machine precision in the Runge-Kutta method is not sufficient to obtain converged solutions, leaving this method useless for higher modes.} \]

Another method is the imaginary time evolution (replacement \( t \to t = i\tau \) in Eq. (1)) of an initial wave function on a grid. As time evolves the wave function converges to the ground state. This method is useful to find the ground state or a metastable state of a system. However, a collectively excited state, as we consider below, cannot be obtained by imaginary time evolution.

To avoid these disadvantages, we use the finite-difference method to solve the stationary GPE (5): Wave functions and the mean-field potential are discretized on a grid and all derivatives are replaced by their finite-difference approximation. To arrive at a closed system of algebraic equations which can be solved by a nonlinear root search one needs appropriate boundary conditions: \( \psi'(0) = 0 \) and \( \psi'(\infty) = 0 \), to ensure that the functions are differentiable at the origin, and \( \psi(\max) = 0 \) to obtain a normalizable wave function. The fourth boundary condition can be obtained by looking at the asymptotic behavior of the mean-field potential. Approximating \( 1/|r-r'| \approx 1/r \) for \( r \gg r' \) and assuming a normal wave function \( \psi \), one obtains from Eq. (4) \( \phi(r) \approx -2/r \). The fourth boundary condition is therefore set to be \( \phi(\max) = -2/\max \).

We perform the nonlinear root search using the Powell hybrid method. In addition to the equations originating from the finite-difference scheme, the normalization condition has to be included, as well as the chemical potential as a parameter to be determined by the root search.

### B. Bogoliubov-de Gennes equations

The stability and elementary excitations of a self-trapped monopolar condensate have already been analyzed in the literature: the lowest monopole and quadrupole oscillation analytically and numerically \([14]\), the first monopole modes \([22]\), and the lowest monopole and quadrupole modes by means of a variational ansatz with coupled Gaussians \([2]\). However, to the best of our knowledge, a calculation of the Bogoliubov spectrum for arbitrary angular momenta and higher excitations does not yet exist.

To derive the BDG equations, one starts from the usual ansatz for a perturbation of a stationary state

\[
\psi(r, t) = \left[ \psi_0(r) + \lambda \left( u(r) e^{-i\omega t} + v^*(r) e^{i\omega t} \right) \right] e^{-i\mu t},
\]

where \( \omega \) is the frequency and \( \lambda \) the amplitude of the perturbation \((|\lambda| \ll 1)\), and \( \mu \) is the chemical potential of the stationary solution \( \psi_0 \) with corresponding mean-field potential \( \phi_0 \). Eq. (6) is inserted into the time-dependent GPE (1), terms of second order in \( \lambda \) are neglected, and collecting terms evolving in time with \( \exp(-i\omega t) \) and \( \exp(i\omega t) \) yields the BDG equations

\[
\begin{align*}
\omega u(r) &= \left[ -\Delta - \mu + 16\pi a |\psi_0(r)|^2 + \phi_0(r) \right] u(r) + 8\pi a (\psi_0(r))^2 v(r) + \psi_0(r) f(r), \\
-\omega v(r) &= \left[ -\Delta - \mu + 16\pi a |\psi_0(r)|^2 + \phi_0(r) \right] v(r) + 8\pi a (\psi_0^*(r))^2 u(r) + \psi_0^*(r) f(r),
\end{align*}
\]

with the auxiliary field (similar to the mean-field potential)

\[ f(r) = -2 \int \frac{d^3r'}{4\pi^3} \frac{\psi_0^*(r')u(r') + \psi_0(r')v(r')}{|r-r'|}. \]

The ansatz of Eq. (6) possesses a symmetry: the exchange of \( u(r) \leftrightarrow v^*(r) \) and \( \omega \leftrightarrow -\omega \) leaves the ansatz invariant. Thus for each solution \((u, v) \) and \( \omega \) of Eqs. (7), \((v^*, u^*) \) with \( -\omega \) is another solution and both solutions represent the same physical motion. For that reason, only solutions with \( \text{Re} \omega \geq 0 \) need to be considered. There are two solutions of Eqs. (7) which deserve special attention. If \( \psi_0 \) is assumed to be real, then \( u(r) = -v(r) = \psi_0(r) \) is a solution of Eqs. (7) with the frequency \( \omega = 0 \). This represents the well-known gauge transformation of the condensate wave function \( \psi(r) \to \psi(r) \exp(i\phi) \) with a real phase \( \phi \). This gauge mode does not describe a physical motion of the condensate, and since it is always part of the Bogoliubov spectrum, we will not discuss it when presenting the results.

Furthermore, there always exist solutions of the BDG equations with frequencies identical to the trapping frequencies \([21]\). These modes represent the center-of-mass oscillations of the condensate along the three space directions with angular momentum \( l = 1 \). In the case of the self-trapped monopolar condensate, there are no external traps and therefore the frequencies are \( \omega = 0 \), which corresponds to a constant displacement of the condensate.

