Abstract

We study the S-wave interaction of mesons with baryons in the strangeness $S = 0$ sector in a coupled channel unitary approach. The basic dynamics is drawn from the lowest order meson baryon chiral Lagrangians. Small modifications inspired by models with explicit vector meson exchange in the $t$–channel are also considered. In addition the $\pi\pi N$ channel is included and shown to have an important repercussion in the results, particularly in the $I = 3/2$ sector. The $N^*(1535)$ resonance is dynamically generated and appears as a pole in the second Riemann sheet with its mass, width and branching ratios in fair agreement with experiment. A $\Delta(1620)$ resonance also appears as a pole at the right position although with a very large width, coming essentially from the coupling to the $\pi\pi N$ channel, in qualitative agreement with experiment.

1 Introduction

The introduction of effective chiral Lagrangians to account for the basic symmetries of QCD and its application through $\chi PT$ to the study of meson meson interaction [1] or meson baryon interaction [2, 3, 4, 5] has brought new light into these problems and allowed a systematic approach. Yet, $\chi PT$ is constrained to the low energy region, where it has had a remarkable success, but makes unaffordable the study of the intermediate energy region where resonances appear. In recent years, however, the combination of the information of the chiral Lagrangians, together with the use of nonperturbative schemes, have allowed one to make prediction beyond those of the chiral perturbation expansion. The main idea that has allowed the extension of $\chi PT$ to higher energies is the inclusion of unitarity in coupled channels. Within the framework of chiral dynamics, the combination of unitarity in coupled channels together with a reordering of the chiral expansion, provides a faster convergence and a larger convergence radius of a new chiral expansion, such that the lowest energy resonances are generated within those schemes. A pioneering work along this direction was made in [6, 7, 8] where the Lippmann Schwinger equation in coupled channels was used to deal with the meson baryon interaction in the region of the $N^*(1535)$ and $\Lambda(1405)$ resonances. Similar lines, using the Bethe Salpeter equation in the meson meson interaction, were followed in [9] and a more elaborated framework was subsequently developed using the Inverse amplitude method (IAM) [10] and the N/D method [11]. The IAM method was also extended

*e-mail: inoue@ific.uv.es
to the case of the meson baryon interaction in [12] and in [13] where a good reproduction of the \( \Delta \) resonance was obtained using second order parameters of natural size. The N/D method has also been used for \( \pi N \) scattering [14] and in the \( K^-N \) and coupled channels system in [15]. A review of these unitary methods can be seen in [16]. The consideration of coupled channels to study meson baryon interactions at intermediate energies has also been exploited in [17] using the K-matrix approach, although not within a chiral context.

The Bethe Salpeter equation was also used in the study of the meson baryon interaction in the strangeness \( S = -1 \) sector in [18] and in the \( S = 0 \) sector around the \( N^*(1535) \) region in [19]. In this latter work, aimed at determining the \( N^*N^+\pi \) coupling, only the vicinity of the resonance was studied and no particular attention was given to the region of lower energies. Subsequently a work along the same lines using the Bethe Salpeter equation, but considering all the freedom of the chiral constraints, was done in [20] and a good reproduction of the experimental observables was obtained for the \( I = 1/2 \) sector. Those works considered only states of meson baryon in the coupled channels and both in [19] and [20] the \( \pi\pi N \) channel was omitted. This channel plays a moderate role in the \( I = 1/2 \) sector [21] but, as we shall see, it plays a crucial role in the \( I = 3/2 \) sector.

Our aim in the present work is to extend the chiral unitary approach to account for the \( \pi\pi N \) channel, including simultaneously some other corrections inspired by vector meson dominance (VMD) which finally allow one to have a reasonable description of the meson baryon interaction up to meson baryon energies of around 1600 MeV. The \( N^*(1535) \) resonance is generated dynamically in this approach and the mass, width and branching ratios are obtained in fair agreement with the experiment. The phase shifts and inelasticities for \( \pi N \) scattering in that region are also evaluated and good agreement with experiment is also found both in the \( I = 1/2 \) and \( I = 3/2 \) sectors. In addition some trace of the \( \Delta(1620) \) is found, linked to the introduction of the \( \pi\pi N \) channel, with a pole in the second Riemann sheet with the right energy, albeit a large width.

A side effect of the calculations is that we determine the s-wave part of the \( \pi N \rightarrow \pi\pi N \) transition amplitude, revising previous determinations in [23] and [24], and together with the P-wave amplitudes previously determined, we obtain a good reproduction of the cross sections for these reactions.

2 \( \pi N \) scattering in a 2-body coupled channel model

2.1 Basic 2-body model

In this section we study the meson baryon scattering in S-wave in the strangeness \( S = 0 \) sector. We shall make use of the Bethe Salpeter equation in coupled channels considering states of a meson of the 0\(^-\) octet and a baryon of the 1/2\(^+\) octet, as required by the SU(3) chiral formalism. For total zero charge we have six channels, \( \pi^-p, \pi^0n, \eta n, K^+\Sigma^-, K^0\Sigma^0, \) and \( K^0\Lambda. \)
Table 1: $C_{ij}$ coefficient in the potential. $C_{ij} = C_{ji}$

| $K^+\Sigma^-$ | $K^0\Sigma^0$ | $K^0\Lambda$ | $\pi^-p$ | $\pi^0n$ | $\eta\eta$ |
|----------------|---------------|--------------|----------|----------|---------|
| $K^+\Sigma^-$  | 1             | $-\sqrt{2}$  | 0        | 0        | $-\frac{1}{\sqrt{2}}$ |
| $K^0\Sigma^0$  | 0             | 0            | $-\frac{1}{\sqrt{2}}$ | $-\frac{1}{2}$ | $\frac{\sqrt{3}}{2}$ |
| $K^0\Lambda$   | 0             | $-\frac{1}{\sqrt{2}}$ | $\frac{\sqrt{3}}{2}$ | $-\frac{3}{2}$ | $\frac{1}{\sqrt{2}}$ |
| $\pi^-p$       | 0             | $\frac{1}{\sqrt{2}}$ | 0        | 0        | 0       |
| $\pi^0n$       | 0             | 0            | 0        | 0        | 0       |
| $\eta\eta$     | 0             | 0            | 0        | 0        | 0       |

