(Dated: September 24, 2009)

The polarizabilities and hyperpolarizabilities of the Be\(^+\) ion in the \(2\, ^2S\) state and the \(2\, ^2P\) state are determined. Calculations are performed using two independent methods: \(i)\) variationally determined wave functions using Hylleraas basis set expansions and \(ii)\) single electron calculations utilizing a frozen-core Hamiltonian. The first few parameters in the long-range interaction potential between a Be\(^+\) ion and a H, He, or Li atom, and the leading parameters of the effective potential for the high-\(L\) Rydberg states of beryllium were also computed. All the values reported are the results of calculations close to convergence. Comparisons are made with published results where available.

PACS numbers: 31.15.ac, 31.15.ap, 34.20.Cf

I. INTRODUCTION

Studies of the Be\(^+\) ion are of interest due to its importance in a number of applications. First, the Be\(^+\) ion is used as an auxiliary ion to sympathetically cool other atomic or ionic species [1, 2] that cannot be directly laser cooled due to the lack of closed optical transitions. Second, the Be\(^+\) ion can combine with other atoms or neutral molecules to form molecular ions, such as BeH\(^+\) [3, 4, 5, 6], and the study of the long-range interaction between a Be\(^+\) ion and atoms or molecules may open new routes for the study of state-elective chemical reactions relevant to astrophysics [3]. Third, investigations of Be\(^+\) ion collisions with rare gases would be useful in the study of ion-atom Feshbach resonances [7], pressure broadening of alkaline-earth-metal ions [8], and
in studies of excitation spectroscopy of the collision [9, 10]. Fourth, since beryllium has a number of isotopes, studies of the Be$^+$ ion could potentially be used to determine the nuclear charge radii of beryllium isotopes [11]. Finally, there is interest in studying the spectrum of the alkaline-earth-metal atom in high angular momentum Rydberg states. Experimental investigations have been made on a number of atoms [12, 13, 14, 15] with a view to determining the polarizabilities of the singly ionized parent ion. These experiments measure the high $(n,L)$ energy splitting and then use a polarization model to extract the polarizabilities. Recent calculations [16] have shown the polarization model to be sensitive to nonadiabatic effects. The Be$^+$ ion would be a useful candidate for a validation experiment since it should be less sensitive to adiabatic effects and its polarizabilities can be calculated to very high precision.

The above physical phenomena are influenced by the properties of the Be$^+$ ion, and in particular the polarizabilities and hyperpolarizabilities. There have been several calculations of the Be$^+$ ion polarizabilities reported in the literature. These include the work by Adelman and Szabo [17] using the Coulomb-like approximation, the calculation by Pipin and Woznicki [18] using the variation-perturbation approach with a combined Hylleraas-configuration interaction (CI) basis set, the calculation by Patil and Tang [19] using the valence electron binding energy to construct wave functions constrained to have the correct long-range asymptotic behavior, and finally the large basis full core plus configuration interaction (FCCI) calculations by Wang and collaborators [20, 21, 22, 23, 24, 25]. However, there have been no calculations reported on the polarizabilities and hyperpolarizabilities for the Be$^+$ ion excited states.

In this paper, the polarizabilities, hyperpolarizabilities and some long range ion-atom dispersion coefficients involving Be$^+$ ion are computed with two independent methods. First, oscillator strengths for many low-lying transitions are determined. Next, the polarizabilities and hyperpolarizabilities for the $2^2S$ state and $2^2P$ state of Be$^+$ ion are computed variationally using expansions of the wave functions in Hylleraas bases. The same set of long-range parameters are also computed using a fixed core plus semi-empirical polarization potential to describe the valence electron. The agreement between the two different calculations will be seen to be excellent. The long-range dispersion interactions between Be$^+$ ion and the H, He or Li atoms are given and once again the agreement between the two sets of calculations is excellent. Furthermore, we compute all the parameters needed to define a Be$^+$ polarization potential (including terms up to $r^{-8}$) to describe the high-$L$ Rydberg states of beryllium, where $r$ is the ion-electron distance. All results of this paper are given in atomic units ($e = h = m_e = 1$).
II. THEORY AND METHOD

