Proapoptotic Protein Smac Mediates Apoptosis in Ovarian Cancer Cells When Treated with the Carpachromene

**Type**
Research paper

**Keywords**
Carpachromene, human ovarian cancer, Smac, caspase-3 cleavage

**Abstract**

**Introduction**
We also investigated the Carpachromene in the cytotoxicity studies against common human ovarian cancer cell line i.e., SW 626, in-vitro.

**Material and methods**
Cell viability of Carpachromene was very low against common human ovarian cancer cell line i.e. SW 626 without any cytotoxicity on normal cell line. To compare the biological activities of molecules, the enzymes used are α-glucosidase, acetylcholinesterase, respectively. Finally, calculations were made using the molecular docking method to compare the biological activity of the carpachromene molecule. We then examined whether the release of Smac is necessary for apoptosis in ovarian cancer cells using the SW 626 cell line. We first examined mitochondrial and cytosolic Smac levels after Carpachromene treatment.

**Results**
Following the docking calculations, the properties of the carpachromene molecule were examined by ADME/T analysis in order to be used as a drug in the future. In addition, the anti-oxidant properties of the molecules were examined in both gas and water phase with the HF/6-31g basis set with the Gaussian software program. As shown, exposure of ovarian cancer cells to Carpachromene decreased mitochondrial Smac and increased cytosolic Smac levels in a time-dependent fashion. As depicted in results, a decrease in Smac expression was confirmed by Western blot. Silencing of Smac significantly inhibited Carpachromene-induced caspase-3 cleavage and attenuated apoptosis in these cells. Moreover, overexpression of a Smac heptapeptide (Smac-N7) enhanced Carpachromene-induced cell death.

**Conclusions**
According to the above findings, the Carpachromene may be administrated for the treatment of several types of human ovarian cancer in humans.
Proapoptotic Protein Smac Mediates Apoptosis in Ovarian Cancer Cells When Treated with the Carpachromene

Abstract

Introduction: We also investigated the Carpachromene in the cytotoxicity studies against common human ovarian cancer cell line i.e., SW 626, in-vitro. Interestingly, we got significantly good results in the study. Also, We investigated the enzyme inhibition and molecular docking studies in this study.

Material and methods: For investigating the antioxidant properties of Carpachromene, the DPPH test was used in the presence of butylated hydroxytoluene as the positive control. Cell viability of Carpachromene was very low against common human ovarian cancer cell line i.e. SW 626 without any cytotoxicity on normal cell line. To compare the biological activities of molecules, the enzymes used are α-glucosidase, acetylcholinesterase, respectively. Finally, calculations were made using the molecular docking method to compare the biological activity of the carpachromene molecule. We then examined whether the release of Smac is necessary for apoptosis in ovarian cancer cells using the SW 626 cell line. We first examined mitochondrial and cytosolic Smac levels after Carpachromene treatment.

Results: Carpachromene inhibited half of the DPPH molecules in the concentration of 103 µg/mL. Maybe significant anti-human ovarian cancer potentials of Carpachromene against common human ovarian cancer cell lines are linked to their antioxidant activities. Following the docking calculations, the properties of the carpachromene molecule were examined by ADME/T analysis in order to be used as a drug in the future. In addition, the anti-oxidant properties of the molecules were examined in both gas and water phase with the HF/6-31g basis set with the Gaussian software program. As shown, exposure of ovarian cancer cells to Carpachromene decreased mitochondrial Smac and increased cytosolic Smac levels in a time-dependent fashion. As depicted in results, a decrease in Smac expression was confirmed by Western blot. Silencing of Smac significantly inhibited Carpachromene-induced caspase-3 cleavage and attenuated apoptosis in these cells Moreover, overexpression of a Smac heptapeptide (Smac-N7) enhanced Carpachromene-induced cell death

Conclusions: According to the above findings, the Carpachromene may be administrated for the treatment of several types of human ovarian cancer in humans.

Keywords: Carpachromene; human ovarian cancer; Smac; caspase-3 cleavage.
1. Introduction

Alpha-glucosidase inhibitors (AGIs; acarbose, miglitol, voglibose) are widely used in the treatment of patients with type 2 diabetes. AGIs delay the absorption of carbohydrates from the small intestine and thus have a lowering effect on postprandial blood glucose and insulin levels [1,2]. Acetylcholinesterase (AChE; EC 3.1.1.7) creates optimum conditions for the electron carriers by removing the chemicals that accumulate in the nerve end over time. There is no definitive treatment method for Alzheimer’s disease as in Parkinson’s disease. The current treatment methods are only aimed at minimizing the effects of the disease or improving the quality of life. For this purpose, AChE inhibitors (Donepezil, Rivastigmin) are widely used in order to ensure a better quality of life for patients [3,4].

