Abstract

Introduction: Insufficient knowledge about endometriosis among women is one of the causes of its delayed diagnoses. Due to the exceptional trickiness of symptoms, the most important part is played by proper and exhaustive knowledge, allowing its early detection. The objective of the study was to assess Polish women's awareness of endometriosis.

Methods: The pilot studies were performed with the participation of 200 women, in an average age of M=33.65 years (SD = 11.45), who filled in the authors’ questionnaire related to self-assessment of the level of knowledge about the disease, its symptoms, late effects and directions of a remediation procedure. The statistical analysis was performed using the IBM SPSS Statistics 25 suite. It included a frequency analysis, a one-way analysis of variance ANOVA, a single variable regression analysis and Student’s t-test for independent samples.

Results: Almost 84% of women had heard about endometriosis, while only 1/3 of them considered their knowledge sufficient or good. Very good knowledge was declared by 4.5% of women, and 16.1% had never heard about it. The knowledge level turned out significantly higher (p = 0.001) among women with medical education. Polish women acquired their knowledge mainly from the Internet and the experience of other women. They see reasons behind their lack of knowledge in the still existing ‘taboo’ related to menstruation, the absence of information in the media and education in schools, which is critical according to 92.4% women.

Conclusions: Polish women's level of knowledge about endometriosis is insufficient, which should be changed. Higher awareness is presented by women with medical education, and the higher the level of knowledge, the larger the interest of women in healthy behaviour.

Introduction

Endometriosis is a mild form of the disease of female reproductive organs. It is a chronic, oestrogen-related inflammatory disease characterised by the presence of the endometrium beyond the uterine cavity\textsuperscript{1,2,3}. It is an exceptionally heterogeneous disease, which can cause minor symptoms among some women, and an agonising pain among others, which affects their professional life, social contacts or reproduction\textsuperscript{4,5,6}. Also, the growing intensity of symptoms is often not correlated with the severity of the disease\textsuperscript{5–8}. One of its most troublesome symptoms is the overwhelming pain, which can occur as nonmenstrual pain in the lesser pelvis (10%-50%), cyclic pain during menstruation (28%-80%), pain during sexual intercourse (12%-40%) or defecation\textsuperscript{1,3,6–11}. Over time, the disease leads to infertility, which affects 30%-50% of women\textsuperscript{2,4,7,12}. These symptoms affect the physical and emotional well-being of women, seriously disrupting the quality of their lives\textsuperscript{13,14,15}.

It is assumed that endometriosis affects approximately 10%-15% of the population of women of childbearing age, which amounts to 176 million of women in the whole world\textsuperscript{3,7,9,11}. Most data on this
subject originates from American, British, Canadian and Australian epidemiological research\textsuperscript{1,5,8,10,15−18}. So far, no wide research has been performed for the area of Poland. In the Ministry of Health’s statistics for 2018, there are only 14,000 women with endometriosis who have been treated in a hospital (3,560 women) or an outpatient clinic (10,461 women)\textsuperscript{19}. However, it is discussed unofficially that in Poland the number may be as high as 2 million women\textsuperscript{20}.

Due to the heterogeneity of symptoms, endometriosis is diagnosed with much delay. In the world, the average time of waiting for a proper diagnosis is currently 8–10 years, depending on the country\textsuperscript{3,4,8,10,14,18,21,22}. Reasons for this are sought in ignoring its early symptoms, especially those related to menstrual pain\textsuperscript{4,8−11}. For centuries, the menstrual pain was a taboo, an embarrassing problem and an element of a woman’s life. There is still a popular opinion that it is a kind of women’s ‘thing’ which does not require the implementation of diagnostics\textsuperscript{16,19}, and women who complain are perceived as exaggerating the symptoms, or suffering from diseases of a psychosomatic nature\textsuperscript{3,23−26}. On the other hand, in accordance with the recommendations of the European Society of Human Reproduction and Embryology (ESHRE), in each case of the occurrence of ailments related to the menstrual cycle, after the exclusion of their other causes, endometriosis is to be suspected\textsuperscript{2,27}.