Since the wave function \( \psi_0 \) and the mean-field potential \( \phi_0 \) are radially symmetric, we can separate the solutions \( u \) and \( v \) by means of spherical harmonics

\[
\begin{align*}
u_{nlm}(r) &= Y_{lm}(\theta, \phi)u_{nl}(r), \\
v_{nlm}(r) &= Y_{lm}(\theta, \phi)v_{nl}(r),
\end{align*}
\]
with the radial (excitation) quantum number \( n \) and the usual angular momentum quantum numbers \( l, m \). Using the multipole expansion of the integration kernel \( 1/|r - r'| \) (see, e.g., [26] and Eq. (A.29)), we can also express the auxiliary field \( f \) in the form \( f_{nlm}(r) = Y_{nlm}(\theta, \phi) f_{nl}(r) \) with \( \psi_0 \) and \( \phi_0 \) are assumed to be real from now on)

\[
f_{nl}(r) = \frac{-8\pi}{2l + 1} \int_0^\infty dr' (r')^2 \frac{r'}{r} \psi_0(r') [u_{nl}(r') + v_{nl}(r')],
\]

(10)

\[
\omega_{nl}u_{nl}(r) = \left[ -\frac{d^2}{dr^2} - \frac{2}{r} \frac{d}{dr} + \frac{l(l + 1)}{r^2} - \mu - 16\pi a^2 \phi_0(r) \right] u_{nl}(r) + 8\pi a^2 \psi_0^2(r) v_{nl}(r) + \psi_0(r) f_{nl}(r),
\]

(11a)

\[
-\omega_{nl}v_{nl}(r) = \left[ -\frac{d^2}{dr^2} - \frac{2}{r} \frac{d}{dr} + \frac{l(l + 1)}{r^2} - \mu - 16\pi a^2 \phi_0(r) \right] v_{nl}(r) + 8\pi a^2 \psi_0^2(r) u_{nl}(r) + \psi_0(r) f_{nl}(r).
\]

(11b)

We solve Eqs. (11) using the finite-difference method. After choosing a grid, approximating the derivatives by finite differences and replacing the integral in the auxiliary field \( f \) by an appropriate integration rule (we use the trapezoidal rule), Eqs. (11) turn into a matrix eigenvalue problem

\[
M \begin{pmatrix} u \\ v \end{pmatrix} = \omega \begin{pmatrix} u \\ v \end{pmatrix}.
\]

(12)

The eigenvalues of the matrix \( M \) can then be found by numerical diagonalization.

In actual calculations we found it advantageous to choose a non-equidistant grid, since the solutions \( u \) and \( v \) can be highly oscillatory near the origin, and at the same time extend to large values of \( r \). We use partially equidistant grids, i.e., an equidistant grid with step size \( \Delta r_1 \) in the interval \([0, r_1]\), another equidistant grid with a different \( \Delta r_2 \) in the interval \([r_1, r_2]\), etc.

C. Results

Since the properties of the stationary solution have been discussed in detail in the literature [13, 15, 22], we only give a brief review. Our results coincide with those obtained using the outward integration method, and thus for the stationary states both methods can be considered equally applicable. In Fig. 1 we plot the mean-field energy \( E_{mf} \) and chemical potential \( \mu \) of the ground and excited state of a self-trapped monopolar condensate as functions of the scattering length \( a \). For a scattering length lower than the critical value of \( a_{crit} \approx -1.025 \) no stationary solution exists. At \( a = a_{crit} \) the two solutions emerge in a tangent bifurcation. For the ground state, both \( E_{mf} \) and \( \mu \) stay negative in the range of the scattering length considered. These quantities diverge for the excited state in the limit \( a \rightarrow 0 \).

![Figure 1](https://via.placeholder.com/150)

Figure 1. (Color online) Mean-field energy \( E_{mf} \) and chemical potential \( \mu \) of the ground and excited state of a self-trapped monopolar condensate as functions of the scattering length \( a \). For a scattering length lower than the critical value of \( a_{crit} \approx -1.025 \) no stationary solution exists. At \( a = a_{crit} \) the two solutions emerge in a tangent bifurcation. For the ground state, both \( E_{mf} \) and \( \mu \) stay negative in the range of the scattering length considered. These quantities diverge for the excited state in the limit \( a \rightarrow 0 \).

Using the method described in Sec. IIIB we have calculated the Bogoliubov spectrum of the ground state. For the angular momenta from \( l = 0 \) to 3, Fig. 2 shows the frequencies of the Bogoliubov excitations as a function of the scattering length \( a \). The ground state is stable, since its spectrum contains only real frequencies. It can be seen that as the scattering length is decreased towards
its critical value the frequency of the lowest mode with \( l = 0 \) at first slightly increases but then goes to zero at \( a \to a_{\text{crit}} \), where the state vanishes. This mode is responsible for the collapse of the condensate. The lowest \( l = 1 \) mode has the frequency \( \omega = 0 \) and corresponds to the displacement of the center-of-mass of the condensate. This frequency remains constantly \( \omega = 0 \) as the scattering length is varied, and, as already mentioned, corresponds to the (vanishing) trapping frequency.

The results for the excited state are presented in Fig. 3. All frequencies merge with those of the ground state modes at the critical scattering length. There exists one imaginary frequency for the angular momentum \( l = 0 \). Therefore the excited state is unstable with respect to this excitation, which leads to a collapse with \( l = 0 \) symmetry. As for the ground state the lowest mode with \( l = 1 \) represents the displacement of the condensate and is constantly \( \omega = 0 \).

In Fig. 4 the Bogoliubov functions \( u_0(r) \) and \( v_0(r) \) are shown for the angular momentum \( l = 0 \). The lowest functions with \( n = 1 \) and \( n = 2 \) are concentrated near the origin and have the same extension as the wave function of the stationary solution (see Fig. 5). For the higher modes, the functions \( u \) extend further out, which is a consequence of the missing external trapping potential.