Many recent studies have shown that when theoretical and experimental studies are carried out together, it has been observed that the study has increased quality. Both the results of the theoretical studies and the results of the experimental studies were found to be in great harmony with each other [5-8]. In the theoretical studies, both the anti-oxidant properties and biological activities of the molecule studied were examined by calculations. One of the best and common methods used to compare the biological activities of molecules is molecular docking. In order to compare the biological activities of the carpachromene molecule, calculations were made against many enzymes by molecular docking calculations [9]. As a result of these calculations, many parameters about the carpachromene molecule were obtained. The numerical values of these parameters give information about many properties of the molecule. After these calculations, ADME/T (Absorption, Distribution, Metabolism, Excretion and Toxicity) analysis was performed to examine the drug's ability to be drug. With this analysis, the potential of this molecule to be used as a drug was investigated. As a result of ADME/T analysis, many parameters were found. If the numerical values of these parameters are within certain ranges, this molecule can be used as a medicine.

Calculations were made to examine the anti-oxidant properties of the carpachromene molecule. The most important reason for examining these anti-oxidant properties is that some molecules in the human body turn into high-activity free radicals during biochemical reactions [10]. The fact that these free radicals have high activity to the cells and organs in the human body causes great damage. It causes many chronic diseases such as cancer.
and heart diseases at the beginning of these damages. By inhibiting these free radicals, this damage is desired to be minimized [11-18]. Therefore, the anti-oxidant property of this carpachromene molecule has been studied.

We also investigated the Carpachromene in the cytotoxicity studies against common human ovarian cancer cell line i.e., SW 626, in-vitro. Interestingly, we got significantly good results in the study. Also, We investigated the enzyme inhibition and molecular docking studies in this study.

2. Materials and Methods

2.1. Determination of the antioxidant activities of the Carpachromene

In this method, first pour 0.3 ml of the sample solution into a test tube, then add 9 ml of the DPPH methanolic solution. The contents of each tube were thoroughly mixed with the vortex. After 30 minutes, at room temperature and in the dark, their absorbance was read at 517 nm using a UV/Vis spectrophotometer against a methanol-containing blank. In this method, BHT was used as a positive control. According to the mentioned mechanism, the higher the antioxidant power of the sample, the yellower the color of the resulting solution will be.

The following formula was used to determine the antioxidant properties of Carpachromene [33]:

\[
\text{Inhibition (\%)} = \frac{\text{Sample A}}{\text{Control A}} \times 100
\]

Excel and Bio Data Fit 1.02: Data Fit For Biologists software were used to calculate the IC50 and to compare the antioxidant effects of these extracts with the standards and negative control and plotting [19,20].

2.2. Gene Silencing with Small Interfering RNAs and Plasmids

Small interfering RNA (siRNA) oligonucleotides were purchased from Dharmaco (Lafayette, CO) with sequences targeting Bax (5´- AACUGAUCGAAACCAUCAUGG-3´), Smac (5´-AACCCUGUGUGCGGUUCCUAAU-3´), and p53 (5´-CGG-CAUGAACCAGAGGCCCAU-3´). For Bax shRNA construction, the Bax siRNA was cloned into the pSilencer 2.1-U6 hygroplasmid. The constitutively
active Akt1 construct HA-PKB-T308D/S473D was obtained as described previously [21]. Smac and XIAP constructs were generated by RT-PCR from total RNA isolated from A2780/CP cells (cisplatin-resistant version of the A2780 cells) and cloning of the RT-PCR products into the pFLAG-CTC vector (Sigma).

2.3. Determination of anti-human ovarian cancer effects of Carpachromene

The process of the controlled culture of prokaryotic or eukaryotic cells in a filtered or unfiltered flask or cell culture plate by a suitable culture medium is called. This term is mostly used for culturing multicellular cells. Special culture media are used to culture cells. The cells are usually cultured at 37 °C in equipment such as CO₂ incubators. Cell culture should be performed under aseptic (disinfected) conditions because the growth of these cells is much slower than the growth of bacteria and yeasts and there is a possibility of contamination of the culture medium. Antibiotics such as penicillin, streptomycin, or gentamicin are sometimes used to stop the growth of bacteria. In order for cells to proliferate well in culture medium, their density in culture medium must be low. For this purpose, the cells should be passed to the fresh culture medium from time to time. One of the goals of cell culture is to study cells in terms of how they grow, their nutritional needs, and the reasons they stop growing, each of which can have a profound effect on the morphology of the cells we see under a microscope. Therefore, to study the cell growth cycle, develop methods to control the growth of cancer cells and modulate the expression of genes, it is necessary to cultivate these cells in the external environment [22-27].