Endometriosis is also a costly problem of public health. The average annual cost of treatment per one patient was calculated in 10 countries at € 9,579. These costs result mainly from surgeries, monitoring examinations, hospitalisation, as well as medical visits, and they grow along with the increasing intensity of endometriosis\textsuperscript{1,8,13,21,28}.

All over the world, actions are taken in order to build social awareness of endometriosis by various social campaigns and actions of the associations of sick women\textsuperscript{32}. Since 2014, worldwide EndoMarches have been organised in March, the month of building this awareness, uniting over 60 countries in the world under one common objective: to eliminate the taboo and replace it with dialogue\textsuperscript{29}. In 2019, for the first time Polish women also joined the rest of the world, believing that this march can be a good beginning of a change in the approach to women with endometriosis, including in Poland\textsuperscript{20}.

Due to the scale of the problem, it is becoming a priority to increase social awareness about endometriosis. In the literature, there is available data related to the awareness of other diseases, but there are few papers related to the knowledge about endometriosis in the world, with the total absence of them in relation to Poland\textsuperscript{30–32}. Seeing an enormous need for changes in this regard, the authors of the present paper committed themselves to assessing women’s level of knowledge about endometriosis.

**Method**

The pilot studies were performed with the participation of 232 women who were more than 18 years of age. The final analysis took into account 200 individuals; 32 surveys were incomplete. Due to the lack of
a standardised questionnaire, the research tool consisted of the authors’ own survey, created based on the review of the related literature\textsuperscript{33}.

The research was performed upon an approval of the ethical commission for scientific research of the WSB University in Dąbrowa Górnicza, no. AWSB/KE/02/2020. Informed consent was obtained from all participants. All methods were carried out in accordance with relevant guidelines and regulations.

The questionnaire was preliminarily tested among 10 people and subsequently, after making the necessary corrections, formatted for the needs of an internet poll and uploaded to the generally available Google Forms Platform, where it was accessible for filling up during a period from 10 June 2020 till 30 September 2020. In order to acquire a sample of the target population, the recruitment of participants proceeded by publishing a link to the questionnaire in a social medium (Facebook). Before collecting the data of the respondents, they were informed about the voluntariness and anonymity of participation in the research. It took about 15–20 minutes to complete the Internet poll.

The survey was divided into two parts. The first one involved sociodemographic variables of the participants (age, sex, level and direction of education, occupation and professional status, place of residence). In the second part of the poll, there were 45 questions which had a closed-ended nature, and they provided a possibility to choose one or several answers among the listed options. The questions referred to self-assessment of the level of knowledge about endometriosis, as well as the sources of this knowledge, reasons behind possible lack of knowledge, the age of women who are mainly affected by this disease, the time necessary to make a proper diagnosis, first atypical symptoms and effects of the disease, as well as a need for education in that regard, its forms and benefits provided by it to women.

The criterion of inclusion into the research consisted of a female gender, an age above 18 years and filling up the complete questionnaire, while a male gender, an age below 18 years or an incomplete questionnaire meant exclusion from the research. All methods were carried out in accordance with relevant guidelines and regulations.

In order to provide answers to the presented research questions, statistical analyses were performed using the IBM SPSS Statistics 25 suite. It enabled the performance of a frequency analysis, a one-way analysis of variance ANOVA, a single variable regression analysis and Student’s \textit{t}-test for independent samples. In order to determine the relations, an analysis was performed based on cross tabulation and a chi-squared test of independence. The significance level adopted in the present chapter was $\alpha = 0.05$.

