Expression of steroidogenic enzymes and metabolism of steroids in COS-7 cells known as non-steroidogenic cells

Mitsuki Nozaki1, Shogo Haraguchi1,2, Takuro Miyazaki1, Daichi Shigeta1, Noriko Kano1, Xiao-Feng Lei2, Joo-ri Kim-Kaneyama2, Hiroyuki Minakata3, Akira Miyazaki2 & Kazuyoshi Tsutsui1

The COS-7 (CV-1 in Origin with SV40 genes) cells are known as non-steroidogenic cells because they are derived from kidney cells and the kidney is defined as a non-steroidogenic organ. Therefore, COS-7 cells are used for transfection experiments to analyze the actions of functional molecules including steroids. However, a preliminary study suggested that COS-7 cells metabolize [3H]testosterone to [3H]androstenedione. These results suggest that COS-7 cells are able to metabolize steroids. Therefore, the present study investigated the expression of steroidogenic enzymes and the metabolism of steroids in COS-7 cells. RT-PCR analyses demonstrated the expressions of several kinds of steroidogenic enzymes, such as cytochrome P450 side-chain cleavage enzyme, 3β-hydroxysteroid dehydrogenase/Δ4-Δ5 isomerase, cytochrome P450 7α-hydroxylase, cytochrome P450 17α-hydroxylase/17,20-lyase, 17β-hydroxysteroid dehydrogenase, 5α-reductase, cytochrome P450 21-hydroxylase, cytochrome P450 11β-hydroxylase, and cytochrome P450 aromatase in COS-7 cells. In addition, steroidogenic enzymes 3β-HSD, P450c17, P450c21, P450c11β, and 17β-HSD actively metabolized various steroids in cultured COS-7 cells. Finally, we demonstrated that 17β-HSD activity toward androstenedione formation was greater than other steroidogenic enzyme activities. Our results provide new evidence that COS-7 cells express a series of steroidogenic enzyme mRNAs and actively metabolize a variety of steroids.

The COS-7 (CV-1 in Origin with SV40 genes) cell line was developed by Prof. Yakov Gluzman in the early 1980s. It is derived from the CV-1 African green monkey kidney fibroblast cell line transformed by a mutant strain of Simian Virus 40 (SV40) that codes for the wild-type T-antigen1,2. This cell line has unique characteristics of fibroblast-like growth and virus susceptibility1,2. These characteristics make COS-7 cells a popular research tool and an excellent choice for DNA plasmid transfection experiments1–5.

Many previous studies have reported that COS-7 cells are non-steroidogenic cells6–8. The COS-7 cell line is derived from kidney cells and the kidney is defined as a non-steroidogenic organ9,10. Therefore, COS-7 cells have been used for transfection experiments to analyze the functions of steroidogenic genes11–13, steroid receptors14–16, and the effects of steroids on functional molecules17,18.

A preliminary study in our laboratory suggested that COS-7 cells actively metabolize [3H]testosterone to [3H]androstenedione (S. Haraguchi et al., unpublished observations). In addition, the expression of steroidogenic enzymes in the kidney of humans19–21 and rodents22–24 has been reported. These results suggest that COS-7 cells may metabolize steroids.

Based on this background, in the present study, a series of experiments was conducted to demonstrate the expression of steroidogenic enzymes and metabolism of steroids in COS-7 cells, which are known as non-steroidogenic cells. Because pregnenolone formation is the first step in steroid synthesis25–27, we first investigated the formation of [3H]pregnenolone from [3H]cholesterol in cultured COS-7 cells. Steroidogenic acute...
COS-7 cells express a series of steroidogenic enzyme mRNAs and actively metabolize a variety of steroids. Our results provide new evidence that COS-7 cells express a series of steroidogenic enzyme mRNAs and actively metabolize a variety of steroids.