With the help of cell culture, cells can be prepared that are in different stages of differentiation and can be differentiated into other cells with the help of hormones and growth factors. With the help of cell culture, homogenous cells can be prepared and intracellular activities such as DNA replication, DNA transcription synthesis, RNA and protein synthesis and other details related to metabolism can be studied. It is also possible to examine the subsequent events and intracellular currents, such as the displacement of these complexes, the type of intracellular messages, and how the messages are transmitted, after connecting different molecules to the corresponding membrane receptor. The cultured cells can be stored frozen at very low temperatures. Such conditions will maintain the growth rate or genetic composition of these cells and can be thawed and used again.
at the appropriate time. This prevents the aging of cells, while it is currently not possible to prevent the aging of animals. When working with laboratory animals, systemic changes due to the effect of the animal's natural homeostasis or the stress of the experiments on the results should be considered. While the use of cell culture eliminates this problem. In addition, standardizing laboratory tests is easier and more practical than tests on living organisms. In laboratory environments, it is much easier to control the physical and chemical factors in the living environment of cells, including acidity, heat, osmotic pressure, and the pressure of gases such as oxygen and carbon dioxide. Cells that are taken directly from the individual are known as primer cells and have a limited lifespan. Most cells have a limited lifespan, except for those taken from a tumor. An immortal cell line can proliferate indefinitely by creating a random or targeted mutation (such as artificial expression of the genus and be established as a representative of specific cell types [22-27].

In the present experiment, different human ovarian cancer cell line i.e., SW 626 cell lines and also the human normal cell line (HUVEC) were used to study the cytotoxicity and anticancer potential of human ovarian cancer over the Carpachromene using the common cytotoxicity test i.e., MTT assay in vitro condition.

The cells were cultured in medium (RPMI1640 = Roswell Park Memorial Institute1640) with 10% FBS combined with penicillin and streptomycin antibiotics in an incubator containing 5% CO₂ in a flask (T25). After three passages for purification, the cells were used to perform the next steps. Cell count and the number of viable cells were performed with a homocytometer slide using trypan blue. Evaluation of the cytotoxic effect of the Carpachromene was performed by the modified 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-2H-tetrazolium bromide (MTT) colorimetric test. In this method, MTT, which is yellow, is converted to insoluble and formazan purple dye by the dehydrogenase enzymes in the mitochondria of active cells. The adsorption of this compound can be measured after dissolving at 570-540 nm. After two days and covering the flask bottom with cell, the cell layer adhering to the flask bottom was isolated enzymatically using trypsin-EDTA (5%) (Tetraacetic acid ethylenediamine), after transfer to sterile test tubes, it was centrifuged at 2000 rpm for 10 minutes. The cells were then resuspended in a fresh culture medium with the help of a pasteur pipette and cell suspension (10⁶ ml/μg) was prepared from them. 40 μl of this cell suspension (equivalent to 10⁴×4 cells) was poured into 96-well plate flat-bottomed wells (for cell culture). Then the final volume of each well with 10% FBS medium
reached 200 μl. The first row containing cell suspension was considered as negative control (control). After incubation for 18-24 hours to remove cells from the stress caused by trypsinization, the supernatant was removed slowly and carefully, A new medium was added to all rows with different concentrations of the Carpachromene (only a new medium was added to the negative and positive control rows), so that the diluted Carpachromene with concentrations of 1-1000 μg/ml was added to the third to sixth rows, respectively, the plate was incubated in CO2 for 48, 24 and 72 hours. After the incubation time, the plate was taken out of the incubator and 20 μl of MTT (Sigma) was added to all wells, and incubated for 3 hours. The supernatant was then gently removed and 100μl of DMSO was added to the wells and pipetted to dissolve the formazan crystals. The amount of light absorption (OD) according to the intensity of the blue color of formazan at 540 nm was read by Eliza reader. To convert OD to the percentage of living cells, the following formula was used and the percentage of cell life at each concentration was calculated after 48, 24 and 72 hours [22-27].

\[
\text{Cell viability (\%) } = \frac{\text{Sample A.}}{\text{Control A.}} \times 100
\]

The concentration of the tested compounds that reduced the percentage of cell life by half was considered as IC50 (The half maximal inhibitory concentration) [22-27].

2.4. Qualitative Measurement

At least three independent replications were performed for each data and the result was presented as mean ± SD. Data statistical analysis was done with SPSS software version 22 and Anova Way One and Duncan tests. Significance was considered at the level of \( P \leq 0.05 \).

2.5. Docking study

In this study, molecular docking calculations to compare the biological activities of molecules were made using Maestro Molecular modeling platform (version 12.2) by Schrödinger. Proteins and molecules must be prepared for calculations. In the calculations, a different process is performed for the molecules at each stage. Firstly, it
was used from Gaussian software program [28] to obtain optimized structures of molecules, which created files with the extension *.sdf using these structures. Using these files, all calculations were made with Maestro Molecular modeling platform (version 12.2) by Schrödinger, LLC [29]. Maestro Molecular modeling platform (version 12.2) by Schrödinger comes together from many modules. In the first module used, the protein preparation module [30,31] was used to prepare the proteins for calculations. The crystal structures of these proteins have been downloaded from the protein data bank site. These proteins were initially minimized and water molecules in their crystal structures were removed. In the next step, the active regions of the proteins were determined for calculations, in which the proteins in this active region were given freedom of movement. Therefore, these proteins were enabled to interact with molecules more easily. In the next step, the LigPrep module [32,33] was used to prepare the working molecules for calculations.