D. Quantum defect analysis of the Bogoliubov spectrum

To prove that for given scattering length the frequencies of the Bogoliubov excitations converge to a limiting frequency we determined the 20 lowest modes for the angular momenta \( l = 0 \) to 6. As an example, Fig. 5...
the frequencies to a common limit, independent of
ubov spectrum of the ground state. The convergence of
shows, for the scattering length \( a = -0.4 \), the Bogoli-
quotes the term containing \( \psi_0 \) can be neglected in (11), and \( \phi_0 \)
can be approximated by \(-2/r\). This leads to the asymp-
totic form of the BDG equations

\[
\begin{align}
\omega_{nl} u_{nl}(r) &= \left[ -\frac{d^2}{dr^2} - \frac{2}{r} \frac{d}{dr} + \frac{l(l+1)}{r^2} - \mu - \frac{2}{r} \right] u_{nl}(r),
\end{align}
\]

(13a)

\[
\begin{align}
-\omega_{nl} v_{nl}(r) &= \left[ -\frac{d^2}{dr^2} - \frac{2}{r} \frac{d}{dr} + \frac{l(l+1)}{r^2} - \mu - \frac{2}{r} \right] v_{nl}(r).
\end{align}
\]

(13b)

Obviously in this limit \( u \) and \( v \) obey the same equa-
tion, namely the Schrödinger equation of the Coulomb
problem, except for the opposite sign of the eigenvalues.
Therefore asymptotically only one equation of (13) needs
to be considered (which will be the one for \( u \)). The scat-
tering length enters into Eqs. (13) only indirectly via
\( \mu = \mu(a) \).

The approximations made are only valid, if the func-
tion values of \( u \) and \( v \) are small for \( r < r_c \). Especially
for lower angular momenta this is not the case. In the
physics of alkali metals a similar problem occurs: The
valence electron far away from the nucleus “feels” an at-
tractive \(-1/r\) potential, which results from the shielding
of the core electrons. Close to the nucleus, the core elec-
trons and the true nuclear potential has to be consid-
ered. A similar situation happens here, cf. Fig. 6 To
account for the deviation of the potential from the pure
Coulomb potential at smaller values of the radial coordi-
rate we can also introduce a quantum defect in the formula
for the Rydberg series eigenvalues (see, e.g., [26]),

\[
\omega_{nl} = -\mu - \frac{1}{(n+l+1-\delta_l)^2},
\]

(14)

where the quantum defects \( \delta_l \) depend on the angular
momentum. The negative chemical potential is the limit of
the frequencies for \( n \to \infty \). The quantum defects can be
obtained by least-squares fits of the Bogoliubov frequen-
cies \( \omega_{nl} \) to Eq. (14). They converge to constant values
for large \( n \). Since Eq. (14) strictly holds only in this
limit, in the fits it can be necessary to neglect the lowest
frequencies.

For growing angular momentum, the repulsive effec-
tive potential \( l(l+1)/r^2 \) becomes stronger, and this cen-
trifugal barrier ensures that the absolute values of the
functions \( u \) and \( v \) decrease close to the origin \( r = 0 \).
This leads to a smaller quantum defect \( \delta_l \), since the
approximation made in deriving Eqs. (13) becomes valid
at smaller values of \( r \). In accordance with the quantum
defects in alkalis [26], the quantum defects therefore will
tend to zero for higher angular momenta.

In Fig. 7 we present the quantum defects calculated
for the Bogoliubov excitations of the ground state. Obvi-
ously the quantum defects for \( l = 0 \) and \( l = 1 \) show
a strong dependence on the scattering length, while for

Figure 5. (Color online) Frequencies of the Bogoliubov excita-
tions of the ground state of a self-trapped monopolar BEC for
a fixed scattering length \( a = -0.4 \), plotted for different values
of the angular momentum. The dotted line gives the value of
the chemical potential. Obviously, as observed in Fig. 2 and
Fig. 3, the frequencies converge to a common limit, which
is the chemical potential. The Bogoliubov spectrum can be
described by a Rydberg formula with quantum defects.

Figure 6. (Color online) (a) Wave function \( \psi_0 \) and (b)
mean-field potential \( \phi_0 \) for the ground state of a self-trapped
monopolar condensate at a scattering length of \( a = -0.4 \) as
functions of the radial coordinate \( r \). The wave function
behaves like \(-2/r\) for large values of \( r \). In this region, the
wave function can be neglected and the mean-field potential
replaced by its asymptotic form in the BDG equations.
$l \geq 2$ they are almost constant, and in particular close to zero for $l \geq 2$. Eq. (14) reproduces the frequencies of the Bogoliubov excitations of the ground state for all modes with an absolute error of less than $10^{-3}$, except for the two lowest $l = 0$ modes and the lowest $l = 1$ mode. The quantum defect analysis for the Bogoliubov excitations of the excited state is presented in Fig. 8. The quantitative statements made for the excitations of the ground state also hold for this state. The only difference is that the quantum defect for $l = 2$ tends to zero as the scattering length is increased.

Thus by means of quantum defect analysis we have been able to explain the Rydberg-like structure of the Bogoliubov spectra of the ground and excited state of self-trapped monopolar BECs, and could confirm that the negative chemical potential is the limit of the frequencies for all angular momenta.