**Materials and Methods**

**COS-7 cells.** The COS-7 cell line (JCRB9127) was purchased from the Japanese Collection of Research Bioresources (JCRB) cell bank (Osaka, Japan). COS-7 cells were maintained in DMEM (043-30085; Wako, Osaka, Japan) supplemented with 10% FBS (S1820-500; BioWest, Nuaill, France) and a 1% penicillin-streptomycin solution. COS-7 cells were used in the experiments between passages 3 and 15.

**RT-PCR analyses of steroidogenic enzyme mRNAs.** Total RNA was extracted from COS-7 cells with Sepazol-RNA I Super (Nacalai Tesque, Kyoto, Japan) and treated with RNase-free DNase I (Wako, Osaka, Japan). The total RNA samples were reverse-transcribed with M-MLV reverse transcriptase (Promega, Madison, WI, USA) according to the product instructions. All PCR amplifications (for Star, P450scc, 3β-HSDs, 5α-reductases, P450c17, P450c21, P450c11β, 17β-HSDs, and P450arom) were performed in a reaction mixture containing Ex Taq polymerase (2.5 U; Takara, Shiga, Japan). Forward and reverse primers (Table 1) were designed according to the nucleotide sequence of African green monkey steroidogenic enzyme mRNAs. The following PCR conditions were used on the thermal cycler: 1 cycle of 1 min at 94 °C, 30 cycles of 30 s at 94 °C, 30 s at 60 °C, 30 s at 72 °C, and finally, 1 cycle of 10 min at 72 °C. The identities of the PCR products were confirmed by sequencing. COS-7 cells were used in the experiments between passages 3 and 15.

**Western blot analyses of steroidogenic enzyme proteins.** Western blot analyses were performed on the proteins of COS-7 cells as described previously. The protein of COS-7 cells were separated on a 12.5% SDS-polyacrylamide gel under reducing conditions and transferred to PVDF membranes (Hybond-P; GE Healthcare, Little Chalfont, UK). The membranes were incubated with mouse anti-5α-reductase type I antibody (66329-1-lg; Proteintech, Chicago, IL, USA), rabbit anti-17β-HSD type II antibody (10978-1-AP; Proteintech), or rabbit anti-17β-HSD type IV antibody (15116-1-AP; Proteintech) at 4 °C overnight and then for 1 h with anti-mouse IgG, HRP-linked antibody (#7076; Cell Signaling Technology, Beverly, MA) diluted 1:2,000 or anti-rabbit IgG, HRP-linked antibody (#7074; Cell Signaling Technology) diluted 1:2,000. Intense immunoreactive bands were detected by using ImmunoStar Zeta detection kit (Wako). COS-7 cells were used in the experiments between passages 3 and 15.

**Biochemical analysis of cholesterol metabolism.** To investigate cholesterol metabolism, COS-7 cells were incubated with [3H]cholesterol and the radioactive metabolites were analyzed by reversed-phase HPLC.

Table 1. Primers for PCR analyses.
Biochemical analysis was performed as described previously\textsuperscript{13,25\textendash}30. In brief, COS-7 cells were plated in 10 cm\textsuperscript{2} culture dishes and grown in DMEM supplemented with 10% FBS to 90% confluence. Cells were then cultured in serum-free DMEM containing 70 nmol \([^{3}H]\)pregnenolone (specific activity, 22.9 Ci/mmol; PerkinElmer), 70 nmol \([^{3}H]\)progesterone (specific activity, 98.2 Ci/mmol; PerkinElmer), or 70 nmol \([^{3}H]\)testosterone (specific activity, 70 Ci/mmol; PerkinElmer) for 0 or 6 h at 37 \(^{\circ}\)C in a water-saturated atmosphere (5% CO\textsubscript{2}, 95% air) to maintain the pH at 7.4. After incubation, steroids were extracted with ethyl acetate and subjected to HPLC analysis using a reversed-phase column, Capcell Pak C18 MG (Shiseido, Tokyo, Japan). HPLC was performed with an isocratic condition of acetonitrile/isopropanol (60:40, vol/vol) at a flow rate of 0.3 ml/min. Eluted fractions were collected every 30 s from 0 to 30 min and counted in a liquid scintillation counter (Tri-Carb 2810TR; PerkinElmer). A reference standard of tritiated cholesterol was chromatographed to detect its elution position.