Calculations were performed to find high energy isomers in physiological pH values of new cyanopyridine derivatives containing 3D structures and the correct protonation conditions. In the next step, the prepared protein and molecules were docked with each other. The Glide ligand docking module [34] was used for this step. The enzymes used are α-galactosidase (α-Gly) (1T0O) [35], acetylcholinesterase (4M0E) (AChE) [36-38], respectively. In this module, OPLS3e method was used in all calculations for docking calculations of molecule and proteins. The numerical value of many parameters obtained as a result of molecular docking calculations using this module is used. After the docking calculations, ADME/T analysis (absorption, distribution, metabolism, excretion and toxicity) was performed to examine the molecule's ability to be drug in the future. The Qik-prop module [39] of the Schrödinger software was used for ADME/T analysis.

- **Gaussian study**

Theoretically, the process of comparing the anti-oxidant activities of molecules requires calculating more than one thermodynamic parameter. These thermodynamic parameters are bond dissociation enthalpy (BDE), proton dissociation enthalpy (PDE), proton affinity (PA), ionization potential (IP) and electron transfer enthalpy (ETE) [40-44].
In this study, 3 mechanisms were examined in the anti-oxidant study. The first one is the hydrogen atom transfer mechanism (HAT).

\[ R + AH \rightarrow RH + A^- \quad (1) \]

In this mechanism, the free radical molecule extracts a hydrogen from the anti-oxidant and converts the anti-oxidant into its free radical form. To calculate the reactivity of the compound, it is necessary to calculate the bond dissociation enthalpy (BDE) of the A-H bond.

The second mechanism is single electron transfer-proton transfer (SET–PT). this mechanism consists of two consecutive reactions. In the first one, the removal of the electron from the AH occurs immediately after the proton transfer.

\[ R^- + AH \rightarrow R^- + AH^+ \quad (2) \]
\[ AH^+ \rightarrow H^+ + A^+ \quad (3) \]

These two mechanisms are ionization potential (IP) and proton dissociation enthalpy (PDE) from \( AH^+ \) cation radical, respectively.

The mechanism of the third and last reaction is again in two stages. these two mechanisms are called the SPLET (Sequential proton loss electron transfer) mechanism.

\[ AH \rightarrow A^- + H^+ \quad (4) \]
\[ A^- + H^+ + R \rightarrow A^- + RH \quad (5) \]

The reaction enthalpy of the first reaction is the proton affinity (PA) of the anion. The reaction enthalpy of the second reaction is abstraction of electron, namely electron transfer enthalpy (ETE). The enthalpies of the reactions for these five reactions are calculated from the formulas below.

\[ BDE = H(A^-) + H(H) - H(AH) \quad (6) \]
\[ IP = H(AH^+) + H(e^-) - H(AH) \quad (7) \]
\[ PDE = H(A^-) + H(H^+) - H(AH^+) \quad (8) \]
\[ PA = H(A^-) + H(H^+) - H(AH) \quad (9) \]
\[ ETE = H(A) + H(e^-) - H(A^-) \quad (10) \]
To calculate the numerical values in these formulas, GaussView 5.0.8, Gaussian09 AS64L-G09RevD.01 [8,45] package programs were used. Calculations of anti-oxidant molecules were calculated in Hartree-Fock (HF) [46,47] with 6-31++G(d, p) basis set in the gas and water phase.

2.6. Assessment of enzymes activities

Ellman’s method [48] was done with slight modifications of the reference. A disposable cuvette was consequently filled with 0.4 mL of 0.4 mg/mL DTNB, 25 μL of AChE solution (0.5 μkat in 1 mM acetylthiocholine), 425 μL of PBS, 50 μL of paraoxon in isopropanol or isopropanol alone [49,50]. The reaction was started by adding 100 μL of acetylthiocholine chloride in a given concentration for assessment of \(K_m\) and \(V_{\text{max}}\) or 1 mM for toxicological and pharmacological investigations. Absorbance at 412 nm was measured immediately and after one minute. Enzyme activity was calculated estimating extinction coefficient \(\varepsilon = 14,150 \text{ M}^{-1}\text{cm}^{-1}\). The inhibition effect of glucosidase of Carpachromene was assessed using Tao et al [51] process. First, the phosphate buffer (pH 7.4, 75 μL) was combined with 5 μL of the sample and 20 μL of the \(\alpha\)-glycosidase enzyme solution prepared in the phosphate buffer (0.15U/mL, pH 7.4). After pre-incubation, 50μL of p-Nitrophenyl-D glycopyranoside (p-NPG) was applied to the phosphate buffer (5mM, pH 7.4) and re-incubated at 37 °C. At 405 nm the absorbance of mixtures was reported. Three separate concentrations of Carpachromene were used to de-terminate the \(K_i\) values [52]. The graphs were then drawn from Lineweaver-Burk [53].

2. Results and Discussion

3.1. Enzymes Results

Inhibition of metabolic enzymes was investigated, and their results were reported as follows.