A. Hylleraas variational method

The calculations for Be\(^+\) ion are very similar in style to those for Li [26, 27]. In the center of mass frame, the nucleus is taken as the reference particle 0, with mass \(m_0\) and charge \(q_0\), \(r_i\) is the electron-nucleus distance, and \(i = 1, 2, 3\). The nonrelativistic Hamiltonian of this system can be written in the form

\[
H_0 = -\sum_{i=1}^{3} \frac{1}{2\mu_i} \nabla_i^2 - \frac{1}{m_0} \sum_{i>j \geq 1}^3 \nabla_i \cdot \nabla_j + q_0 \sum_{i=1}^{3} \frac{q_i}{r_i} + \sum_{i>j \geq 1}^3 \frac{q_i q_j}{r_{ij}},
\]

(1)

where \(r_{ij} = |r_i - r_j|\) is the distance between electrons \(i\) and \(j\), \(q_i\) are the charge of the three electrons, and \(\mu_i = m_i m_0 / (m_i + m_0)\) is the reduced mass between the \(i\)th electron and the nucleus. In the present paper, all the calculations are done in the infinite nuclear mass approximation.

Significant progress has been made recently in variational calculations for three electron systems by using multiple basis sets in Hylleraas coordinates [28, 29]. These have the functional form,

\[
\phi = r_1^{j_1} r_2^{j_2} r_3^{j_3} r_{12}^{j_{12}} r_{23}^{j_{23}} r_{31}^{j_{31}} e^{-\alpha r_1 - \beta r_2 - \gamma r_3} Y^{LM}_{\ell_1 \ell_2 \ell_3}(\hat{\mathbf{r}}_1, \hat{\mathbf{r}}_2, \hat{\mathbf{r}}_3) \chi(1, 2, 3),
\]

(2)

where \(Y^{LM}_{\ell_1 \ell_2 \ell_3}\) is a vector-coupled product of spherical harmonics to form an eigenstate of total angular momentum \(L\) and projection \(M_L\), and \(\chi(1, 2, 3)\) is the three-electron spin function. The variational wave function is a linear combination of anti-symmetrized basis functions \(\phi\). With some truncations to avoid potential numerical linear dependence, all terms in Eq. (2) are included such that

\[
j_1 + j_2 + j_3 + j_{12} + j_{23} + j_{31} \leq \Omega,
\]

(3)

where \(\Omega\) is an integer, and the convergence for the energy eigenvalue is studied by progressively increasing \(\Omega\).

For the He atom, taking the nucleus as the reference particle 0, the electron is labeled as particle 1 and the other electron is labeled as particle 2. The wave functions are expanded in terms of the explicitly correlated basis set in Hylleraas coordinates:

\[
\phi = r_1^{j_1} r_2^{j_2} e^{-\alpha r_1 - \beta r_2} Y^{LM}_{\ell_1 \ell_2}(\hat{\mathbf{r}}_1, \hat{\mathbf{r}}_2).
\]

(4)

For the hydrogen atom, we use a basis set of form

\[
\phi = r^{\ell} e^{-\beta r / 2} L^{(2\ell+2)}_n(\beta r) Y_{\ell m}(\hat{\mathbf{r}}),
\]

(5)
where \( L_n^{(2\ell+2)}(\beta r) \) is the generalized Laguerre polynomial and the parameter \( \beta \) is chosen to be \( \beta = 2/(\ell + 1) \). This basis set has been proven to be numerically stable as the size of the basis set is increased.

### B. Single electron model

The detailed description of the procedure used to construct the frozen-core Hamiltonian and the semi-empirical polarization potential can be found in previous works by Mitroy and collaborators [16, 30, 31]. Accordingly, only the briefest description is given here.