Biochemical analyses of steroids formed from pregnenolone. To investigate steroid formation from pregnenolone in COS-7 cells, conversions of substrate steroids (pregnenolone, progesterone, androstenedione, or testosterone) were measured biochemically as described previously\textsuperscript{13,25\textendash}30. In brief, at 90% confluence, COS-7 cells were cultured in serum-free DMEM containing 70 nmol \([^{3}H]\)pregnenolone (specific activity, 22.9 Ci/mmol; PerkinElmer), 70 nmol \([^{3}H]\)progesterone (specific activity, 96.6 Ci/mmol; PerkinElmer), 70 nmol \([^{3}H]\)androstenedione (specific activity, 98.2 Ci/mmol; PerkinElmer), or 70 nmol \([^{3}H]\)testosterone (specific activity, 70 Ci/mmol; PerkinElmer) for 0 or 6 h at 37 \(^{\circ}\)C in a water-saturated atmosphere (5% CO\textsubscript{2}, 95% air) to maintain the pH at 7.4. After incubation, steroids were extracted with ethyl acetate and subjected to HPLC analysis using a reversed-phase column, LiChrospher 100 RP-18 (Kanto Kagaku). Tritiated steroids \((\text{GenBank accession no. XM}_008015897)\), \(5\alpha\)-reductase type III \((\text{GenBank accession no. XM}_007998686.1)\), \(17\beta\)-HSD type VII, and P450 \(7\alpha\) were chromatographed as standards to detect their elution positions. To confirm the involvement of steroidogenic enzymes in the formation of steroids, tritiated steroids were cultured with 50 \(\mu\)M ketoconazole \((\text{Sigma-Aldrich, St. Louis, MO, USA})\), an inhibitor of cytochrome P450s 13,26,28; 50 \(\mu\)M mifepristone \((\text{GenBank accession no. XM}_007990382.1)\), and P450\(7\alpha\)-reductase. All tritiated steroids were purchased from PerkinElmer.

Quantification of steroidogenic enzyme activity. To compare the activities of steroidogenic enzymes, COS-7 cells were cultured in serum-free DMEM containing 70 nmol \([^{3}H]\)pregnenolone, 70 nmol \([^{3}H]\)progesterone, 70 nmol \([^{3}H]\)androstenedione, or 70 nmol \([^{3}H]\)testosterone for 6 h at 37 \(^{\circ}\)C in a water-saturated atmosphere (5% CO\textsubscript{2}, 95% air) to maintain the pH at 7.4. After incubation, extracted steroids were subjected to HPLC analysis using the reversed-phase column, LiChrospher 100 RP-18 (Kanto Kagaku). Tritiated steroids \((\text{GenBank accession no. XM}_007961172.1)\), \(5\alpha\)-reductase type III, P450c17, P450c21, and P450c11\(\beta\) product: cortisol; 17\(\beta\)-HSD product: androstenedione; \(5\alpha\)-dihydroprogesterone, androstenedione, testosterone, \(5\alpha\)-dihydrotestosterone, estradiol-17\(\beta\), and cortisol) were chromatographed as standards to detect their elution positions. To confirm the involvement of steroidogenic enzymes in the formation of steroids, tritiated steroids were cultured with 50 \(\mu\)M ketoconazole \((\text{Sigma-Aldrich, St. Louis, MO, USA})\), an inhibitor of cytochrome P450s 13,26,28; 50 \(\mu\)M mifepristone \((\text{GenBank accession no. XM}_007990382.1)\), and P450\(7\alpha\)-reductase. All tritiated steroids were purchased from PerkinElmer.