III. VARIATIONAL APPROACH WITH GAUSSIAN FUNCTIONS AND SPHERICAL HARMONICS

We now turn our attention to variational calculations. The simplest ansatz with a single Gaussian centered at the origin was used by Perez-Garcia et al. [16] to determine monopolar and quadrupolar modes of BECs without long-range interactions. The ansatz was improved by using coupled Gaussians [17,18], and it was shown [1,2] that this method is capable of reproducing accurately the stationary states even of BECs with long-range interactions, calculated numerically. The ansatz employed to determine the stationary solution of a radially symmetric condensate was

$$\psi = \sum_{k=1}^{N} e^{-A_k^r r^2 - \gamma_k},$$

(15)

where the complex quantities $A_k^r$ and $\gamma_k$ are the widths and the amplitudes, respectively, of each Gaussian. The above ansatz can only describe monopolar excitation modes, since the wave function $\psi$ is independent of the angular coordinates $\theta$ and $\phi$. If one chooses the widths differently for each space direction,

$$\psi = \sum_{k=1}^{N} e^{-A_k^r x^2 - A_k^r y^2 - A_k^r z^2 - \gamma_k},$$

(16)

the width of a condensate can oscillate independently in each direction, which represents quadrupolar oscillations.

A generalization of Eqs. (15) and (16), which includes general square and linear terms in the exponentials, is

$$\psi = \sum_{k=1}^{N} g_k \equiv \sum_{k=1}^{N} \exp\left(-r^T A_k^r r - (p_k)^T r - \gamma_k \right),$$

(17)

with complex symmetric matrices $A_k^r$, complex vectors $p_k$ and complex numbers $\gamma_k$. This ansatz can describe excitation modes with angular momenta up to $l = 2$. To see this consider a small deviation $\delta z$ of the variational parameters from those of a stationary solution $z_0$ and Taylor expand the ansatz with coupled Gaussians [17] for the perturbed wave function $\psi(z_0 + \delta z)$ to first order...
\[ \delta \psi = \delta z \cdot \left. \frac{\partial \psi}{\partial z} \right|_{z=z_0} = -\sum_{k=1}^{N} \left( r^T \delta A_k^T r + (\delta p^k)^T r + \delta \gamma^k \right) g^k \bigg|_{z=z_0}. \]  

(18)

Since only terms at most quadratic in \( x, y, z \) appear in front of the exponentials, these terms can be expressed by spherical harmonics with angular momenta \( l, o 1, 2 \), which proves our statement.

We apply an ansatz which is capable of describing excitations with – in principle – arbitrary angular momenta. Motivated by the separation in the BDG equations with spherical harmonics in Eq. (9), we directly include the spherical harmonics in an extended variational ansatz

\[ \psi = \sum_{k=1}^{N} \left( 1 + \sum_{(l,m)\neq(0,0)} d^k_{lm} Y_{lm}(\theta, \phi) r^l \right) e^{-A_k^* r^2 - \gamma^k}. \]  

(19)

The amplitudes \( d^k_{lm} \) account for additional angular momenta \( (l, m) \). The sum over \( (l, m) \) may include arbitrary angular momenta, adjusted to the problem. For instance, if one wishes to calculate the linear perturbation of a specific angular momentum \( (l, m) \), as we do below, the sum in Eq. (19) needs to include \( (l, m) \) and \( (l, -m) \), since the nonlinear terms in the GPE lead to a coupling of different angular momenta.

A. Equations of motion and stability analysis

In order to carry out calculations with the extended variational ansatz (19), we need the equations of motion for the variational parameters. We use the approach of [1] based on the Dirac-Frankel-McLachlan time-dependent variational principle [27, 28]. An arbitrary ansatz for the wave function is made \( \psi = \psi(z) \), with the – in general complex – variational parameters \( z = (z_1, \ldots, z_M) \), for a system governed by the Schrödinger equation

\[ i \dot{\psi} = \hat{H} \psi, \]  

(20)

where the Hamiltonian \( \hat{H} \) may contain nonlinear terms in the wave function. The principle states that the norm of the difference between the left- and the right-hand side of (20)

\[ I = \|i \phi(t) - \hat{H} \psi(t)\|^2 \]  

(21)

must be minimized. For a fixed time \( t \), \( \psi(t) \) is given, and \( I \) is minimized by varying \( \phi(t) \). After the minimization, \( \phi \) is set to \( \phi = \dot{\psi} \). A necessary condition for the minimization of \( I \) is [15]

\[ K \dot{z} = -i h, \]  

(22)

the matrix \( K \) and the vector \( h \) are defined by

\[ K_{ij} = \left\langle \frac{\partial \psi}{\partial z_i}, \frac{\partial \psi}{\partial z_j} \right\rangle, \]  

(23a)

\[ h_i = \left\langle \frac{\partial \psi}{\partial z_i}, \hat{H} \psi \right\rangle. \]  

(23b)

Stationary solutions can then be found by requiring

\[ \dot{z}_i = -i \sum_{j=1}^{M} (K^{-1})_{ij} h_j = \left\{ \begin{array}{ll} i \mu & \text{for } z_i \equiv \gamma^k, \\ 0 & \text{else}, \end{array} \right. \]  

(24)

and searching for \( z \) in a nonlinear root search.

The stability properties and linear oscillations of a stationary solution \( z_0 \) can be found by first changing from the complex \( M \)-dimensional vector \( z \) to a real \( 2M \)-dimensional vector \( \tilde{z} \) containing the real and imaginary parts of the variational parameters, and considering a small perturbation, \( \tilde{z}(t) = z_0 + \delta \tilde{z}(t) \). Linearization of the equations of motion (22) yields the time dependency of the perturbation [1]

\[ \delta \tilde{z}(t) = J \delta \tilde{z}(t) \]  

(25)

with the Jacobian

\[ J_{ij} = \frac{\partial \tilde{z}_i}{\partial \tilde{z}_j} \]  

(26)

evaluated at the fixed point \( \tilde{z} = \tilde{z}_0 \). The excitation modes of the stationary solutions are finally found by diagonalizing the Jacobian \( J \).