The Bethe Salpeter equation is given by

$$T = V + VGT$$  \hspace{1cm} (1)$$

where $G$ is the product of the meson and baryon propagators. The diagrammatic expression of the $T$ matrix is shown in Fig. 1. Following [18] we take the kernel (potential) of the Bethe Salpeter equation from the lowest order chiral Lagrangian involving mesons and baryons

$$\mathcal{L}_{MB\rightarrow MB'} = Tr \left[ \bar{B}i\gamma^\mu \frac{1}{4f^2} \left\{ (\phi \partial_\mu \phi - \partial_\mu \phi \phi) B - B (\phi \partial_\mu \phi - \partial_\mu \phi \phi) \right\} \right]$$ \hspace{1cm} (2)$$

where $B$ and $\phi$ are the SU(3) matrices for the octet baryon field and the octet meson field respectively, and $f$ is the weak decay constant of the meson. From this Lagrangian, the transition potentials between our six channels are given by

$$V_{ij} = -C_{ij} \frac{1}{4f^2} \bar{u}(p') \gamma^\mu u(p) (k_\mu + k'_\mu)$$ \hspace{1cm} (3)$$

with the initial(final) baryon spinor $u(p)$ ($u(p')$) and the initial(final) meson momentum $k$ ($k'$).

The coefficients $C_{ij}$, reflecting the SU(3) symmetry of the problem, are obtained from eq. (2) and shown in Table 1.

We are interested in the value of the $T$ matrix element for the on-shell meson-baryon system at a certain center of mass energy $\sqrt{s}$ or $P \equiv p + k = (\sqrt{s}, 0, 0, 0)$, and we express it as $T(\sqrt{s})$. Yet, in the diagrammatic expression of the Bethe Salpeter equation, Fig. 1, one can see that the $V$ and $T$ matrices in the second diagram on the right hand side, can be (half) off-shell since the BS equation is an integral equation. However, it was shown in [18] that the off shell part of these matrices in the loops could be incorporated into a renormalization of the lowest order Lagrangian and hence only the on shell parts are needed. Thus, they factorize out of the integral and the original BS integral equation is then reduced to an algebraic equation which is easily solved with the solution in matrix form

$$T(\sqrt{s}) = [V(\sqrt{s})^{-1} - G(\sqrt{s})]^{-1} \quad \text{or} \quad T(\sqrt{s})^{-1} = V(\sqrt{s})^{-1} - G(\sqrt{s})$$ \hspace{1cm} (4)$$

where the $G$ function is a diagonal matrix representing the loop integral of a meson and a baryon. The $i$-th element is thus expressed as

$$G_i(P) = i \int \frac{d^4q}{(2\pi)^4} \frac{2M_i}{(P - q)^2 - M_i^2 + i\epsilon} \frac{1}{q^2 - m_i^2 + i\epsilon}$$ \hspace{1cm} (5)$$
with $M_i$ the baryon mass and $m_i$ the meson mass.

In the present (Mandl and Shaw) normalization \[2\], the T matrix is related to the S matrix as

$$S_{ij}(P_i, P_j) = 1 - i(2\pi)^4\delta^4(P_i - P_j) \frac{1}{V^2} \sqrt{\frac{M_i}{E_i}} \sqrt{\frac{M_j}{E_j}} \frac{1}{2\omega_i} \sqrt{\frac{1}{2\omega_j}} T_{ij}(P_i, P_j)$$

(6)

where $V$ is the volume of the normalization box, $E_i$ ($E_j$) and $\omega_i$ ($\omega_j$) are the energies of the incoming (outgoing) baryon and meson respectively. In this notation, the unitarity condition for any partial wave amplitude (in particular the S-wave which is our case) is given by

$$\text{Im}[T_{ij}(\sqrt{s})] = -\frac{M_i Q_k(\sqrt{s})}{4\pi\sqrt{s}} T_{kj}(\sqrt{s})$$

or

$$\text{Im}[T^{-1}(\sqrt{s})]_{ij} = \delta_{ij} \frac{M_i Q_i(\sqrt{s})}{4\pi\sqrt{s}}$$

(7)

where

$$Q_i(\sqrt{s}) = \frac{\sqrt{(s - (M_i + m_i)^2)(s - (M_i - m_i)^2)}}{2\sqrt{s}} \theta(\sqrt{s} - (M_i + m_i))$$

(8)

is the on-shell center of mass momentum of $i$-th meson-baryon system.