Results

Cholesterol does not convert to pregnenolone in COS-7 cells. To investigate the metabolism of cholesterol in COS-7 cells, RT-PCR analyses were used to detect the expression of steroidogenic and related enzymes, such as P450scC and StAR. RT-PCR analyses demonstrated the expression of P450scC mRNA, but not StAR mRNA in COS-7 cells \((\text{passages 3 to 15; Fig. 1A and Supplementary Fig. S1})\). Sequencing the amplified cDNA bands verified that it was an authentic fragment of P450scc (GenBank accession no. XM\_008015897). To investigate cholesterol metabolism, COS-7 cells \((\text{passages 3 to 15; Fig. 2A and S1})\) were incubated with \([^{3}H]\)cholesterol and the radioactive metabolites were analyzed by reversed-phase HPLC. As shown in Fig. 1B and C, no radioactive carbon was found in any of the metabolites, indicating that cholesterol does not convert to pregnenolone in COS-7 cells.

Pregnenolone is metabolized to progesterone and \(7\alpha\)-hydroxypregnenolone in COS-7 cells. To investigate the metabolism of pregnenolone in COS-7 cells, RT-PCR analyses were performed to detect the expression of steroidogenic enzymes, such as \(3\beta\)-HSD type I, \(3\beta\)-HSD type VII, and P450\(\alpha\). RT-PCR analyses demonstrated the expression of \(3\beta\)-HSD type I, \(3\beta\)-HSD type VII, and P450\(\alpha\) \((\text{passages 3 to 15; Fig. 2A and Supplementary Fig. S1})\). Sequencing the amplified cDNA bands verified that they were authentic fragments of \(3\beta\)-HSD type I \((\text{GenBank accession no. XM}_007977369.1)\), \(3\beta\)-HSD type VII \((\text{GenBank accession no. XM}_007990382.1)\), and P450\(\alpha\) \((\text{GenBank accession no. XM}_008000756.1)\).

To investigate steroid formation from pregnenolone, COS-7 cells \((\text{passages 3 to 15})\) were incubated with \([^{3}H]\)pregnenolone and the radioactive metabolites were analyzed by reversed-phase HPLC. Radioactive metabolites corresponding to \(7\alpha\)-hydroxypregnenolone and progesterone were detected \((\text{Fig. 2B,C})\). The concentration of these metabolites was reduced by treatment with ketoconazole, an inhibitor of P450s \((\text{Fig. 2B})\), and by trilostane, an inhibitor of \(3\beta\)-HSDs \((\text{Fig. 2B})\).

Progesterone is metabolized to \(5\alpha\)-dihydroprogesterone, cortisol, and androstenedione in COS-7 cells. To investigate the metabolism of progesterone in COS-7 cells, RT-PCR analyses were performed to detect the expression of steroidogenic enzymes, such as \(5\alpha\)-reductase type I, \(5\alpha\)-reductase type II, \(5\alpha\)-reductase type III, P450c17, P450c21, and P450c11\(\beta\). RT-PCR analyses demonstrated the expression of \(5\alpha\)-reductase type I, \(5\alpha\)-reductase type III, P450c17, P450c21, and P450c11\(\beta\), but not \(5\alpha\)-reductase type II \((\text{passages 3 to 15; Fig. 3A and Supplementary Fig. S1})\). Sequencing the amplified cDNA bands verified that \(5\alpha\)-reductase type I \((\text{GenBank accession no. XM}_007961172.1)\), \(5\alpha\)-reductase type III \((\text{GenBank accession no. XM}_007986861.1)\), and \(5\alpha\)-reductase type II \((\text{GenBank accession no. XM}_007990382.1)\) are expressed.
P450c17 (GenBank accession no. XM_007963991), P450c21 (GenBank accession no. XM_007973036.1), and P450c11β (GenBank accession no. XM_008001709.1) were expressed in COS-7 cells. In addition, western blot analysis demonstrated the expression of 5α-reductase type I protein in COS-7 cells (passages 3 to 15; Fig. 3B and Supplementary Fig. S2).