All integrals appearing in Eq. (22) with the ansatz (19) can be calculated analytically. The contact interaction leads to integrals over four spherical harmonics which can be expressed in terms of Wigner-3j symbols. The contribution of long-range monopolar potential can be evaluated by inserting the multipole expansion for the monopole integration kernel, which leads to Gaussian integrals. For further details of the calculations we refer to the appendix.

B. Test in a system without long-range interactions

As a first test we apply the extended variational ansatz (19) to a condensate in a radially symmetric trap with short-range scattering interaction. The GPE for this system reads

\[ i \frac{\partial \psi}{\partial t}(r, t) = \left[ -\Delta + r^2 + 8\pi a |\psi(r, t)|^2 \right] \psi(r, t). \]  

(27)

Here units based on the trapping frequency \( \gamma = \omega/2 \) and the harmonic oscillator length \( a_0 = \sqrt{\hbar/m\omega} \) have been used. The scaled dimensionless scattering length \( a \) in (27) corresponds to \( Na/a_0 \) in SI units, with the particle number \( N \). These units will be used in all figures for the condensate without long-range interaction. The BDG
the auxiliary field

Interaction were first solved numerically by [29, 30]. In this work, we used the method discussed in Sec. IIB.

For comparison in Fig. 9, we also show the results for a fixed scattering length of \( a = -0.4 \) and angular momenta up to \( l = 6 \). For \( l = 0 \) the variational ansatz reproduces the Bogoliubov frequencies very well for the four lowest modes, and with only small deviations for the two lowest modes in the higher angular momentum bands.

within numerical accuracy, independent of the number of Gaussians used. For the higher modes with eigenvalues of the Jacobian \( \omega > 10 \), only far away from the critical point the variational and full-numerical results still approximately correspond to each other, and in the vicinity of the critical scattering length the Jacobi eigenvalues can reproduce the behavior of the Bogoliubov excitation eigenfrequencies only qualitatively.

We also tested the variational ansatz (19) for higher angular momenta up to \( l = 6 \). The results for a fixed scattering length of \( a = -0.4 \) are presented in Fig. 10. One recognizes a very good agreement for the lowest modes in each \( l \) band, and small differences for the second-lowest modes. This demonstrates that for condensates with attractive short-range interaction the eigenvalues of the Jacobian matrix calculated at the fixed point corresponding to the ground state in the new variational ansatz indeed quantitatively coincide with the eigenfrequencies of the lowest Bogoliubov modes.

C. Application of the variational approach to the monopolar condensate

We now apply the extended variational ansatz (19) to the self-trapped monopolar condensate. For the three lowest excitations Fig. 11 shows the comparison of the full-numerical Bogoliubov spectrum with the spectrum obtained from the eigenvalues of the Jacobian matrix in the variational ansatz. We used \( N = 6 \) Gaussians and angular momenta up to \( l = 3 \). The lowest modes for \( l = 0 \) and \( l = 1 \) match very well in the whole range of scattering lengths considered. For the second-lowest \( l = 0 \) and \( l = 1 \) and the lowest \( l = 2 \) mode we find a good agreement, but the differences become larger as the scattering

...
length approaches the critical point. Nevertheless, we have the result that the variational ansatz with coupled Gaussians and spherical harmonics is a valid alternative to the full-numerical quantum mechanical approach also in this case, if one is interested in these modes.

Looking at the lowest mode with $l = 3$ one finds that the agreement is good for scattering lengths around $a = 0$, but the two frequencies deviate as the scattering length is decreased. The eigenmode of the variational ansatz can only be seen as an approximation to the full-numerical one. The other modes can only be described qualitatively by the variational approach.

We also applied the variational ansatz (19) for higher angular momenta up to $l = 6$. The results for a fixed scattering length of $a = -0.4$ are presented in Fig. 12. As already noticed, only the lowest modes and angular momenta agree well with the numerically exact values. In the remaining modes the excitation frequencies differ distinctly. For $l = 5$, the frequency of the lowest mode even lies above the negative chemical potential, which could be identified as the upper limit of the Bogoliubov spectrum. Obviously, the variational ansatz with coupled Gaussians and spherical harmonics is not as appropriate for the self-trapped monopolar condensate as for the condensate without long-range interaction. To obtain still better results in the variational ansatz, it would be necessary to use more than $N = 6$ coupled Gaussians. This, however, leads to numerical difficulties, since the matrix $K$ in the equations of motion (22) becomes more and more ill-conditioned when the number of Gaussians is increased, which leads to an inaccurate solution of the linear system of equations.

IV. CONCLUSION AND OUTLOOK

We investigated the Bogoliubov spectrum of the self-trapped monopolar condensate full-numerically with the finite-difference method. With this method, we were able to calculate many modes for angular momenta from $l = 0$ to $l = 6$. We found a similar structure as in the spectra of alkali atoms. The behavior could be explained by quan-
tum defect theory, and it was found that practically the entire spectrum can be described by a simple Rydberg formula with quantum defects.

As an alternative to full-numerical calculations of condensate excitations a new variational ansatz was presented which combines coupled Gaussians with spherical harmonics. Using the time-dependent variational principle we could derive the equations of motion for the variational parameters. We applied the variational ansatz to two different systems. For condensates with an attractive short-range interaction we found that there is a good agreement between the quantum mechanical eigenfrequencies of the lowest Bogoliubov excitations and the eigenvalues of the Jacobian stability matrix. In this way we have been able to link the concepts of stability in quantum mechanics and in classical dynamical systems with each other.