The matrix elements of the potential which we substitute into eq. (4) is

$$V_{ij}(\sqrt{s}) = -C_{ij} \frac{1}{4f_i f_j} (2\sqrt{s} - M_i - M_j) \sqrt{\frac{M_i + E_i(\sqrt{s})}{2M_i}} \sqrt{\frac{M_j + E_j(\sqrt{s})}{2M_j}}$$

(9)

where we introduce different weak decay constants for different mesons. We use the values

$$f_\pi = 93 \text{ MeV} , \ f_K = 1.22 f_\pi , \ f_\eta = 1.3 f_\pi$$

(10)

taken from $\chi$PT \[4\].

The meson-baryon 2-body propagator which we substitute into equation (4) is

$$G_i(\sqrt{s}) = \frac{2M_i}{(4\pi)^2} \left\{ a_i(\mu) + \log \frac{m_i^2}{\mu^2} + \frac{M_i^2 - m_i^2 + s}{2s} \log \frac{M_i^2}{m_i^2} \right\}$$

$$+ \frac{Q_i(\sqrt{s})}{\sqrt{s}} \left[ \log \left(s - (M_i^2 - m_i^2) + 2\sqrt{s}Q_i(\sqrt{s})\right) + \log \left(s + (M_i^2 - m_i^2) + 2\sqrt{s}Q_i(\sqrt{s})\right) \right.$$

$$\left. - \log \left(-s + (M_i^2 - m_i^2) + 2\sqrt{s}Q_i(\sqrt{s})\right) - \log \left(-s - (M_i^2 - m_i^2) + 2\sqrt{s}Q_i(\sqrt{s})\right) \right\}$$

(11)

which is the 1-loop integral \[5\] done with dimensional regularization. Its infinity is canceled by higher order counter-terms. The first terms $a_i(\mu)$ are real constants and stand for the finite contribution of such counter-terms. We treat these $a_i(\mu)$ as unknown parameters and determine them from fits to the data. The imaginary part of the above propagator is

$$\text{Im}[G_i(\sqrt{s})] = -\frac{M_i Q_i(\sqrt{s})}{4\pi\sqrt{s}}$$

(12)

which leads, using eq. (4), to eq. (7). Therefore, in the present model, unitarity is exactly fulfilled.

In order to keep isospin symmetry in the case that the masses of the particles in the same multiplet are equal, we choose $a_i(\mu)$ to be the same for the states belonging to the same isospin
Figure 2: Propagators of the meson-baryon systems using the parameters of eq (13). The $K^0\Sigma^0$ and $\pi^0n$ propagators are omitted because they are almost the same as those of $K^+\Sigma^-$ and $\pi^-p$ respectively. The continuous(dashed) lines stand for the real(imaginary) part.

In Fig.2 we show the $G$ matrix elements which are obtained with this set of parameters. These propagators are essentially the same as those obtained in [19] where the regularization was done using a three-momentum cutoff ($|\vec{q}|<1$ GeV)

$$\text{Re}[G_i(\sqrt{s})] = \mathcal{P} \int_{1\text{GeV}} 4\pi^2 d^3\vec{q} \frac{M_i}{(2\pi)^3 E(\vec{q})} \frac{1}{\sqrt{s} - E(\vec{q}) - \omega(\vec{q})/2\omega(\vec{q})} + \tilde{a}_i$$  (14)

with $E(\vec{q}) = \sqrt{M_i^2 + \vec{q}^2}$, $\omega(\vec{q}) = \sqrt{m_i^2 + \vec{q}^2}$ and

$$\tilde{a}_{\pi N} = 35 \text{ MeV}, \quad \tilde{a}_{\eta N} = 16 \text{ MeV}, \quad \tilde{a}_{K \Lambda} = 40 \text{ MeV}, \quad \tilde{a}_{K \Sigma} = -21 \text{ MeV}$$  (15)

where $\mathcal{P}$ means the Cauchy principal value.

The resulting T matrix elements of $S_{11}$ (isospin 1/2) and $S_{31}$ (isospin 3/2) $\pi N$ elastic scattering are shown in Fig.3. In these graphs we plot the quantity

$$-\sqrt{\frac{M_i Q_i(\sqrt{s})}{4\pi\sqrt{s}}} \sqrt{\frac{M_j Q_j(\sqrt{s})}{4\pi\sqrt{s}}} T_{ij}(\sqrt{s})$$  (16)

in order to compare with the data of the CNS analysis [25]. We find a qualitative agreement with the data in the energy range from threshold to 1600 MeV. In the figure of the experimental analysis one can see the manifestation of the resonances $N^*(1535)$, $N^*(1650)$ in the $S_{11}$ amplitude.
Figure 3: Scattering amplitude for the $S_{11}$ and $S_{31}$ $\pi N$ partial waves. The left and right figures stand for the amplitudes calculated in our model and the data analysis \[25\] respectively. The continuous(dashed) lines stand for the real( imaginary) part.

and $\Delta(1620)$ in the $S_{31}$ one. The calculated $S_{11}$ amplitude also exhibits a resonance structure around 1535 MeV. The generation of this resonance is common to all the unitary chiral approaches \[8, 13, 20\]. In section 4, after we include new elements in the theory, we shall investigate this resonance by searching for poles in the second Riemann sheet of the complex plane.