To investigate steroid formation from progesterone, COS-7 cells (passages 3 to 15) were incubated with [3H]progesterone and the radioactive metabolites were analyzed by reversed-phase HPLC. Radioactive metabolites corresponding to 5α-dihydroprogesterone, cortisol, and androstenedione were detected (Fig. 3C,D). The concentration of these metabolites was reduced by treatment with ketoconazole, an inhibitor of P450s (Fig. 3C), and by dutasteride, an inhibitor of 5α-reductases (Fig. 3C).

Androstenedione is metabolized to 5α-dihydrotestosterone in COS-7 cells. To investigate the metabolism of androstenedione in COS-7 cells (passages 3 to 15), RT-PCR analyses were performed to detect the expression of 17β-HSD type I and 17β-HSD type III. RT-PCR analyses demonstrated the expression of 17β-HSD type I, but not 17β-HSD type III (Fig. 4A and Supplementary Fig. S1). Sequencing the amplified cDNA band verified that it was an authentic fragment of 17β-HSD type I.

To investigate steroid formation from androstenedione, COS-7 cells (passages 3 to 15) were incubated with [3H]androstenedione and the radioactive metabolites were analyzed by reversed-phase HPLC. A radioactive metabolite corresponding to 5α-dihydrotestosterone was detected (Fig. 4B,C), but testosterone, a precursor of 5α-dihydrotestosterone, was not detected (Fig. 4B,C).

Testosterone is metabolized to androstenedione and 5α-dihydrotestosterone in COS-7 cells. To investigate the metabolism of testosterone in COS-7 cells (passages 3 to 15), RT-PCR analyses were performed to detect the expression of 17β-HSD type II, 17β-HSD type IV, and P450arom. RT-PCR analyses demonstrated the expression of 17β-HSD type II, 17β-HSD type IV, and P450arom (Fig. 5A and Supplementary Fig. S1). Sequencing the amplified CDNA bands verified that they were authentic fragments of 17β-HSD type II (GenBank accession no. XM_007994189.1), 17β-HSD type IV (GenBank accession no. XM_008014219.1), and P450arom (GenBank accession no. XM_008016613.1). In addition, western blot analysis demonstrated the expression of 17β-HSD type II and 17β-HSD type IV proteins in COS-7 cells (passages 3 to 15; Fig. 5B and Supplementary Fig. S2).
To investigate steroid formation from testosterone, COS-7 cells (passages 3 to 15) were incubated with [3H]testosterone and the radioactive metabolites were analyzed by reversed-phase HPLC. Radioactive metabolites corresponding to androstenedione and 5α-dihydrotestosterone were detected (Fig. 5C). The 5α-dihydrotestosterone peak was reduced after treatment with dutasteride, an inhibitor of 5α-reductases (Fig. 5C). Estradiol-17β, a metabolite of testosterone, was not detected (Fig. 5C).

**Identified steroidogenic pathways and comparison of steroidogenic enzyme activities in COS-7 cells.** Thus, the active steroidogenic enzymes in cultured COS-7 cells were identified as 3β-HSD, P450c11β, 5α-reductase, P450c17, P450c21, and 17β-HSD (Fig. 6). To compare the activities of steroidogenic enzymes in COS-7 cells (passages 3 to 15), we analyzed their metabolites by reversed-phase HPLC. COS-7 cells were cultured in serum-free DMEM containing 70 nmol [3H]pregnenolone, 70 nmol...
[3H]17α-hydroxyprogesterone, or 70 nmol [3H]testosterone for 6 h. After incubation, the extracted steroids were subjected to HPLC analyses to measure metabolites. The activity of 17β-HSD that metabolizes testosterone to androstenedione was significantly higher than those of other steroidogenic enzymes in COS-7 cells (Fig. 7).
To investigate the effect of molecules in FBS on steroid formation, COS-7 cells (passages 3 to 15) were cultured in 10% FBS supplemented DMEM or FBS-free DMEM to 90% confluence. At 90% confluence, COS-7 cells were cultured in serum-free DMEM containing 70 nmol [3H]pregnenolone, 70 nmol [3H]17α-hydroxyprogesterone, or 70 nmol [3H]testosterone for 6 h. After incubation, the extracted steroids were subjected to HPLC analyses to measure metabolites. The absence of FBS did not alter the activity of steroidogenic enzymes significantly in COS-7 cells (Supplementary Fig. S3).