### Results

The highest number of respondents had higher education (48.5\%) and lived in urban areas (79\%). 76\% of women were professionally active; 43.5\% of respondents pursued a medical profession (Table 1).
Table 1
Sociodemographic characteristics and the level of knowledge about endometriosis of the surveyed women (n = 200).

| VARIABLES                                      | n  | %   |
|------------------------------------------------|----|-----|
| **Education level**                            |    |     |
| full secondary                                 | 48 | 24  |
| incomplete higher (bachelor's degree)          | 31 | 15.5|
| higher                                         | 97 | 48.5|
| none - student                                 | 26 | 13  |

| suburban areas                                 | 10 | 5   |
| village                                        | 32 | 16  |
| **Degree of knowledge about endometriosis:**   |    |     |
| very good                                      | 9  | 4.5 |
| good                                           | 55 | 27.5|
| sufficient                                     | 61 | 30.5|
| satisfactory                                   | 18 | 9   |
| insufficient                                   | 26 | 13  |
| very bad                                       | 31 | 1.5 |
| **Sources of knowledge**                       |    |     |

*The number n does not equal 200, due to the possibility of giving more than one answer
An analysis of the frequency of answers to questions from the poll related to the knowledge of women about endometriosis indicated that most of the surveyed women (83.9%) knew what endometriosis is, while in terms of self-assessment of the level of their knowledge, the most women stated that it was sufficient or good. On the other hand, the lowest number declared very good or satisfactory knowledge. In turn, 16.1% of respondents had never heard about the disease.

Most women acquired their knowledge about the disease from the Internet (45%), less from the experience of other women (36.1%), and the lowest number got it from their own experience (15.3%). The women see the reasons behind the lack of knowledge primarily in an insufficient amount of information on this subject in the media (64%), the belief that menstrual pain is a standard attributed to the gender and not a disease symptom (53.5%), and the widespread ‘taboo’ related to menstruation (66%) (Table 2).
Table 2
Knowledge about endometriosis depending on medical and nonmedical education

|                  | Medical (n = 87) | Nonmedical (n = 113) | 95% CI |
|------------------|------------------|----------------------|--------|
|                  | M                | SD                   | M      | SD   | t    | p      | LL    | UL    | Cohen's d |
| Knowledge about endometriosis | 3.63             | 1.31                 | 2.85   | 1.40 | 4.02 | 0.001  | 0.40   | 1.17  | 0.58     |

Women's lack of knowledge involved the fact that diagnosing the disease requires a period of many years (83.2%), the possibility of the occurrence of infertility as a consequence of the untreated disease (72.5%), or finally that the disease primarily affects women in the period of full reproductive maturity (21.3%) (Table 1).

Among women with medical education, knowledge about the disease turned out to be statistically significantly higher (p = 0.001) than among women lacking such education (Table 2). On the other hand, neither the age nor the place of residence were predictors of knowledge about endometriosis - this relationship turned out to be statistically insignificant (Table 3).

Table 3
Age as the predictor of knowledge about endometriosis

|                | B     | SE    | Beta  | t     | R²    | F     |
|----------------|-------|-------|-------|-------|-------|-------|
| (constant)     | 3.17  | 0.31  | 10.17 | 0.001*** | 0.01** |       |
| Age            | 0.001*** | 0.01** | 0.001*** | 0.03* |       |       |

* - p < 0.05; ** - p < 0.01; *** - p < 0.001

Place of residence as the predictor of knowledge about endometriosis

|                | Town (n = 158) | Suburban areas (n = 10) | Village (n = 29) | M     | SD    | M     | SD    | F     | p     | η² |
|----------------|----------------|-------------------------|------------------|-------|-------|-------|-------|-------|-------|----|
| Knowledge about endometriosis | 3.22             | 1.35                 | 2.50             | 1.78  | 3.21  | 1.54  | 1.23  | 0.295 | 0.01  |

The approach of the surveyed women to menstrual pain was also analysed. It turned out that 85% of them believe it to be an abnormal symptom, while the remaining ones consider it a standard. An analysis of relations was performed for women who admitted that they experience strong menstrual pains, and
had a varying approach to the normality of their occurrence. However, it turned out to be statistically insignificant (Table 4). 66.5% of women also admitted that menstruation is still a ‘taboo’ in Poland. Therefore, the relationship between the approach to menstrual pain and the consideration of menstruation as a taboo was also analysed. In this regard, the analysis did not exhibit statistical significance either (Table 4).