For self-trapped condensates with additional $1/r$ interaction we also found a good agreement for the very lowest modes, but the variational ansatz works less well for higher modes. What is the reason for this? For the condensate without long-range interaction in an external trap, the confining radially symmetric harmonic potential dominates the properties of the system in a wide range of the scattering length. The contact interaction quasi acts as a perturbation. Therefore, a variational ansatz in which the radial part is determined by Gaussians is very well adapted to describe the stationary solutions and their excitations.

For the self-trapped monopolar condensate, on the other hand, an external trap is missing and the interactions alone determine the properties of the system. As pointed out in Sec. IID, the asymptotic form for $r \to \infty$ of the BDG equations is equivalent to the Schrödinger equation of the hydrogen atom. Therefore in that range the solutions $u$ and $v$ could be approximated by Laguerre polynomials and the exponential function $\exp(-\alpha r)$ with some $\alpha > 0$. A variational ansatz with coupled Gaussians and spherical harmonics is not well suited to reproduce this asymptotic behavior. However, as soon as a radially symmetric trap is switched on, the agreement between the quantum mechanical and the nonlinear dynamics excitations is present again also for the higher modes.

All together it was shown that especially in the case without long-range interactions the extended variational ansatz works well and can reproduce the lowest modes for arbitrary angular momenta, which is significant progress compared to the ansatz with coupled Gaussians only. If one is interested only in the lowest modes, the ansatz is a valid alternative to the full-numerical calculations.

So far, we only calculated the linear dynamics in the vicinity of a stationary solution. It remains to be shown whether or not the ansatz is capable of describing also the full nonlinear dynamics of a BEC. Furthermore, the present ansatz is restricted to radially symmetric systems. To calculate excitations of cylindrically symmetric systems with arbitrary angular momenta, which would be necessary, e.g., for condensates with dipole-dipole long-range interactions, an extension of the ansatz is required. For dipolar condensates such an ansatz would be of interest, since the dipolar interaction offers the new possibility for a condensate to collapse with $m = 2, 3, \ldots$ symmetry, the so-called angular collapse [8].

**Appendix: Integrals for the variational ansatz with coupled Gaussians and spherical harmonics**

We give the integrals necessary for setting up the equations of motion resulting from the time-dependent variational principle for the new variational ansatz Eq. (19). We need the matrix and vector

\begin{align}
K_{ij} &= \left\langle \frac{\partial \psi}{\partial z_i}, \frac{\partial \psi}{\partial z_j} \right\rangle, \\
h_i &= \left\langle \frac{\partial \psi}{\partial z_i}, \hat{H} \psi \right\rangle,
\end{align}

where the mean-field Hamiltonian $\hat{H}$ consists of four parts

\begin{align}
\hat{H} &= \hat{T} + V_{\text{ext}} + V_s + V_m \\
&= -\Delta + \gamma r^2 + 8\pi a |\psi(r)|^2 - 2 \int d^3r' \frac{|\psi(r')|^2}{|r - r'|},
\end{align}
To calculate the integrals, we write the ansatz \[ \psi = \sum_{k=1}^{N} \sum_{l,m} d_{l,m}^k Y_{lm}(\theta, \phi) r^l e^{-A^k r^2 - \gamma^k}, \] in a slightly different form

\[ \psi = \sum_{k=1}^{N} \sum_{l,m} d_{l,m}^k Y_{lm}(\theta, \phi) r^l e^{-A^k r^2 - \gamma^k}, \] \hspace{1cm} (A.3)

where all \( d_{l,0}^k \equiv 1 \) have to be treated as constants, and not as variational parameters.

### Integrals of the \( K \) matrix

For the elements of the \( K \) matrix, one needs the integrals over two spherical harmonics, which because of their orthogonality are given by Kronecker deltas, and the integrals over the radial coordinate, which are all of the form

\[ I_r = \int_0^\infty dr r^l \exp \left( -A r^2 \right). \] \hspace{1cm} (A.4)

With the substitution \( r \to t = A r^2 \), one can use the Gamma function to write

\[ I_r = \frac{1}{2} A^{-(l+1)/2} \Gamma[(l+1)/2]. \] \hspace{1cm} (A.5)

For the elements of the \( K \) matrix we then obtain, with the definitions \( A^{kl}_r \equiv A_r^k + (A_r^l)^* \) and \( \gamma^{kl} \equiv \gamma^k + (\gamma^l)^* \)

\[ \left\langle \frac{\partial \psi}{\partial d_{l_{2},m_{2}}^k} \right| \frac{\partial \psi}{\partial d_{l_{1},m_{1}}^k} \right\rangle = \frac{1}{2} \delta_{l_{1},l_{2}} \delta_{m_{1},m_{2}} \Gamma[(l+3/2)]_{l_{1}+3/2} e^{-\gamma^{kl}}, \] \hspace{1cm} (A.6)

\[ \left\langle \frac{\partial \psi}{\partial d_{l_{1},m_{1}}^k} \right| \frac{\partial \psi}{\partial A^k_r} \right\rangle = -\frac{1}{2} \delta_{l_{1},l_{2}} \Gamma[(l+5/2)]_{l_{2}+5/2} e^{-\gamma^{kl}}, \] \hspace{1cm} (A.7)