In addition, the number of passages of the cells is an important factor for their function. Therefore, the activities of steroidogenic enzymes in cultured COS-7 cells were measured. In COS-7 cells between passages 30 and 40, the enzymatic activities of 3β-HSD and 5α-reductase were increased compared to those of COS-7 cells between passages 3 and 15 (Supplementary Fig. S4).

Discussion
COS-7 cells are derived from the kidney, which is known as a non-steroidogenic organ9,10. Therefore, COS-7 cells were also generally considered a non-steroidogenic cell line6–8. However, the present study demonstrates that COS-7 cells express a series of steroidogenic enzymes and metabolize a variety of steroids. We first demonstrated that the mRNAs of P450scc, 3β-HSDs, P4507α, P450c17, 17β-HSDs, 5α-reductases, P450c21, P450c11β, and P450arom are expressed in COS-7 cells. In addition, steroidogenic enzymes 3β-HSD, P4507α, 5α-reductase, P450c17, P450c21, P450c11β, and 17β-HSD were active in cultured COS-7 cells.

The kidney is generally considered to be a non-steroidogenic organ9,10; however, steroidogenesis in kidney tissue has been reported by some groups. Expression of P450c11β protein has been shown by western blotting and immunohistochemistry in normal human kidney19. In addition, northern blot analysis has detected 17β-HSD type XI mRNA expression in the human kidney21. In male and female rat kidneys, P450sc24 and 3β-HSDs22 mRNAs and 3β-HSD protein25 have been detected. The expression of P450sc in the rat kidney localizes to the cortical distal tubules and is high during the first days of life25,24. According to Valle et al., [14C]progesterone is...
metabolized to 5α-dihydroprogesterone, 11-deoxycorticosterone, 17α-hydroxyprogesterone, androstenedione, and testosterone in the kidney tissue, from rats of both sexes. These previous studies suggest that the kidney has the ability for local steroid production. These reports also support our findings of steroid metabolism in COS-7 cells.

In this study, we found that 5α-dihydrotestosterone, a metabolite of testosterone, was produced from androstenedione, a precursor of testosterone, in COS-7 cells. However, we could not detect a testosterone peak by reversed-phase HPLC in this system (Fig. 4B). Furthermore, testosterone was depleted from the medium after 6 h of incubation (Fig. 5B). Our results suggest that the activity of 17β-HSD type II and IV is higher than that of 17β-HSD type I in COS-7 cells (Fig. 6). In addition, a previous study has shown that the activity of 5α-reductase, an enzyme that converts testosterone into dihydrotestosterone, is high in the kidney. Furthermore, testosterone is produced in the rat kidney. These results suggest that testosterone is produced from androstenedione in COS-7 cells, but the activities of 17β-HSD type II and IV and 5α-reductase were high enough to deplete testosterone from COS-7 cell culture media. However, we could not detect estradiol-17β in cultured COS-7 cells after the