Carpachromene was effective inhibiting AChE as metabolic enzyme. \(K_i\) values for AChE were obtained to be 56.24±12.32 nM (Table 1). Also, the Tacrine (TAC) molecule was used as AChE enzyme control molecule; it had \(K_i\) values of 102.67±11.57 nM. Carpachromene and TAC values \(IC_{50}\) were: Carpachromene (63.87 nM, \(r^2: 0.9809\)) < TAC (123.93 nM, \(r^2: 0.9678\)) for AChE. AChE inhibitor compound is a neurotoxic molecule capable
of causing central, peripheral, or both peripheral and central cholinergic crises. The molecule investigated in the present study can record application as medicinal products developed to treat myasthenia gravis and AD.

On the other hand, carpachromene shown as IC$_{50}$ and K$_i$ values are 112.98 nM, r$^2$:0.9881 and 135.03±16.15 (Table 1). For the α-glucosidase present on cells lining, and the intestine, hydrolyzing monosaccharides are absorbed through the intestine. The results of the α-glucosidase assay showed that carpachromene has an effective α-glucosidase inhibition profile compared to that of acarbose (IC$_{50}$: 128.26 nM, K$_i$: 141.34±17.55) as a standard α-glucosidase inhibitor. The inhibition of α-glucosidase digestive enzyme was of great importance for the treatment and prevention of diabetes, postprandial glucose levels and hyperglycemia.

**Table 1.** The enzyme inhibition results of Carpachromene against acetylcholinesterase (AChE) and α-glucosidase (α-Gly) enzymes

| Compounds   | IC$_{50}$ and K$_i$ values (nM) |
|-------------|--------------------------------|
|             | AChE  | r$^2$ | α-Gly | r$^2$ | AChE  | α-Gly |
| Carpachromene| 63.87  | 0.9809| 112.98| 0.9881| 56.24±12.32| 135.03±16.15|
| Tacrine     | 123.93| 0.9678| -     | -     | 102.67±11.57| -     |
| Acarbose    | -     | -     | 128.26| 0.9013| -     | 141.34±17.55|

### 3.2. Antioxidant capacities of Carpachromene

Free radicals are molecules with a free electron ready to react, and oxygen is produced with some molecules. If many of them are suddenly produced in the body, they react with some parts of the cell, such as DNA and cell membranes, and cause cell damage or even death. Normally, the body's defense system neutralizes these harmless free radicals [52,53]. Antioxidants prevent the spread of oxidation chain reactions. Thus, the strength of an antioxidant formed by the contact of an H atom with a free radical is due to the effect of an antioxidant on the ease with which this H atom separates from it. Thus, antioxidants can protect cell membranes and various
living compounds against oxidants in small amounts. Numerous biochemical and physiological processes may cause the production of free radicals [54-56]. Reactive oxygen species (ROS) include free radicals and radical-free forms. Free radicals include hydrogen peroxide (H$_2$O$_2$), hydroxyl radical (·OH), and superoxide anion radical (O$_2^-$). When the concentration of ROS increases, it can oxidize macromolecules such as proteins, nucleic acids, and membrane lipids, resulting in cell damage and possibly "cell and tissue destruction" [47-50]. Natural compounds and molecules have two main mechanisms for reducing the concentration of ROS, in other words, natural compounds and molecules reduce the concentration of ROS by producing antioxidants and thus prevent cell damage. Recently, many researchers have paid close attention to natural compounds and molecules and their relationship to their antioxidant properties, and many natural compounds and molecules have been studied for their antioxidant activity [54-58].

Now, turning our attention to investigate the bioactivity of Carpachromene a concentration-dependent DPPH radical scavenging effect of Carpachromene was observed against BHT as a reference. DPPH process is widely applied to determine the free radical scavenging effect of different antioxidant materials. The DPPH scavenging abilities are known to be because of the hydrogen donating activities of antioxidant materials. When DPPH results are examined, it is observed that it has increased in a dose-dependent manner [27].

The interaction between Carpachromene and DPPH might have occurred by transferring electrons and hydrogen ions [54-58]. The scavenging capacity of the Carpachromene and BHT at different concentrations, expressed in terms of percentage inhibition, has been shown in Fig. 1.

In the antioxidant test, the IC50 of butylated hydroxytoluene and Carpachromene were 155 and 103 µg/mL, respectively (Table 2).

Antioxidant compounds show higher antioxidant effects against free radicals formation into the living system [59]. The antioxidant compounds have excellent redox properties and have a significant role in free radicals deactivating [60,61]. Previous researches have indicated that flavonoids and phenolic compounds have significant antioxidant properties [62,63].
**Fig. 1.** The antioxidant properties of Carpachromene (A) and BHT (B) against DPPH.

The numbers indicate the percent of free radical (DPPH) inhibition in the concentrations of 0-1000 μg/mL of Carpachromene and BHT.