Initially, a Hartree-Fock calculation of the Be\(^+\) ion ground state was performed. The core orbitals were then fixed, and a semi-empirical core polarization potential was added to the Hamiltonian. The core dipole polarizability was taken to be 0.0523 [30]. The cutoff parameters in the semi-empirical core polarization potential were \( \rho_0 = 0.941 \), \( \rho_1 = 0.895 \), \( \rho_2 = 1.200 \) with all other \( \rho_L \) set to 1.00 [30]. These values were chosen to reproduce the binding energies of the low-lying states.

The low-lying states and pseudo-continuum states were obtained by diagonalizing the fixed core Hamiltonian in a large basis of Laguerre type orbitals. Typically, there were about 50 orbitals for each value of the valence angular momentum. This is large enough to eliminate the basis as a significant source of error.

The multipole matrix elements and oscillator strengths were computed with a modified transition operator [30]. The adjustable parameter in the modified multiple operator was set to \( \rho = 1.00 \). Core excitations are included in the dispersion parameter calculation. Oscillator strength distributions were constructed from independent estimates of the core polarizabilities (\( \alpha_2 = 0.01532 \) [30] and \( \alpha_3 = 0.01125 \) [32]). The calculations using this approach are termed the Hartree-Fock plus core polarization (HFCP) model.

The dispersion coefficient calculations involving H and He used matrix element lists that were generated using basis functions that were similar (but not identical) in construction to Eq. (4) and (5). The matrix element lists for the Li atom came from a one electron model as described in Ref. [33].
C. Polarizabilities

Using perturbation theory, the adiabatic long-range interaction potential for an ion-atom system up to the $R^{-8}$ term can be written [34] as

$$V_{ab}(R) = -\frac{1}{2} Q_a^2 \sum_{\ell=1}^{3} \frac{\alpha^{(b)}_{\ell}}{R^{2\ell+2}} - \sum_{n=3}^{4} \frac{C_{2n}}{R^{2n}},$$

(6)

where $Q_a = \sum_i Q_i$ is the total charge of the ion $a$, $\alpha^{(b)}_{\ell}$ is the $2\ell$-pole static polarizabilities for the atom $b$, $R$ is the distance between the ion and the atom, and the $C_{2n}$ parameters are the dispersion coefficients. The first term in Eq. (6) is the polarization interaction, which does not lead to a frequency shift between the different states of the ion. The second term is the dispersion interaction, which can lead to a frequency shift between two different ion states when the ion is immersed in a buffer gas. From Eq. (6), we see that the establishment of the interaction potential $V_{ab}(R)$ accurate to $R^{-8}$ requires the static polarizabilities $\alpha_1$, $\alpha_2$, and $\alpha_3$ for the atom $b$, and the dispersion coefficients $C_6$ and $C_8$ between ion $a$ and atom $b$. Once we have obtained the oscillator strength spectra between the ground states and the intermediate states for the H, He, Li, and Be$^+$ ion systems, we can calculate the Be$^+$ ion polarizabilities, and the dispersion coefficients for various combinations of these particles. The detailed derivation of the formulae for calculating the polarizabilities, hyperpolarizabilities and dispersion coefficients in Hylleraas coordinates can be found in the Ref. [26].

For the high-$L$ Rydberg states of an atom or an ion, where a single electron is in highly excited state but still moves in the field of a spherically symmetric core, the polarization interaction between the core and a single Rydberg electron leads to the effective potential [12, 13, 16, 35, 36],

$$V_{\text{eff}}(r) = -\frac{A_4}{r^4} - \frac{A_6}{r^6} - \frac{A_7}{r^7} - \frac{A_8}{r^8} - \frac{A_8 L(L+1)}{r^8} + \cdots,$$

(7)

where $r$ is the radial coordinate of the Rydberg electron and the coefficients $A_n$ are properties of the free ion core. Comparisons with high precision variational calculations of the Rydberg states for the few-body systems, He [37], Li [21], and H$_2$ [38] have been made. This functional form has also been used to analyze the fine structure spectrum of the Rydberg states of neutral Mg and Ba, resulting in estimates of the dipole polarizabilities of the alkali-earth-metal ions Mg$^+$ and Ba$^+$ ground states [12, 14, 31].