At energies beyond 1600 MeV, the calculated amplitudes are qualitatively different from the data, and the $N^*(1650)$ and $\Delta(1620)$ do not show up. In the philosophy that the resonances obtained using the lowest order Lagrangian and the present unitary scheme are simply meson baryon scattering resonances, (qualifying for quasibound meson baryon states \[16\]), the nongeneration of a particular resonance would indicate that it is mostly a genuine state (approximately a 3q system). However, such resonances could be also obtained in a unitary approach provided one used information related to this resonance which would be incorporated in the higher order Lagrangians. For the case of the meson meson interaction it is known \[26\] that the $O(\rho^3)$ Lagrangian is saturated by the exchange of vector meson resonances, which are not generated in the BS approach of \[8\]. Actually, in \[20\] the $N^*(1650)$ resonance is also reproduced by introducing counter terms which effectively account for higher order corrections, much in the way as the (genuine) $\rho$ resonance was reproduced in the study of the meson meson scattering in \[27, 28\]. As quoted before, the agreement below 1600 MeV is only qualitative. Indeed, both the real and imaginary parts of the $S_{11}$ amplitude are somewhat overestimated in the theory, and so is the case for the $S_{31}$ amplitude where the theoretical imaginary part clearly overestimates the experimental one.

The phase-shifts $\delta_i(\sqrt{s})$ and elasticities $\eta_i(\sqrt{s})$ are given by

$$\delta_i(\sqrt{s}) = \frac{1}{2} \arccos \left[ \text{Re} \left[ \frac{1 - 2i \frac{M_i Q_i}{4\pi \sqrt{s}} T_{ii}}{1 - 2i \frac{M_i Q_i}{4\pi \sqrt{s}} T_{ii}} \right] \right] \times \text{sign} \left[ \text{Re} \left[ -T_{ii} \right] \right]$$  \hspace{1cm} (17)

$$\eta_i(\sqrt{s}) = \left| 1 - 2i \frac{M_i Q_i}{4\pi \sqrt{s}} T_{ii} \right|.$$  \hspace{1cm} (18)
Figure 4: Phase-shifts and inelasticities for $S_{11}$ and $S_{31} \pi N$ scattering. The continuous (dotted) lines correspond the calculations (data analysis [25]).

Fig. 4 shows the phase-shifts and inelasticities. In the phase-shifts graph we can see again the qualitative agreement at energies below 1600 MeV. On the other hand, the inelasticities are not reproduced below the first open meson baryon threshold. In this 2-body model the threshold of inelastic scattering for the $S_{11}$ case is the $\eta n$ threshold which appears at 1487 MeV. Below this energy, the calculated inelasticities are zero and do not agree with the data. This situation is even clearer in the $S_{31}$ case. The threshold of inelastic scattering is in this case the $K\Sigma$ threshold which appears at 1690 MeV. The big inelasticities observed in the data below that energy are not reproduced in the present 2-body approach. The only inelastic channel opened below that energy is the $\pi\pi N$ channel, and the experimental data is telling us that the influence of this channel in the $S_{31}$ amplitude should be very important. We will include the $\pi\pi N$ channel in the next section.

2.2 Improved 2-body model

The vector meson dominance (VMD) hypothesis is phenomenologically very successful. In this hypothesis, the meson baryon interaction is provided by vector meson exchange. For example, the $\pi N \to \pi N$ process is described by $\rho$ meson exchange in the $t$-channel, as shown in Fig 5. It is interesting to note that the result from $\rho$ exchange provides the amplitude obtained from the lowest order chiral Lagrangian. For example, in the case of $\pi^- p \to \pi^- p$, $\rho$ exchange in the $t-$channel gives (see [29] for the $\rho NN$ coupling within the VMD hypothesis)

$$\left. i \frac{m_v G_v}{2 f^2} \gamma^\mu \epsilon_\mu \frac{i}{q^2 - m_v^2} \frac{m_v G_v}{f^2} \epsilon^{\nu(k + k')}_{\nu} \right|_{q^2=0} = -i \frac{1}{4 f^2} \gamma^\mu (k + k')_\mu$$

(19)
which follows from the relation $G_2^2/f^2 = 1/2$, which is a result of the VMD hypothesis. This indicates that the lowest order chiral Lagrangian is an effective manifestation of the VMD mechanism in the vector field representation of the vector mesons. According to this consideration, we introduce in the chiral coefficient a correction to account for the dependence on the momentum transfer of the $\rho$ propagator. Thus we replace

$$C_{ij} \rightarrow C_{ij} \times \int \frac{d\hat{k}'}{4\pi} \frac{-m_v^2}{(k' - k)^2 - m_v^2} \text{ at } \sqrt{s} > \sqrt{s_{ij}^0} \quad (20)$$

where $\sqrt{s_{ij}^0}$ is the energy where the integral of eq. (20) is unity, and which appears in between the thresholds of the two $i, j$ channels. At very low energies where $\chi PT$ is used, this correction is negligible but this is not the case at the intermediate energies studied here. For example, the correction for $\pi^-p \rightarrow \pi^-p$ element is calculated as

$$\int \frac{d\hat{k}'}{4\pi} \frac{-m_{\rho}^2}{(k' - k)^2 - m_{\rho}^2} = \frac{m_{\rho}^2}{4k'k} \log \frac{m_{\rho}^2 + 2k'k\rho + 2kk' - m_{\pi}^2 - m_{\pi}^2}{m_{\rho}^2 + 2k'k\rho - 2kk' - m_{\pi}^2 - m_{\pi}^2} \quad (21)$$

with $m_{\rho} = 770\text{[MeV]}$, and is shown in Fig.6 left. One can see that $\rho$ meson tail reduces the coefficient about 25% at energies around 1500 MeV. Similarly, for the strangeness exchanging process, we consider $K^*$ exchange in the t-channel. For example, the correction of $\pi^-p \rightarrow K^0\Lambda$ is calculated with $m_{K^*} = 892\text{ MeV}$ and shown in Fig.6 right.