\[ \left\langle \frac{\partial \psi}{\partial d_{l_{1},m_{1}}^k} \right| \frac{\partial \psi}{\partial \gamma^k} \right\rangle = -\frac{1}{2} \delta_{l_{1},l_{2}} \Gamma[(l+3/2)]_{l_{2}+3/2} e^{-\gamma^{kl}}, \] \hspace{1cm} (A.8)

\[ \left\langle \frac{\partial \psi}{\partial A^l_r} \right| \frac{\partial \psi}{\partial d_{l_{1},m_{1}}^k} \right\rangle = \frac{1}{2} \sum_{l_{1},m_{1}} (d_{l_{1},m_{1}}^k)^* d_{l_{1},m_{1}}^k \Gamma[(l+7/2)]_{l_{1}+7/2} e^{-\gamma^{kl}}, \] \hspace{1cm} (A.9)

\[ \left\langle \frac{\partial \psi}{\partial A^l_r} \right| \frac{\partial \psi}{\partial \gamma^l} \right\rangle = \frac{1}{2} \sum_{l_{1},m_{1}} (d_{l_{1},m_{1}}^k)^* d_{l_{1},m_{1}}^k \Gamma[(l+5/2)]_{l_{1}+5/2} e^{-\gamma^{kl}}, \] \hspace{1cm} (A.10)

\[ \left\langle \frac{\partial \psi}{\partial \gamma^l} \right| \frac{\partial \psi}{\partial d_{l_{1},m_{1}}^k} \right\rangle = \frac{1}{2} \sum_{l_{1},m_{1}} (d_{l_{1},m_{1}}^k)^* d_{l_{1},m_{1}}^k \Gamma[(l+3/2)]_{l_{1}+3/2} e^{-\gamma^{kl}}. \] \hspace{1cm} (A.11)

### Integrals of the kinetic term

For the calculation of the integrals of the kinetic term, one lets the Laplacian act on the variational ansatz. The integrals of the resulting terms can then be evaluated using Eq. (A.5), which leads to

\[ \left\langle \frac{\partial \psi}{\partial d_{l_{2},m_{2}}^k} \right| T \psi \right\rangle = \frac{1}{2} \sum_{k=1}^{N} d_{l_{1},m_{1}}^k \left[ (4l_2 + 6)A_r^k \Gamma[(l_2 + 3/2)]_{l_2+3/2} - 4(A_r^k)^2 \Gamma[(l_2 + 5/2)]_{l_2+5/2} \right] e^{-\gamma^{kl}}, \] \hspace{1cm} (A.12)

\[ \left\langle \frac{\partial \psi}{\partial A^l_r} \right| T \psi \right\rangle = \frac{1}{2} \sum_{k=1}^{N} \sum_{l_{1},m_{1}} (d_{l_{1},m_{1}}^k)^* d_{l_{1},m_{1}}^k \left[ (4l_1 + 6)A_r^k \Gamma[(l_1 + 5/2)]_{l_1+5/2} - 4(A_r^k)^2 \Gamma[(l_1 + 7/2)]_{l_1+7/2} \right] e^{-\gamma^{kl}}, \] \hspace{1cm} (A.13)

\[ \left\langle \frac{\partial \psi}{\partial \gamma^l} \right| T \psi \right\rangle = \frac{1}{2} \sum_{k=1}^{N} \sum_{l_{1},m_{1}} (d_{l_{1},m_{1}}^k)^* d_{l_{1},m_{1}}^k \left[ (4l_1 + 6)A_r^k \Gamma[(l_1 + 3/2)]_{l_1+3/2} - 4(A_r^k)^2 \Gamma[(l_1 + 5/2)]_{l_1+5/2} \right] e^{-\gamma^{kl}}. \] \hspace{1cm} (A.14)

### Integrals of the trapping potential

The integrals for the trapping potential are straightforward:

\[ \left\langle \frac{\partial \psi}{\partial d_{l_{2},m_{2}}^k} \right| V_{\text{ext}} \psi \right\rangle = \frac{1}{2} r^2 \sum_{k=1}^{N} d_{l_{1},m_{1}}^k \Gamma[(l_2 + 5/2)]_{l_2+5/2} e^{-\gamma^{kl}}, \] \hspace{1cm} (A.15)
An analytical expression for the product of two spherical harmonics can be expressed

\[ \langle \frac{\partial \psi}{\partial \gamma} | V_{\text{ext}} | \psi \rangle = \frac{1}{2} \gamma_i^2 \sum_{k=1}^{N} \sum_{l_i, m_i} (d_{l_i m_i}^*)^* d_{l_i m_i} \times \frac{\Gamma(l_i + 5/2)}{(A_f^k l_i + 5/2)} e^{-\gamma_{ki}}. \] (A.17)