**Table 2.** The IC$_{50}$ of Carpachromene and BHT in the antioxidant test.

|                | Carpachromene | BHT  |
|----------------|---------------|------|
| IC$_{50}$ (μg/mL) | 103           | 155  |
3.3. Cytotoxicity and anti-human ovarian cancer potentials of Carpachromene

Cancer is recognized as one of the leading causes of death in today's society and several drugs have been introduced to treat this disease, but, most common cancers are not yet controllable and this disease imposes huge costs on the patient and society. The main factor in the development and progression of cancer has not yet been precisely identified, however, the available data suggest that metabolic disorders in the tissue and immune disorders may be involved in the development and exacerbation of this disease [62,63]. In addition, metabolic disorders in the production and excretion of oxygen free radicals are important factors affecting cancer cells. Free radicals are destructive compounds that are produced as a by-product by the body's chemical reactions and are destroyed by the body's defense system and enzyme system and antioxidants. However, in cases where the body's metabolic disorders and the production of free radicals are high and they are not destroyed by the neutralizing system, due to their instability, these compounds have a strong tendency to react with a variety of molecules in the body [62]. It is estimated that each cell in the human body is exposed to free radicals 10,000 times a day and DNA strands 5,000 times a day. Damage to cell components includes proteins (genetic disorder), fats (lipid oxidation), and cell membranes (permeability disorder) that if the damage is not repaired, it leads to disruption of the chemical reaction and normal proteinization of the cell and the formation of harmful compounds and sometimes cancer cells in the body [63]. It is reported that thousands of cancer cells are produced daily in the human body that are killed by the body's defense system. In some cases, due to dysfunction of the above systems, cancer cells proliferate and conditions for cancer development in different tissues. According to the above, antioxidants play a vital role in preventing disorders caused by the effects of free radicals and thus the prevention and treatment of cancer. Antioxidants are a wide range of molecular compounds with complex properties that combine with and neutralize free radicals. The results show that more than 60,000 types of molecular antioxidants have been identified so far. Antioxidants can be effective in three known ways to prevent and treat cancer; 1. Destruction of free radicals 2. Strengthen the immune system to destroy cancer cells. Prevent the adhesion of cancer cells to other cells and prevent their proliferation [64-68].

In the current research, the cytotoxicity of Carpachromene was explored by studying its interaction with normal (HUVEC) and common human ovarian cancer cell line i.e. SW 626 by MTT assay for 48h. The interactions
being expressed as cell viability (%) was observed at different Carpachromene concentrations (0-1000 μg/mL) with the five cell lines which have been shown in Figures 2 and 3.

In all cases, the % cell viability gets reduced with increasing Carpachromene concentrations. The IC$_{50}$ values of Carpachromene against common human ovarian cancer cell line i.e. SW 626 cell lines were found 269, 98, 106, and 270 μg/mL, respectively (Table 3).

**Fig. 2.** The cell viability of Carpachromene against normal (HUVEC) cell line.
Fig. 3. The anti-human ovarian cancer properties (Cell viability (%)) of Carpachromene (Concentrations of 0-1000 µg/mL) against common human ovarian cancer cell line i.e. SW 626. The numbers indicate the percent of cell viability in the concentrations of 0-1000 µg/mL of Carpachromene against several human ovarian cancer cell lines.

Table 3. The IC$_{50}$ of Carpachromene in the anti-human ovarian cancer test.

|               | HUVEC | SW 626 |
|---------------|-------|--------|
| IC$_{50}$ (µg/mL) | -     | 269    |

We then examined whether the release of Smac is necessary for apoptosis in ovarian cancer cells using the SW 626 cell line. We first examined mitochondrial and cytosolic Smac levels after Carpachromene treatment. As shown, exposure of ovarian cancer cells to Carpachromene decreased mitochondrial Smac and increased cytosolic Smac levels in a time-dependent fashion. Similar results were found for cyt c release. The release of
Smac or cyt c in apoptosis was also consistently shown by immunostaining. To further study the role of Smac in cell apoptosis, we used siRNA to knockdown Smac expression. As depicted in Fig. 4A, a decrease in Smac expression was confirmed by Western blot. Silencing of Smac significantly inhibited Carpachromene-induced caspase-3 cleavage and attenuated apoptosis in these cells (Fig. 4A). Moreover, overexpression of a Smac heptapeptide (Smac-N7) enhanced Carpachromene-induced cell death (Fig. 4B). These results suggest that Smac, the mitochondrial apoptogenic protein, plays a prominent role in the execution of Carpachromene-induced apoptosis in ovarian cancer cells.
FIGURE 4. Smac plays an important role in Carpachromene-induced apoptosis. A, cells were transfected with Smac or control (Ctrl) vector siRNA for 48 h and then treated with Carpachromene for 24 h. Cell apoptosis was quantitatively detected by a cell death ELISA kit as described under “Experimental Procedures.” Graphs showing results of quantitative analyses. B, cells were pretreated with Smac-N7 or control (15 mM) peptide for 3
h, followed by treatment with or without Carpachromene for 24 h. Apoptosis was measured by a cell death ELISA kit as described under “Experimental Procedures.”

2.4. Docking results

Biological activities and anti-oxidant properties of molecules can be examined by using theoretical calculations. These calculations are an important guide for synthesizing molecules with higher activity.