### Table 4
Relationships between the occurrence of menstrual pain and normality of the course of menstruation/a taboo subject.

#### Relationship between the occurrence of painful menstruation and consideration of this pain as a normal process

| The occurrence of painful menstruation | Continuous  | Continuous  | Total |
|---------------------------------------|-------------|-------------|-------|
|                                        | continuous  | abnormal    |       |
| continuous  | normal       |            |       |
| No         | 22           | 73.3%       | 135   | 67.5% |
| Yes        | 8            | 26.7%       | 65    | 32.5% |
| Total      | 30           | 100%        | 170   | 100% |

\[\chi^2(1) = 0.55; p = 0.303\]

#### Relationship between considering menstrual pains normal or not and menstruation itself as a taboo

| Menstruation is still a ‘taboo’ in Poland | Continuous  | Continuous  | Total |
|------------------------------------------|-------------|-------------|-------|
|                                        | normal      | abnormal    |       |
| continuous  | menstrual pains - normal                |            |       |
| No         | 9            | 30%         | 67    | 33.5% |
| Yes        | 21           | 70%         | 133   | 66.5% |
| Total      | 30           | 100%        | 170   | 100% |

\[\chi^2(1) = 0.19; p = 0.415\]

32.5% of the surveyed women experiencing strong menstrual pains admitted that they had accepted and ignored them so far, mainly due to shame, embarrassment and fear of ridicule during possible reporting of such concerns to a physician (Table 5). As many as 90.5% claimed that such an approach towards menstruation should change. 92.4% of women also think that education about endometriosis is necessary, and that it could result in a number of benefits (Table 5). They also believe that, since menstrual pains experienced already by young girls are the first symptom which can indicate the
presence of the disease, then education in that regard should be primarily handled by schools, followed by the media and physicians (Table 5).

### Table 5
Reasons behind the acceptance of menstrual pain, benefits from education and its indicated sources

| Reasons behind the acceptance and ignorance of menstrual pain | %     |
|-------------------------------------------------------------|------|
| shame                                                       | 53.3 |
| embarrassment                                               | 49.2 |
| fear of ridicule                                            | 68.3 |
| Benefits resulting from education about endometriosis       |      |
| more careful observation of signals sent by one’s own body  | 83.7 |
| consultation of one’s concerning symptoms with a physician  | 68.8 |
| prevention of the deteriorating quality of life for women suffering from the pain | 60.4 |
| decreasing the percentage of women with infertility        | 54.5 |
| increasing the awareness that it is a disease, not an inherent feature of women | 23.2 |
| Indicated sources of education                              |      |
| school                                                      | 83.2 |
| media                                                       | 63.9 |
| physicians                                                 | 53.5 |

### Discussion

Endometriosis is a disease with an increasing frequency of occurrence in the populations of all countries in the world. Its early diagnosis gives women a chance to return to normal everyday functioning without pain. The lack of knowledge about its symptoms and effects, and thus their frequent ignorance, delays visits to medical specialists, and therefore prolongs the making of a proper diagnosis and the initiation of treatment.

The authors’ own research results indicated that, although most women declared that they had heard about the existence of endometriosis, their knowledge in this regard is definitely inefficient, and 16.1% of them lack it entirely. In the research of Moradi M. et al., covering 35 women suffering from endometriosis, many of them had never heard about this disease before being diagnosed either. On the other hand,
52% of those surveyed by Shadbolt et al. had heard about the existence of endometriosis\(^{33}\). Similar observations were made by Bush D. et al. while performing research in New Zealand in 2015, where 32% of students from Canterbury and 18% in Hawkes Bay were aware of its existence\(^{27}\).