According to definitions given previously [31, 35, 39], the leading coefficient $A_4$ is half the size of the static dipole polarizability,

$$A_4 = \frac{\alpha_1}{2},$$

(8)
with
\[
\alpha_1 = \frac{8\pi}{9} \sum_n \frac{|\langle n_00\|T_1\|n1\rangle^2}{E_n - E_0}.
\]
(9)

The notation \(|nL\rangle\) indicates the intermediate state with main quantum number \(n\) and angular momentum number \(L\), and \(T_1\) is the dipole transition operator, which satisfies the general expression for the \(2^\ell\)-pole transition operator in the center of mass frame,
\[
T_\ell = \sum_{i=1}^{3} q_i r_i^\ell Y_0(\hat{\mathbf{r}}_i).
\]
(10)

The notation \(|nL\rangle\) indicates the intermediate state with main quantum number \(n\) and angular momentum number \(L\), and \(T_1\) is the dipole transition operator, which satisfies the general expression for the \(2^\ell\)-pole transition operator in the center of mass frame,
\[
T_\ell = \sum_{i=1}^{3} q_i r_i^\ell Y_0(\hat{\mathbf{r}}_i).
\]
(10)

The next term \(A_6\) is composed of two separate terms,
\[
A_6 = \frac{\alpha_2 - 6\beta_1}{2},
\]
(11)

where \(\alpha_2\) is the quadrupole polarizability and \(\beta_1\) is the first order nonadiabatic correction to dipole polarizability. They are defined as
\[
\alpha_2 = \frac{8\pi}{25} \sum_n \frac{|\langle n_00\|T_2\|n2\rangle^2}{E_n - E_0},
\]
(12)
\[
\beta_1 = \frac{4\pi}{9} \sum_n \frac{|\langle n_00\|T_1\|n1\rangle^2}{(E_n - E_0)^2}.
\]
(13)

The \(r^{-7}\) term \(A_7\) also comes from two parts, namely,
\[
A_7 = -\frac{5\eta + 16q\delta_1}{10},
\]
(14)

where \(q\) is the charge on the core. \(\eta\) arises from third order perturbation theory and it can be expressed as
\[
\eta = \frac{32\pi\sqrt{10\pi}}{225} \sum_{m,n} \frac{\langle n_00\|T_1\|m1\rangle\langle m1\|T_1\|n2\rangle\langle n2\|T_2\|n0\rangle}{(E_m - E_0)(E_n - E_0)} + \frac{16\pi\sqrt{6\pi}}{135} \sum_{m,n} \frac{\langle n_00\|T_1\|m1\rangle\langle m1\|T_2\|n1\rangle\langle n1\|T_1\|n0\rangle}{(E_m - E_0)(E_n - E_0)},
\]
(15)

and \(\delta_1\) is the second order nonadiabatic correction to the dipole polarization energy,
\[
\delta_1 = \frac{4\pi}{18} \sum_n \frac{|\langle n_00\|T_1\|n1\rangle^2}{(E_n - E_0)^3}.
\]
(16)