As a result of molecular docking calculations of the molecule, many parameters were obtained. Each parameter obtained gives information about many different properties of the molecule. The most important parameter among these parameters is Docking Score, because the numerical value of this parameter is the most important indicator of interaction between molecule and enzyme [69-71]. The molecule with the lowest numerical value of this parameter has the highest biological activity. The molecule with the highest biological activity is the molecule that interacts most with the enzyme. These interactions have many interactions such as hydrogen bonds, polar and hydrophobic interactions, π-π and halogen [72-78]. The parameters obtained from the interaction between the molecule and the enzyme are given in Table 4 and the representation of these interactions is given in Figures 4 and 5.

| Table 4. Numerical values of the docking parameters of molecule against enzymes |
|-----------------------------------------------|----|----------|
| Docking Score                                | AChE | α-Glucosidase |
| Glide ligand efficiency                      | -6.92 | -4.28 |
| Glide hbond                                  | -0.28 | -0.17 |
| Glide evdw                                    | 0.00  | -0.17 |
| Glide evdw                                    | -35.62 | -25.95 |
| Glide ecoul                                  | -0.39  | -4.56 |
| Glide emodel                                 | -56.03 | -43.68 |
| Glide energy                                 | -36.01 | -30.50 |
Another parameter obtained from the calculations is Glide ligand efficiency, the numerical value of this parameter gives information about the activity of the molecules studied. The parameters showing the numerical values of the interaction between the molecule and the enzyme are Glide hbond, Glide evdw, Glide ecoul. On the other hand, Glide emodel, Glide energy, Glide einternal, and Glide posenum parameters are the numerical values of the exposure formed between the molecule and the enzyme [79].

![Diagram 1](figure1.png)

**Figure 4.** Presentation interactions of carpachromene with α-Glucosidase enzyme

![Diagram 2](figure2.png)

**Figure 5.** Presentation interactions of carpachromene with AChE enzyme
Another parameter obtained from the calculations is Glide ligand efficiency, the numerical value of this parameter gives information about the activity of the molecules studied. The parameters showing the numerical values of the interaction between the molecule and the enzyme are Glide hbond, Glide evdw, Glide ecut. On the other hand, Glide emodel, Glide energy, Glide einternal, and Glide posenum parameters are the numerical values of the exposure formed between the molecule and the enzyme [80].

Following molecular docking calculations, ADME/T analysis was performed to examine the drug-making properties of the carpachromene molecule. ADME/T analysis examines the effects and reactions of drug molecules on human metabolism. As a result of the ADME/T analysis, many parameters were obtained. With this analysis, Absorption, Distribution, Metabolism, Excretion and Toxicity movements of molecules in human metabolism are predicted [8]. The parameters obtained from this analysis of the carpachromene molecule are given in Table 5.

| Parameter          | Carpachromene | Reference Range |
|--------------------|---------------|-----------------|
| mol_MW             | 336           | 130-725         |
| dipole (D)         | 5.55          | 1.0-12.5        |
| SASA               | 606           | 300-1000        |
| FOSA               | 149           | 0-750           |
| FISA               | 138           | 7-330           |
| PISA               | 319           | 0-450           |
| WPSA               | 0             | 0-175           |
| volume (A³)        | 1049          | 500-2000        |
| donorHB            | 1             | 0-6             |
| acceptHB           | 3.75          | 2.0-20.0        |
| glob (Sphere =1)   | 0.82          | 0.75-0.95       |

Table 5. ADME properties of molecule
| Parameter                | Value 1 | Value 2  | Value 3  |
|--------------------------|---------|----------|----------|
| QPpolrz (Å³)             | 37.60   | 13.0-70.0|          |
| QPlogPC16                | 11.38   | 4.0-18.0 |          |
| QPlogPoct                | 16.43   | 8.0-35.0 |          |

| QPlogS                   | -5.62   | -6.5-0.5 |          |
| CIQPlogS                 | -5.68   | -6.5-0.5 |          |
| QPlogHERG                | -5.89   | (concern below -5) |          |
| QPPCaco (nm/sec)         | 488     | *        |          |
| QPlogBB                  | -0.91   | -3.0-1.2 |          |
| QPPMDCK (nm/sec)         | 228     | *        |          |
| QPlogKp                  | -2.75   | Kp in cm/hr |          |
| IP (eV)                  | 9.28    | 7.9-10.5 |          |
| EA (eV)                  | 0.65    | -0.9-1.7 |          |
| #metab                   | 2       | 1-8      |          |
| QPlogKhsa                | 0.66    | -1.5-1.5 |          |
| Human Oral Absorption    | 3       | -        |          |
| Percent Human Oral Absorption | 97 | **    |          |
| PSA                      | 85      | 7-200    |          |
| RuleOfFive               | 0       | Maximum is 4 |          |
| RuleOfThree              | 0       | Maximum is 3 |          |
| Jm                       | 0.00    | -        |          |

* <25 is poor and >500 is great, ** <25% is poor and >80% is high.