In our research, a higher level of knowledge was demonstrated by women with medical education, while neither the age nor the place of residence were predictors of knowledge about endometriosis. Among women who claimed that they had heard about the disease, most of them had learned about it from the Internet, or from other women suffering from it. Only some of them acquired this knowledge from a physician. Similar answers were provided by women surveyed in the paper of Facchin F. et al., who, due to unpleasant contacts and relations with physicians, would rather use the Internet to acquire information about the disease\(^{23}\).

Women with endometriosis, especially with pain symptoms present during menstruation, face a social stigma and a wide range of various reactions of physicians when looking for medical help in that regard. Consideration of the symptoms of endometriosis as ‘a part of the normal life of women’ seems to be an experience shared by women with endometriosis all over the world. This is mentioned in the papers of Grundström H., Moradi M. et al.\(^{21}\), Culley L. et al.\(^{18}\), as well as Riazi H. et al.\(^{34}\) Grundström H. et al.\(^{4}\), as well as Facchin F. et al.\(^{23}\) pointed out that women reporting to physicians due to menstrual pain were facing the lack of knowledge, empathy or support, and they were treated by the medical personnel with ignorance and incredulity. The women felt embarrassed when they were describing to the physicians how the pain and bleeding were limiting and controlling their everyday lives. In the authors’ own research, 32.5% of women experiencing their own strong menstrual pains also ignored the problem, mainly due to fear of ridicule, shame and embarrassment.

Infertility turned out to be the most concerning consequence of the untreated disease both among those women who declared at least sufficient knowledge about the disease, as well as those who lacked this knowledge. Navarria-Forney, I. et al. also showed that most women (96%) were worried about the impact of endometriosis on fertility. Importantly, most of them considered themselves insufficiently informed about the possibilities of maintaining fertility\(^{35}\).

Almost all of the surveyed women (92.4%) were also interested in extending their knowledge about the disease. They indicated that education should be handled primarily by schools, followed by the media and physicians. In the papers of Shadbolt et al., the necessity of education, especially among teenagers, is expressed by as many as 89% of the surveyed women, while any health-promoting actions should be directed towards sources preferred especially by young women: schools (40%), the Internet (22%) and magazines (13%). Through education, the participants in the studies would like to learn about the symptoms, risk factors and treatment of the disease, similarly to the respondents from our research\(^{32}\). The key significance of education on menstrual pain experienced by teenage women was also described by DiVasta A.D. et al., who claimed that the promotion of proper behaviour could be related to care and a decrease in the delays of endometriosis diagnostics\(^{11}\).
There is also strong suggestive evidence that a consistently managed programme of education on menstrual health in schools increases the awareness of teenage girls about endometriosis. This was proven by researchers from New Zealand, who ran an audit of education programmes related to menstrual health and endometriosis introduced in secondary schools, and conducted observations regarding the number of young women reporting to physicians for this reason. It turned out that in the region in which the educational programme was consistently pursued, the awareness of girls regarding endometriosis was 32%. Moreover, a shift was also observed in terms of young women's earlier contacts with specialised health care. A similar opinion was expressed by respondents in the papers of Hudelist G. et al. and Moradi M. et al.

An outline of a remediation programme should be created based on the yielded research results, the priority of which will be to decrease the number of cases of endometriosis in Poland, or at least its effective diagnosing and treatment.

**Conclusions**

Polish women's level of knowledge about endometriosis is insufficient, but higher among women with medical education. Furthermore, it has been concluded that the higher the level of knowledge, the larger the signs and interest of women in healthy behaviour. The indication of symptoms and effects of the untreated disease turned out to be a sufficient reason to convince women to consult a physician in a situation of having them personally. The research will continue with a larger target group, since there is a need for wide investigation of the subject and education in that regard.