Quite a few terms contribute to \(A_8\),
\[
A_8 = \frac{\alpha_3 - 15\beta_2 + \epsilon - \alpha_1\beta_1 + 72\delta_1}{2}.
\]
(17)
The octupole polarizability $\alpha_3$ is computed by
\[
\alpha_3 = \frac{8\pi}{49} \sum_n \left| \langle n_0|T_3|n3 \rangle \right|^2, \tag{18}
\]
while $\beta_2$ comes from the first nonadiabatic correction part to the quadrupole polarization energy, and is defined as
\[
\beta_2 = \frac{4\pi}{25} \sum_n \left| \langle n_0|T_2|n2 \rangle \right|^2 \frac{(E_n - E_0)^2}{(E_n - E_0)^2}. \tag{19}
\]
The term $\epsilon$ is defined
\[
\epsilon = \frac{32\pi^2}{81} \sum_{m,n} \left| \langle n_0|T_1|m1 \rangle \langle m1|T_1|n0 \rangle \right|^2 \frac{(E_m - E_0)^2}{(E_n - E_0)^2} + \frac{64\pi^2}{405} \sum_{m,n} \left| \langle n_0|T_1|m1 \rangle \langle m1|T_1|n2 \rangle \right|^2 \frac{(E_m - E_0)^2}{(E_n - E_0)^2}. \tag{20}
\]
The hyperpolarizability $\gamma_0$ of the ground state, and coefficients $\epsilon$, $\alpha_1$, $\beta_1$ are related by the identity $\gamma_0 = 12(\epsilon - \alpha_1\beta_1)$. The last term $A_{8L}$ is nonadiabatic in origin and defined by
\[
A_{8L} = \frac{18\delta_1}{5}. \tag{21}
\]
For excited states, the working expressions for the evaluation of the polarizabilities $\alpha_1$, $\alpha_T^1$, $\alpha_2$, and $\alpha_3$ and hyperpolarizabilities $\gamma_0$ and $\gamma_2$ are given in Tang et al [26]. These expressions are quite lengthy and not reproduced here.

D. Dispersion interactions

The dispersion interaction, between two atoms, $A$ and $B$, for the Hylleraas wave functions was calculated from tabulated lists of matrix elements using sum rules [26]. For the case of $C_6$ involving two $S$-state atoms, one can write the sum rule
\[
C_6 = \frac{3}{2} \sum_{m,n} \Delta E_{m0}^A \Delta E_{m0}^B (\Delta E_{m0}^A + \Delta E_{m0}^B) . \tag{22}
\]
The sum is over all states of $P^o$-symmetry. The absorption oscillator strength, $f_{0n}$, for a dipole transition from $0 \to n$, with an energy difference of $\Delta E_{m0} = E_0 - E_m$, is most conveniently defined in the present context [27, 30] as
\[
f_{0n} = \frac{2|\langle \psi_0; L_0 && rC^1(\hat{r}) \parallel \psi_n; L_n \rangle|^2 \Delta E_{m0}}{3(2L_0 + 1)}. \tag{23}
\]
In this expression for the HFCP method, $L_0$ is the ground state orbital angular momentum, and 
$rC^1(\hat{r}) = \sqrt{\frac{4\pi}{3}} r Y^1(\hat{r})$ is the operator for a dipole transition just for one electron. Explicit expressions for $C_8$, and $C_{10}$, and for other symmetries can be found in [26].

The dispersion interaction calculations for the HFCP wave functions utilized the completely general procedures outlined by Zhang and Mitroy [40, 41]. These calculations utilize sum rules involving lists of reduced matrix elements of the multipole operator $r^k C^k$ multiplied by angular recoupling factors. They are effectively equivalent to Eq. (22) and the expressions in [26] despite the differences how the calculations are actually carried out.

III. RESULTS AND DISCUSSION

A. The energies and oscillator strengths of Be$^+$ ion

Table I shows the convergence study for the nonrelativistic energy of the Be$^+$ ion ground state as the size of the Hylleraas basis set is enlarged. The ratio $R(\Omega)$ is defined by

$$R(\Omega) = \frac{E(\Omega - 1) - E(\Omega - 2)}{E(\Omega) - E(\Omega - 1)}.$$  (24)

The extrapolation was done by assuming that the ratio would stay constant around $R(\Omega) = 4.839$. It is clear from Table I that the energy converges to high precision as the number of terms is progressively increased. The final nonrelativistic energy is accurate to about 11 significant figures for the ground state. The uncertainty in the final energy is set to be equal to the extrapolation correction. The nonrelativistic theoretical energies for other low-lying states of Be$^+$ ion are tabulated and compared with experimental binding energies in Table II. Binding energies from the HFCP calculations are also listed. The Hylleraas binding energies are generally in good agreement with the experimental binding energies. There are two effects which change the binding energies, finite mass and relativistic effect. The finite mass effect will be about 0.001% and will probably act to decrease the magnitude of the binding energy. The largest discrepancy for the $2^2S$ state is due entirely to relativistic effects (see Table III of [29]), which contributes about 0.007% of the final value.