With this correction, after retuning the subtraction constants $a_i(\mu)$, we obtain the T matrix shown in Fig.7. As we can see, the problem of the previous overestimation is nearly solved. Especially, a drastic improvement is achieved for the $S_{31}$ amplitude. The phase-shifts are better.
reproduced now as shown in Fig. 8. These results show that the correction of eq. (20) is important and leads to improved results with respect to the plain use of the standard lowest order chiral Lagrangian. In the following sections, we employ this modified coefficient. The calculated inelasticities with this coefficient, are almost the same as before and show the lack of some important channels. We come back to this problem in the next section.

3 πN scattering in a 2-3-body coupled channel model

In this section, we extend our model to include the ππN channels. The cross sections of the πN → ππN scattering are known experimentally and they are sizeable compared with the two body cross sections. In this paper, we include only the transition potential between πN and ππN and disregard the coupling between the \{KΣ, KΛ, ηn, ππN\} states and the ππN. This is a simplification forced by the ignorance of such couplings, but the larger mass of these states with respect to πN, and the fact that we are talking about corrections, make this simplification justifiable.

3.1 πN → ππN process

In the isospin formalism, the πN → ππN transition amplitudes can be classified by the total isospin $I$ and the isospin of the final two pions $I_{ππ}$, and the corresponding amplitudes are written as $A_{2II_{ππ}}$. The amplitudes of the physical processes are expressed in terms of the following four
Figure 9: $\pi N \rightarrow \pi\pi N$ process

Independent isospin amplitudes

$$
A_{11} = a_{11} \chi_f \bar{\sigma} \cdot (k'_1 - k'_2) \chi_i \quad , \quad A_{31} = a_{31} \chi_f \bar{\sigma} \cdot (k'_1 - k'_2) \chi_i
$$

$$
A_{10} = a_{10} \chi_f \bar{\sigma} \cdot \vec{k} \chi_i \quad , \quad A_{32} = a_{32} \chi_f \bar{\sigma} \cdot \vec{k} \chi_i
$$

where $\chi_i$ and $\chi_f$ are spinors for the initial and final nucleon, and $k_1$, $k'_1$ and $k'_2$ are the momenta of the pions depicted in Fig.9. Among these amplitudes, the upper two amplitudes which have $I_{\pi\pi} = 1$ correspond to transitions from $\pi N$ in an S-wave, while the lower two amplitudes correspond to the transition in P-wave.

These amplitudes have been extracted by analyzing the experimental cross sections. In ref. [23], the data from threshold to 1470 MeV are analyzed. The reduced amplitudes $a_{ij}$ are assumed to be constant except for $a_{10}$ which has a resonance behavior due to a coupling to the Roper resonance, $P_{11}(1440)$,

$$
a_{10} (\sqrt{s}) = a'_{10} \frac{M - \sqrt{s_{th}}}{M - \sqrt{s} - \frac{\Gamma}{2} (\sqrt{s} - \sqrt{s_{th}})^2} \quad (23)
$$

where $\sqrt{s_{th}} \sim 1213$ MeV is the threshold energy. The reduced amplitudes obtained are

$$
a_{11} = 10.61 \pm 0.62 [m^{-3}_\pi] \quad , \quad a_{31} = -6.02 \pm 0.31 [m^{-3}_\pi]
$$

$$
a'_{10} = 6.63 \pm 0.21 [m^{-3}_\pi] \quad , \quad a_{32} = 2.75 \pm 0.13 [m^{-3}_\pi] \quad (24)
$$

with $M = 1416 \pm 14$ MeV and $\Gamma = 287 \pm 43$ MeV. In ref. [24], the data close to threshold, including newer data with respect to [23], are analyzed. In this case the reduced amplitudes are assumed to depend linearly on the center of mass energy. The reduced amplitudes

$$
a_{11} = 3.3 \pm 0.8 + (0.9 \pm 2.0)(\sqrt{s} - \sqrt{s_{th}})/m_\pi [m^{-3}_\pi] \quad (25)
$$

$$
a_{31} = -5.0 \pm 2.2 + (15.0 \pm 4.2)(\sqrt{s} - \sqrt{s_{th}})/m_\pi [m^{-3}_\pi] \quad (26)
$$

$$
a_{10} = 6.55 \pm 0.16 + (10.4 \pm 0.8)(\sqrt{s} - \sqrt{s_{th}})/m_\pi [m^{-3}_\pi] \quad (27)
$$

$$
a_{32} = 2.07 \pm 0.10 + (1.98 \pm 0.33)(\sqrt{s} - \sqrt{s_{th}})/m_\pi [m^{-3}_\pi] \quad (28)
$$

are obtained.