In the ADME/T analysis, the first parameter is mol_MW, which shows the numerical value of the mol mass of the molecule. Another parameter is SASA, which is π (carbon and attached hydrogen) component of the SASA.
Another parameter is WPSA, which is weakly polar component of the SASA (halogens, P, and S). Another parameter is QPlogPo/w, which is predicted octanol/water partition coefficient. Another parameter is CIQPlogS, which is Conformation-independent predicted aqueous solubility, log S. S in mol.dm$^{-3}$ is the concentration of the solute in a saturated solution that is in equilibrium with the crystalline solid. Another parameter is QPlogHERG, which is the numerical value of the estimated IC50 value when the HERG K channels are blocked. Another parameter is QPPCaco, which is Caco-2 cell permeability in the gut-blood barrier for inactive transport. Another parameter is QPlogBB, which is the estimated brain/blood division coefficient. The numerical value of this parameter is for orally administered drugs, therefore, for example, dopamine and serotonin CNS are negative because they are molecules that are too polar to cross the blood-brain barrier. Another parameter is #metab, which is number of likely metabolic reactions. Another parameter is PSA, which is Van der Waals surface area of polar nitrogen and oxygen atoms [81].

The two most important parameters among all ADME/T parameters are RuleOfFive and RuleOfThree. The RuleOfFive [82] and RuleOfThree [83] parameters are more important than any other parameter. The numerical value of these two parameters is expected to be zero. The RuleOfFive parameter is also the fifth rule of Lipinski's Pfizer. The rules are: mol MW <500, QPlogP o/w <5, donorHB ≤ 5, acceptHB ≤ 10. However, the RuleOfThree parameter is known as the three of Jorgensen’s rule. The three rules are: QPlogS> -5.7, QP PCaco> 22 nm/s, #Primary Metabolites <7. If the numerical value of the RuleOfThree parameter is zero, this molecule can be used orally as a medicine. The last and another important parameter is Jm, which is predicted maximum transdermal transport rate, Kp×MW×S (μg.cm$^{-2}$.hr$^{-1}$). Kp and S are obtained from the aqueous solubility and skin permeability, QPlogKp and QPlogS. The theoretical estimate obtained by applying molecules that can be drugs with this parameter to the skin are numerical values (Table 6) [83].

|       | BDE   | IP    | PDE   | PA    | ETE   |
|-------|-------|-------|-------|-------|-------|
| O8-H  | 53.15 | 147.89| 219.76| 288.67| 78.98 |
| O24-H | 40.18 | 147.89| 206.78| 284.45| 70.22 |
For the anti-oxidant calculations of the molecule, it was done by removing hydrogen from the OH bond in the molecule. The carpachromene molecule has 2 OH bonds, one is oxygen atom 24 and the other is oxygen atom 8. The numerical value of BDE for the OH bond of the carpachromene molecule is a parameter related to the HAT mechanism. The molecule with the numerical value of the smaller BDE parameter was found to have higher radical-scavenging activity.

In the first step of the SET – PT mechanism, the IP value of the carpachromene molecule is calculated. If a molecule has a lower IP value, it is known that the molecule has a higher ability to give electrons. In the second step of the SET – PT mechanism, PDE values are calculated. If a molecule has a lower PDE value, this means an easier reaction. Finally, the SPLET mechanism consists of two stages. In the first stage, PA parameter is calculated. If a molecule has a lower PA value, it indicates that the molecule has a higher proton affinity. In the second stage of SPLET, the ETE parameter is calculated. If a molecule has a lower ETE value, that molecule indicates an easier reaction [82,83].

The parameters of all calculated anti-oxidant properties are given in Table 6. The parameters given in this table are calculated both in gas phase and water phase. In the calculations made, it was made for two O-H bonds, but different positions were more active in both phases. The main reason for this is that the solvent affects the stability of the formed phenolate anion [83].

|        | in water phase |
|--------|---------------|
|        | O8-H          | 51.93 | 113.52 | 252.91 | 301.81 | 64.63 |
|        | O24-H         | 93.21 | 113.52 | 294.19 | 297.59 | 110.12 |
As a result of the calculations made, Spin densities were calculated to examine the charge density of the molecules. Spin density values of the molecule are given above the atoms in Figure 6. The lower spin density shown on the atoms in the molecule indicates greater delocalization. Consequently, higher delocalization means easier radical formation. Being more radical as a result of all these situations affects the stability of the radical and causes the formation of more stable radicals.

**Conclusions**

Biological activities of carpachromene molecule against many enzymes were compared in molecular docking and anti-oxidant properties. Many parameters were obtained for the biological activity of the carpachromene molecule against enzymes. Afterwards, ADME/T analysis of this molecule was done. The ability of the carpachromene molecule to be used as a drug in the future was examined. These studies will be a great guide for future in vivo and in vitro studies. Finally, the anti-oxidant properties of the carpachromene molecule were examined. Necessary parameters for radical activity were collected.
Carpachromene was also assessed in biological applications like radical scavenging, cytotoxicity, and anticancer (adenocarcinoma) activities. Carpachromene exhibited good antioxidant properties, even better than the reference standard molecule. It also showed significant cytotoxic activities against common human ovarian cancer cell line i.e., SW 626 cell lines.

Conflicts of Interest

There isn’t any conflict of Interest.