Table III lists the oscillator strengths for a number of the Be$^+$ ion dipole transitions involving low-lying states. The final values for the Hylleraas calculations are obtained with an extrapolation procedure similar to that for the energy. Once again the uncertainty in the oscillator strength is assigned to be equal to the magnitude of the extrapolation correction. It is evident from Table III that there is excellent agreement between the Hylleraas and HFCP calculations. The largest
discrepancy between the two calculations is only about 0.1\% (for the \(3^{2}P \rightarrow 3^{2}D\) transition). The oscillator strengths from the Hylleraas calculation could be used to improve the National Institute of Standards and Technology (NIST) tabulations [42, 43].

The Hylleraas oscillator strength for the \(2^{2}S \rightarrow 2^{2}P\) transition is accurate to about 7 significant figures and is compatible with an earlier Hylleraas calculation by Yan et al. [44]. Some earlier large scale ab-initio calculations also gave oscillator strengths that are compatible with the present Hylleraas calculation for this transition. These include the multi-configuration Hartree-Fock (MCHF) calculation of Godefroid et al. [45] and the FCCI calculation of Chung et al [22]. While the present oscillator strengths are reported with 7 significant digits, finite-mass and relativistic effects that are not included in the calculation could conceivably alter the oscillator strengths beginning at the fifth digit.

There have also been some high precision oscillator strengths reported for the \(2^{2}P \rightarrow 3^{2}D\) transition. The MCHF value of Godefroid et al. [45] and the FCCI value of Qu et al. [23] agree with the Hylleraas calculation to better than four digits. Qu et al. [24, 25] have also reported CI calculations for the \(2^{2}S \rightarrow 3^{2}P\) and \(3^{2}D \rightarrow 4^{2}F\) transition and again there is agreement to better than four significant digits. The experimental oscillator strengths listed in the Table were measured using beam-foil spectroscopy [46]. These oscillator strengths have only low precision and cannot discriminate between the higher quality theoretical estimates.

B. Polarizabilities of the Be\(^{+}\) ion

The convergence properties of the static dipole polarizability \(\alpha_1\), and hyperpolarizability \(\gamma_0\) for the Be\(^{+}\) ion ground state are presented in Table IV. Both of them have converged to five significant figures. The extrapolation was done by assuming that the ratio between two successive differences would stay constant as the basis size increased towards infinity. The uncertainty in the final value is set equal to the magnitude of the extrapolation correction from the explicitly calculated value computed with the basis of largest dimension.

Table V shows the convergence as a function of basis size for the scalar and tensor dipole polarizabilities \(\alpha_1, \alpha_1^T\), and the hyperpolarizabilities \(\gamma_0, \gamma_2\) for the first excited state of Be\(^{+}\) ion. The intermediate sums in this case have contributions from doubly excited unnatural parity states with \(L^\pi = 1^e\) and \(L^\pi = 2^o\) (e.g. the unnatural parity \(1^e\) state has two \(\ell = 1\) electrons coupled to a total angular momentum of \(L = 1\)). The contribution from the unnatural parity states is usually small. For example, the unnatural parity \(P^e\) states contribution of 0.020616 to \(\alpha_1\) is about 1\%. The scalar
dipole polarizability is converged to five significant digits, and the tensor dipole polarizability $\alpha_T^1$ is converged to six digits. The hyperpolarizabilities, $\gamma_0$ and $\gamma_2$ are accurate to the six and five significant figures respectively. There was no major numerical cancellation in the hyperpolarizabilities in our calculation, in contrast to the situation that prevails for the Li hyperpolarizability, which suffers severely from cancellations in the different parts of the calculation [26].