We plot both empirical reduced amplitudes in Fig.10. One can see that the extracted amplitudes of S-wave $\pi N$ are very different in both analyses, while those of P-wave $\pi N$ agree quite well. These discrepancies reflect the difficulties to determine the amplitudes of the S-wave $\pi N$ from ($\pi, 2\pi$) cross section data, which looks quite natural since most of the processes are dominated by the transition from P-wave. Therefore, in this paper, we leave free the S-wave $\pi N$ amplitudes, $a_{11}(\sqrt{s})$ and $a_{31}(\sqrt{s})$, and determine them through the present study so that they are compatible with the data of $\pi N \rightarrow \pi N$ elastic scattering.
state. The terms of the reduced potentials \( v \) equation with all the channels. Note that, in our formalism, the reduced amplitudes \( a \) do not include the \( \pi\piN \) channels including \( \pi\piN \). We consider the Bethe-Salpeter equation for the scattering matrix, eq. (1) with the eight coupled \( \piN \) state. We introduce the baryon-two meson propagator corresponding to Fig.11. Its Imaginary part is finite and, neglecting the contribution of the negative energy of the baryon, the potentials of the \( \piN \) state, we introduce the baryon-two meson propagator corresponding to Fig.11.

\[ V_{\pi^-p, \pi^0n^{-p}} = \left[ \frac{\sqrt{3}}{3} v_{11} + \frac{\sqrt{2}}{6} v_{31} \right] \chi_f^\dagger \vec{\sigma} \cdot (\vec{k}_1 - \vec{k}_2) \chi_i - \frac{\sqrt{10}}{10} v_{32} \chi_f^\dagger \vec{\sigma} \cdot \vec{k} \chi_i \]  

\[ V_{\pi^-p, \pi^+n^{-n}} = \left[ \frac{1}{3} v_{11} - \frac{1}{3} v_{31} \right] \chi_f^\dagger \vec{\sigma} \cdot (\vec{k}_1 - \vec{k}_2) \chi_i + \left[ \frac{\sqrt{2}}{3} v_{10} - \frac{\sqrt{5}}{15} v_{32} \right] \chi_f^\dagger \vec{\sigma} \cdot \vec{k} \chi_i \]  

\[ V_{\pi^0n, \pi^0n^{-p}} = \left[ -\frac{1}{3} v_{11} + \frac{1}{3} v_{31} \right] \chi_f^\dagger \vec{\sigma} \cdot (\vec{k}_1 - \vec{k}_2) \chi_i - \frac{\sqrt{5}}{5} v_{32} \chi_f^\dagger \vec{\sigma} \cdot \vec{k} \chi_i \]  

\[ V_{\pi^0n, \pi^+n^{-n}} = \left[ -\frac{\sqrt{2}}{6} v_{11} - \frac{\sqrt{2}}{3} v_{31} \right] \chi_f^\dagger \vec{\sigma} \cdot (\vec{k}_1 - \vec{k}_2) \chi_i + \left[ -\frac{1}{3} v_{10} - \frac{\sqrt{10}}{15} v_{32} \right] \chi_f^\dagger \vec{\sigma} \cdot \vec{k} \chi_i \]  

in terms of the reduced potentials \( v_{11}(s) \), \( v_{31}(\sqrt{s}) \), \( v_{10}(\sqrt{s}) \) and \( v_{32}(\sqrt{s}) \), which correspond to the reduced amplitudes \( a_{11}(\sqrt{s}) \), \( a_{31}(\sqrt{s}) \), \( a_{10}(\sqrt{s}) \) and \( a_{32}(\sqrt{s}) \) respectively, after solving the BS equation with all the channels. Note that, in our formalism, \( \pi^+ \) corresponds to the \( -|I = 1, I_z = 1| \) state. The terms of \( v_{10}(\sqrt{s}) \) and \( v_{32}(\sqrt{s}) \) do not contribute in the present S-wave scattering.

The potentials of the \( \piN \) do not couple to the S-wave \( \piN \) state.

3.2 The model including the \( \pi\piN \) channel

We consider the Bethe-Salpeter equation for the scattering matrix, eq. (1) with the eight coupled channels including \( \pi\piN \), namely, \( \pi^-p \), \( \pi^0n \), \( \eta \), \( K^+\Sigma^- \), \( K^0\Sigma^0 \), \( K^0\Lambda \), \( \pi^0\pi^-p \) and \( \pi^+\pi^-n \). We do not include the \( \pi^0\pi^0n \) channel because it does not couple to the S-wave \( \piN \) state.

The integrals in eq. (33) is strongly divergent. Its Imaginary part is finite and, neglecting the contribution of the negative energy of the baryon, the potentials of the \( \pi\piN \) state, we introduce the baryon-two meson propagator corresponding to Fig.11:

\[ \tilde{G}(P) = i^2 \int \frac{d^4q_1}{(2\pi)^4} \int \frac{d^4q_2}{(2\pi)^4} (q_1 - \vec{q}_2)^2 \frac{2M_N}{(P - q_1 - q_2)^2 - M_N^2 + i\epsilon} \frac{1}{q_1^2 - m_1^2 + i\epsilon} \frac{1}{q_2^2 - m_2^2 + i\epsilon} \]

which includes the vertex structure for convenience. The integral in eq. (33) is strongly divergent. Its Imaginary part is finite and, neglecting the contribution of the negative energy of the baryon,
where the meson-baryon propagators that we obtain in the new fit to the data, are ππN which are a little changed from the previous values omitting the try to reproduce the experimental elastic πN is given by,

\[ \text{Im}[\tilde{G}(\sqrt{s})] = -\frac{M_N}{4(2\pi)^3} \int d\omega_1 \int d\omega_2 \left[ M_N^2 + 2q_1(\omega_1)^2 + 2q_2(\omega_2)^2 - (\sqrt{s} - \omega_1 - \omega_2)^2 \right] \theta(1 - A^2) \] (34)

where

\[ A = \frac{(\sqrt{s} - \omega_1 - \omega_2)^2 - M_N^2 - q_1(\omega_1)^2 - q_2(\omega_2)^2}{2q_1(\omega_1)q_2(\omega_2)} \] (35)