**Figure 5.** Steroid formation from testosterone in COS-7 cells. (A) RT-PCR analyses of steroidogenic enzyme 17β-HSD type II, 17β-HSD type IV, and P450arom in COS-7 cells. Total RNA was reverse-transcribed with (+) or without (−) RTase, followed by PCR amplification. (B) Western blot analyses of steroidogenic enzymes 17β-HSD type II and 17β-HSD type IV in COS-7 cells. (C) HPLC analyses of steroid formation in COS-7 cells. COS-7 cells were incubated with [3H]testosterone and the extracts were analyzed using HPLC. COS-7 cells incubated with [3H]testosterone were also treated with dutasteride, an inhibitor of 5α-reductases. The arrowheads indicate elution positions of standard steroids, testosterone (solid arrowhead), estradiol-17β (open arrowhead), androstenedione (open arrowhead), and 5α-dihydrotestosterone (open arrowhead). (D) Identified biosynthetic pathways of steroids in COS-7 cells. Black font indicates confirmed steroidogenic enzymes or pathways. Gray font indicates steroidogenic enzymes or pathways that were not confirmed. Similar results were obtained in repeated experiments using five different samples.
incubation with testosterone although P450arom are expressed in COS-7 cells (Fig. 5). It is considered that COS-7 cells may not convert androgen to estrogen. Further studies are needed to confirm this conclusion.

COS-7 cells are used for transfection experiments to analyze the function of steroidogenic genes, the function of steroid receptors, and the effects of steroids on functional molecules. However, our findings

Figure 6. Identified biosynthetic pathways of steroids in COS-7 cells. COS-7 cells express P450scc, 3β-HSDs, P450α, P450c17, 17β-HSDs, 5α-reductases, P450c21, P450c11β, and P450arom. In addition, steroidogenic enzymes 3β-HSD, P450α, 5α-reductase, P450c17, P450c21, P450c11β, and 17β-HSD were active in cultured COS-7 cells. Gray boxes indicate confirmed expression of mRNAs. White box indicates mRNAs that were not confirmed. Black arrows indicate confirmed activity of steroidogenic enzymes. White arrows indicate steroidogenic enzymes that were not confirmed.

Figure 7. Comparison of the activities of steroidogenic enzymes in COS-7 cells. The activity of steroidogenic enzymes were analyzed in COS-7 cells. COS-7 cells were cultured in serum-free DMEM containing 70 nmol [3H]pregnenolone, 70 nmol [3H]17α-hydroxyprogesterone, or 70 nmol [3H]testosterone for 6 h. After incubation, the extracted steroids were subjected to HPLC analysis to measure the metabolites (3β-HSD product: progesterone; P450c11β product: 17β-HSD product: androstenedione; 5α-reductase product: 5α-dihydrotestosterone).

incubation with testosterone although P450arom are expressed in COS-7 cells (Fig. 5). It is considered that COS-7 cells may not convert androgen to estrogen. Further studies are needed to confirm this conclusion. COS-7 cells are used for transfection experiments to analyze the function of steroidogenic genes, the function of steroid receptors, and the effects of steroids on functional molecules. However, our findings
here suggest that testosterone is actively converted to androstenedione or 5α-dihydrotestosterone in COS-7 cells. Thus, it should be noted that COS-7 cells are unfit to use for analyzing the effects of testosterone by testosterone one addition *in vitro*. Past researchers probably inferred from their experience that testosterone is inactivated in COS-7 cells. In fact, they used synthetic, non-metabolizable androgen instead of testosterone in COS-7 cells.*23*

In the present study, steroidogenic enzymes 3β-HSD, P450αα, 5α-reductase, P450c17, P450c21, P450c11β, and 17β-HSD were active in cultured COS-7 cells. However, as shown in Fig. 7, the steroidogenic enzyme activities of 3β-HSD, P450αα, 5α-reductase, P450c21, and P450c11β were low compared to the activity of 17β-HSD in cultured COS-7 cells. Thus, the activities of these enzymes might not influence the analysis of the function of steroidogenic genes. In fact, in a previous study,*26* we failed to detect enzymatic activity of P450αα in COS-7 cells. This discrepancy may be due to differences in the cell cycle stage of COS-7 cells. A future study is needed to confirm this hypothesis.