There have been a number of accurate calculations of the multipolar polarizabilities for the Li atom in its ground or lowest excited states [26, 33, 50]. However, there have been fewer polarizability calculations for the Be$^+$ ion in its ground and lowest energy excited state. Table VI gives a comparison between the present results and previous calculations for the static polarizabilities of Be$^+$ ion in the $2^2S$ and $2^2P$ states. One of the most notable features of the Table is the very good agreement between the Hylleraas and HFCP multipole polarizabilities. The overall level of agreement is at the 0.1% level. The one exception was the static dipole polarizability of the $2^2P$ state, but it should be noted that this polarizability is small due to cancellation between different terms in the oscillator strength sum. The polarizability of Be$^+(2^2P)$ state is relatively small because the Be$^+(2^2P \rightarrow 2^2S)$ oscillator strength is negative while all the other Be$^+(2^2P \rightarrow n^2L)$ $f$-values are positive. The net effect of the cancellations is a reduction in the overall size of the polarizability by a factor of five.

The Coulomb approximation polarizability [17] and the asymptotically correct wave function polarizabilities [19] achieve about 1-2% accuracy in $\alpha_1$ and $\alpha_2$. This is noticeably worse than any of the other polarizabilities listed in the Table. The older Hylleraas-type calculations by Pipin and Wozniki [18] used the variation-perturbation approach to estimate the polarizabilities (as opposed to oscillator strength sum rules). Their value of $\alpha_1 = 24.5$ [18] is compatible with the present value but not nearly as precise as the Hylleraas polarizability. The variation-perturbation calculations using the FCCI wave function [20, 21] gave polarizabilities that agree with the present Hylleraas polarizabilities to better than 0.01%.

The present results for the Be$^+(2^2P)$ state are the only results reported for the higher order polarizabilities and the hyperpolarizabilities. Previously Mérawa and Rérat reported the calculations for $\alpha_1$ and $\alpha_T^1$ for the Be$^+(2^2P)$ state using the time-dependent gauge-invariant method (TDGI) [51], but the underlying structure model for this approach is less accurate than the present calculations and we do not include their numerical values in Table VI. The overall level of agreement between the Hylleraas and HFCP calculations is very impressive when it is considered that there are significant numerical cancellations in the calculation of $\alpha_1$ that lead to a small value.
C. Effective potential for beryllium Rydberg state

Recently there have been a number of investigations of ion polarizabilities based on the interpretation of resonant excitation stark ionization spectroscopy (RESIS) [12, 14, 15, 16]. The energy splitting of adjacent Rydberg levels with \( \Delta L = 1 \) is used to determine the parent ion polarizabilities. One recent finding has been an increased appreciation of the importance of nonadiabatic and higher order polarizability terms proportional to \( r^{-7} \) and \( r^{-8} \) in the interpretation of the RESIS spectra.

Table VII summarizes all the parameters necessary to define the polarization series given by Eq. (7) for the \( \text{Be}^+ \) ion ground state. The data are presented since the neutral beryllium series represents an ideal system upon which to validate the underlying assumptions used in the analysis of the RESIS experiment. The nonadiabatic effects are strong [the nonadiabatic dipole polarizability of \( \beta_1 = -81.78175(1) \) dominates the quadrupole polarizability of \( \alpha_2 = 53.7659(2) \) in the evaluation of \( A_6 = -218.4622(1) \)] and all the “Hylleraas” polarizabilities listed in Table VII would have an overall level of precision better than 0.1%. Although no experiment has been done, a RESIS experiment upon neutral beryllium would provide a stringent test on the ability of an analysis based on Eq. (7) to extract polarizabilities from a typical RESIS spectrum.