with \( q_i(\omega_i) = \sqrt{\omega_i^2 - m_i^2} \). This imaginary part, reflecting the phase space for the intermediate baryon-two meson system, is shown in Fig.12. On the other hand, the real part of \( \tilde{G}(\sqrt{s}) \), in the renormalized model, is not fixed. The situation is well illustrated in a dispersion relation

\[ \text{Re}[\tilde{G}(\sqrt{s})] = \frac{(\sqrt{s} - w_0)\theta}{\pi} \int_{\sqrt{s}}^{w_{\text{max}}} dw \frac{\text{Im}[\tilde{G}(w)]}{(w - w_0)(w - \sqrt{s})} + A + B(\sqrt{s} - w_0) + C(\sqrt{s} - w_0)^2 + D(\sqrt{s} - w_0)^3 + E(\sqrt{s} - w_0)^4 + F(\sqrt{s} - w_0)^5 \] (36)

where six arbitrary constants \( A \sim F \) are introduced because \( \text{Im}[\tilde{G}(\sqrt{s})] \) grows as

\[ \lim_{\sqrt{s} \to \infty} \frac{\text{Im}[\tilde{G}(\sqrt{s})]}{\sqrt{s}^n} \to \begin{cases} -\infty & \text{for } n \leq 5 \\ 0 & \text{for } n \geq 6 \end{cases} \] (37)

which is easily proved by an actual calculation or dimensional considerations. Therefore, in this paper, we treat \( \text{Re}[\tilde{G}(\sqrt{s})] \) as a free function and look for reasonable values consistent with the experiment.

### 3.3 Final results

By varying the potential \( v_{11}(\sqrt{s}) \) and \( v_{31}(\sqrt{s}) \), the subtraction constants \( a_i(\mu) \) and \( \text{Re}[\tilde{G}(\sqrt{s})] \), we try to reproduce the experimental elastic πN T matrix and also the \( \pi N \to \pi \pi N \) cross sections. For the \( v_{11}(\sqrt{s}) \) and \( v_{31}(\sqrt{s}) \) functions we employ a real polynomial function, and for \( \text{Re}[\tilde{G}(\sqrt{s})] \) we test several types of functions. In Fig.13 we show the propagators \( G(\sqrt{s}) \) and \( \tilde{G}(\sqrt{s}) \). The subtraction parameters \( a_i(\mu) \) for the meson-baryon propagators that we obtain in the new fit to the data, are

\[ \mu = 1200 \text{ MeV}, \quad a_{\pi N}(\mu) = 2.0, \quad a_{\eta N}(\mu) = 0.1, \quad a_{K\Lambda}(\mu) = 1.5, \quad a_{K\Sigma}(\mu) = -2.8 \] (38)

which are a little changed from the previous values omitting the \( \pi \pi N \) channels. For the \( \tilde{G}(\sqrt{s}) \) case the real part is taken zero. We find that the best results are obtained with functions compatible.
with zero. This result is similar to the one found in [30] where the real part of the three pion loop form $\phi$ decay was also found negligibly small.

Fig. 14 shows the functions $a_{11}(\sqrt{s})$ and $a_{31}(\sqrt{s})$ determined in this study. In the upper two graphs, the potentials $v_{11}(\sqrt{s})$ ($v_{31}(\sqrt{s})$) and the amplitudes $a_{11}(\sqrt{s})$ ($a_{31}(\sqrt{s})$), which come after unitarization, are shown. The thin lines correspond to the following potentials which we finally use

\begin{align*}
v_{11}(\sqrt{s}) &= 4.0 + 1.0(\sqrt{s} - 1213) / m_\pi \, [m_\pi^{-3}] \quad (39) \\
v_{31}(\sqrt{s}) &= -5.60(\sqrt{s} - 1470) / m_\pi - 1.05(\sqrt{s} - 1470)^2 / m_\pi^2 + 1.77(\sqrt{s} - 1470)^3 / m_\pi^3 + 0.66(\sqrt{s} - 1470)^4 / m_\pi^4 - 0.17(\sqrt{s} - 1470)^5 / m_\pi^5 - 0.07(\sqrt{s} - 1470)^6 / m_\pi^6 \, [m_\pi^{-3}] \, . \quad (40)
\end{align*}

The continuous line and dashed line correspond to the real and imaginary part of $a_{11}(\sqrt{s})$ ($a_{31}(\sqrt{s})$) respectively. One can see that the imaginary parts are almost negligible as assumed in the paper [23] and [24]. In the lower two graphs, the real part of $a_{11}(\sqrt{s})$ ($a_{31}(\sqrt{s})$) is plotted in comparison with the two empirical ones. The lower energy part of the calculated $a_{11}(\sqrt{s})$ agrees with that of the paper [24] but it is quite different from the one of the [23]. On the other hand our calculated $a_{31}(\sqrt{s})$ amplitude is different from both [23] and [24]. We should note that, while it is possible to reproduce the $\pi N \rightarrow \pi \pi N$ cross sections with the three set of amplitudes, a simultaneous

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig13}
\caption{Propagators of meson-baryon and $\pi \pi N$ systems using the parameters of eq (38). The solid and dashed lines are real and imaginary parts respectively.}
\end{figure}
description of the $\pi N \rightarrow \pi \pi N$ cross sections and the $\pi N \rightarrow \pi N$ scattering date is not possible with the amplitude of $[23]$ and $[24]$. We shall elaborate further on this issue below.