Integrals of the scattering term

To write down the integrals of the scattering term, we introduce the new abbreviations \( A_{ijkl} = A_{ij} + A_{kl} \), \( \gamma_{ijkl} = \gamma_{ij} + \gamma_{kl} \), and for the integral over four spherical harmonics the notation

\[ I_{\Omega}^{(4)}(l_1, m_1; l_2, m_2; l_3, m_3; l_4, m_4) = \int d\Omega Y_{l_1 m_1}(\theta, \phi) Y_{l_2 m_2}(\theta, \phi) Y_{l_3 m_3}(\theta, \phi) Y_{l_4 m_4}(\theta, \phi), \] (A.18)

where \( d\Omega = d\phi d\theta \sin \theta \) is the differential solid angle element of the angular coordinates. Using again Eq. (A.5), we obtain for the integrals

\[ \langle \frac{\partial \psi}{\partial l_{12}^2} | V_{l_{12}} | \psi \rangle = 4\pi a \sum_{i,j,k=1}^{N} \sum_{l_1 m_1, l_2 m_2} \sum_{l_3 m_3, l_4 m_4} \sum_{l_1 m_1} (-1)^{m_2+m_4} (d_{l_2 m_2}^*)^* d_{l_3 m_3} d_{l_4 m_4} \frac{\Gamma(l_1 + l_2 + l_3 + l_4 + 3/2)}{(A_f^k l_1 + 5/2)} e^{-\gamma_{ijkl}}, \] (A.19)

\[ \langle \frac{\partial \psi}{\partial A_f^k} | V_{l_{12}} | \psi \rangle = -4\pi a \sum_{i,j,k=1}^{N} \sum_{l_1 m_1, l_2 m_2} \sum_{l_3 m_3, l_4 m_4} \sum_{l_1 m_1} (-1)^{m_2+m_4} (d_{l_2 m_2})^* (d_{l_4 m_4})^* d_{l_3 m_3} d_{l_4 m_4} \frac{\Gamma(l_1 + l_2 + l_3 + l_4 + 5/2)}{(A_f^k l_1 + 5/2)} e^{-\gamma_{ijkl}}, \] (A.20)

\[ \langle \frac{\partial \psi}{\partial \gamma_i} | V_{l_{12}} | \psi \rangle = -4\pi a \sum_{i,j,k=1}^{N} \sum_{l_1 m_1, l_2 m_2} \sum_{l_3 m_3, l_4 m_4} \sum_{l_1 m_1} (-1)^{m_2+m_4} (d_{l_2 m_2})^* (d_{l_4 m_4})^* d_{l_3 m_3} d_{l_4 m_4} \frac{\Gamma(l_1 + l_2 + l_3 + l_4 + 3/2)}{(A_f^k l_1 + 5/2)} e^{-\gamma_{ijkl}}. \] (A.21)

An analytical expression for \( I_{\Omega}^{(4)} \) is found by noting that the product of two spherical harmonics can be expressed by a series of spherical harmonics

\[ Y_{l_1 m_1}(\theta, \phi) Y_{l_2 m_2}(\theta, \phi) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} C_l^{m_1 m_2} C_l^{-m_3 m_4} Y_{l m_1}(\theta, \phi), \] (A.22)

where the coefficients \( C_l^{m_1 m_2} \) can be written in terms of Wigner 3j symbols

\[ C_l^{m_1 m_2} = (-1)^m \sqrt{\frac{(2l_1 + 1)(2l_2 + 1)(2l + 1)}{4\pi}} \times \begin{pmatrix} l_1 & l_2 & l \\ l_1 & l_2 & l \\ m_1 & m_2 & -m \end{pmatrix}. \] (A.23)

Applying this expansion twice in the integral Eq. (A.18), we obtain

\[ I_{\Omega}^{(4)}(l_1, m_1; l_2, m_2; l_3, m_3; l_4, m_4) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} (-1)^m C_l^{-m_3 m_4} C_l^{m_1 m_2} \Gamma[l_1 l_2 l_3 l_4]. \] (A.24)

Integrals of the monopolar term

The infinite sum can be cut off, since a Wigner 3j symbol is zero, if the triangle inequalities \( |l_1 - l_2| \leq l \leq l_1 + l_2 \) or \( |l_3 - l_4| \leq l \leq l_3 + l_4 \) are not fulfilled, and \( l_1, \ldots, l_4 \) cannot be greater than the largest angular momentum included in the variational ansatz.
with the definition

$$I_{m,p} = \int d\Omega \int_0^\infty dr \int d\Omega' \int_0^\infty dr' \frac{1}{|r - r'|} Y_{lm}^*(\theta, \phi) Y_{lm}(\theta', \phi').$$

(A.29)

The integral $I_{m,p}$ then separates into two integrals over the angular coordinates $\Omega, \Omega'$, which can be expressed with the coefficients $C_{lm,m'}$, from Eq. A.23, and one integral over the radial coordinates $r, r'$, which is of Gaussian type and can be solved analytically. For $I_{m,p}$ we obtain

$$I_{m,p} = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \frac{4\pi}{2l + 1} f_m f_{m'} r r' I_m^{l} I_{m'}^{l'} r_{m'}^{r_{m'}}.$$  

(A.30)

with the individual integrals

$$I_m^{l} = (-1)^m C_{l_2}^{m_2 - m_1} l_1 l_2,$$

(A.31)

$$I_{m'}^{l'} = C_{l_3}^{m_3} l_1 l_2,$$

(A.32)

and

$$I_{m,p}^{r r'} = \frac{1}{4} \left( \frac{A_{r}^{kij}}{A_{r'}^{kl}} \right)^\alpha \frac{[(l_3 + l_4 - l)/2]!}{(l_3 + l_4 - l + 2\alpha + 3)/2} \sum_{\alpha=0}^{l_3+l_4-l+p} \frac{1}{\alpha!} \left( \frac{A_{r}^{kij}}{A_{r'}^{kl}} \right)^\alpha \Gamma[(l_3 + l_4 + l + 2\alpha + 3)/2].$$

(A.33)

The infinite sum in Eq. (A.30) can be cut off again due to the properties of the Wigner 3j symbols. Thus all integrals necessary for setting up the equations of motion for the variational parameters for the ansatz with coupled Gaussians and spherical harmonics have been calculated analytically.