D. The long-range dispersion coefficients

Table VIII and Table IX list the long-range dispersion coefficients for the \( \text{Be}^+ \) ion interacting with the H, He, and Li atoms. Table VIII lists dispersion coefficients when both atoms or ions are in their ground states. Table IX gives dispersion coefficients when one of the systems is in an excited state. All of the dispersion coefficients have been calculated independently using the Hylleraas and HFCP wave functions. Besides the wave functions, the procedures used to combine the lists of matrix elements were completely independent. As far as we know, the data listed in Tables VIII and Tables IX are the only dispersion coefficients published for these systems.

The level of agreement between the two sets of \( C_n \) values is generally excellent. For example, the largest difference between any of the dispersion constants listed in Table VIII is only 0.06%, occurring for the \( \text{Be}^+(2^2S)-\text{Li}(2^2S) \) value of \( C_8 \).

The high level of agreement also occurs for the \( C_n \) values listed in Table IX, the only case of a greater than 1% difference occurring for the \( \text{Be}^+(2^2P)-\text{Li}(2^2S) \) dimer. In this case, the roughly 3% disagreement occurs as a result of the previously mentioned cancellations in the oscillator strength.
sum for the $\text{Be}^+(2\,^2P)$ polarizability. The net effect of the cancellations is a reduction in the overall size of the dispersion constants by a factor of about 100. For example, the first term ($\lambda = 0$) of Eq. (52) of Tang et al. [26] was $-115.545$ while the second term ($\lambda = 2$) was $117.3969$.

We do not list dispersion coefficients for the state combinations that allow Penning or associative ionization (this occurs when the excitation energy of one atom is sufficient to cause ionization in the other atom). When this is possible, there is a singularity in the energy denominator of the oscillator strength sum rules which makes it problematic to achieve convergence.

All the values in Table VIII and Table IX provide an important benchmark for the accurate determination of the interaction potentials between $\text{Be}^+$ ion and the H, He, or Li atoms. The $\text{BeH}^+$ ion is one of the few molecular ions [3] for which a potential curve could be computed with an explicitly correlated wave function. Hence the present values for the $\text{Be}^+–\text{H}$ long-range interaction could be used to help construct a very accurate global potential surface for this system.

IV. CONCLUSION

Fully correlated Hylleraas variational wave functions have been used to determine definitive values for the oscillator strengths, polarizabilities and hyperpolarizabilities for the $\text{Be}^+$ ion $2\,^2S$ ground state and the $2\,^2P$ excited state. The Hylleraas results for the polarizabilities of the $2\,^2S$ state improve the accuracy of previous values by more than one order of magnitude. Complementary calculations using a semi-empirical method have also been done. The high level of agreement between the two calculations at the 0.1% level of precision attests to the utility of carefully formulated effective potential approaches, which can give good descriptions of atomic structure with low computational expense.

The long-range dispersion coefficients for the $\text{Be}^+$ ion interacting with a H, a He, or a Li atom have been evaluated. The polarizabilities and dispersion coefficients provide reliable references for the description of ion-atom collisions involving $\text{Be}^+$ ion and also for high precision calculations of the potential curves between the $\text{Be}^+$ ion and atoms such as H, He or Li.

In addition, all the parameters of the effective polarization potential for the $\text{Be}^+$ ion up to the $r^{-8}$ term have been obtained. These parameters are extremely useful in the description of high-$L$ Rydberg states of beryllium, and could be used in future experiments to determine the ionization potential of beryllium and also to describe the fine structure of beryllium atom Rydberg series. In addition, the present calculations lay the foundation for the further investigations of relativistic and QED effects on the polarizabilities and other properties of the $\text{Be}^+$ ion.

**Table IX:** The long-range dispersion coefficients $C_6$, and $C_8$ for the Be$^+$ ion interacting with H, He, and Li atom for the atomic states with a combined angular momentum of $L = 1$. The $M_b$ column denotes the total magnetic quantum number of the system. The first row for each system came from Hylleraas wave functions while the second row were computed with HFCP wave functions.