The T matrix elements obtained are shown in Fig.15. One can see that the T matrix elements are well reproduced at energies below 1600 MeV in both the $S_{11}$ and $S_{31}$ cases. The phase-shifts and inelasticities are shown in Fig.16. The inclusion of the $\pi \pi N$ channels improves slightly the phase shifts in $S_{11}$ and $S_{31}$. The important thing to note is that, as seen in Fig.16, the inelasticities at low energies in both $S_{11}$ and $S_{31}$ are well reproduced with the inclusion of the $\pi \pi N$ channels. The present $a_{11}(\sqrt{s})$ function is essentially the same as that of the paper $[24]$ in the range of energies studied there. Should we take the amplitude of paper $[23]$, the inelasticities would be much overestimated at energies around 1400 MeV. The present $a_{31}(\sqrt{s})$ amplitude is different from both empirical $a_{31}(\sqrt{s})$ determinations. It has a node at the energy 1470 MeV which is reflected in the inelasticities shown in the figure. The inelasticities are quite sensitive to the $a_{31}(\sqrt{s})$ amplitude used. For example, the two empirical $a_{31}(\sqrt{s})$ correspond to the inelasticities shown in Fig.17 which differ appreciable from those obtained with the function determined here.

We should note that for this test we have used a function $v_{31}(\sqrt{s})$ such that after unitarization they lead to scattering amplitudes identical to the empirical $a_{31}(\sqrt{s})$. The unitarization procedure modifies only little the potential as is visible in upper right box of Fig.14 for our case. The opposite sign of our $a_{31}(\sqrt{s})$ also provides the same inelasticities and hence is compatible with the $S_{31} \pi N$ scattering data. However, it leads to unacceptable results for the $\pi N \rightarrow \pi \pi N$ cross section.

Fig.18 shows the $\pi N \rightarrow \pi \pi N$ cross sections. They are calculated with the present S-wave amplitudes and the P-wave amplitudes of the paper $[23]$. The dashed lines correspond to the cross section when we drop the S-wave contributions. The two processes, $\pi^- p \rightarrow \pi^0 \pi^0 n$ and $\pi^+ p \rightarrow \pi^+ \pi^+ n$, are purely P-wave $\pi N$ and have no S-wave $\pi N$ contribution. In the $\pi^- p \rightarrow \pi^+ \pi^- n$ reaction, the P-wave contribution is large and dominates the process. The effect of the S-wave
Figure 15: Scattering amplitude for the $S_{11}$ and $S_{31}$ $\pi N$ partial waves with $\pi\pi N$ channels.

Figure 16: Phase-shifts and inelasticities of $S_{11}$ and $S_{31}$ $\pi N$ scattering with $\pi\pi N$ channels.
is not visible in the figure. However, in the $\pi^- p \to \pi^0 \pi^- p$ and $\pi^+ p \to \pi^0 \pi^+ p$ processes we can see that the P-wave contributions are small and do not explain the size of the data. As one can see, the present S-wave amplitude provides enough strength to account for the cross section data.

In the $\pi^- p \to \pi^0 \pi^- p$ process, the S-wave amplitude is a mixture of $a_{11}(\sqrt{s})$ and $a_{31}(\sqrt{s})$. In order to obtain the contribution of the S-wave shown in the figure, the amplitudes $a_{11}(\sqrt{s})$ and $a_{31}(\sqrt{s})$ should interfere constructively close to the $\pi\pi N$ threshold. The relative sign between $a_{11}(\sqrt{s})$ and $a_{31}(\sqrt{s})$ ($v_{11}(\sqrt{s})$ and $v_{31}(\sqrt{s})$) is determined by this condition. The value of $a_{11}/a_{31}$ at threshold is about $+1/2$, which is in contrast to the one pion exchange prediction, $-2$ \cite{31}. However, more elaborate models for two pion production \cite{32, 33, 34, 35, 36, 37} contain many more terms that change the value of this ratio. The amplitudes $a_{11}(\sqrt{s})$ and $a_{31}(\sqrt{s})$ determined in this study, account for both the $\pi N$ elastic scattering data and the $\pi N \to \pi\pi N$ cross section data simultaneously.

In Fig.19 we also show the result for the $\pi^- p \to \eta n$ cross section. We can see that the agreement is good up to 1550 MeV, above which higher partial waves, as demonstrated in \cite{38}, become relevant.

We have also evaluated the scattering lengths in our approach which are listed in Table 2. The thresholds for the $K^0 \Lambda$, $K^0 \Sigma^0$, $K^+ \Sigma^-$ are $\sqrt{s} = 1613, 1690, 1691$ MeV respectively. These energies, particularly the two last ones, are already in the region of energies where the theory deviates from experiment in the phase shifts and inelasticities, therefore we should take these numbers only as indicative. On the other hand, the fitting to the data has been done around the $N^*(1535)$ energy. Thus, our prediction for the $\eta n$ scattering length, $a_{\eta n} = 0.26 + i 0.25$ fm, should be rather accurate. This number is in agreement with the result quoted in \cite{8}, $a_{\eta n} = 0.20 + i 0.26$ fm, although a bit more attractive. Still the real part is about a factor three smaller than in \cite{21} and a factor four smaller than in \cite{39}. In spite of that, it was argued in \cite{8} that even the small value $\text{Re}[a_{\eta n}] = 0.2$ fm is not unrealistically small. This scattering length is important since it plays a crucial role in the possibility to have $\eta$ bound states in nuclei \cite{10, 11}. The scattering length for $\pi^0 n$ and $\pi^- p$ have not been imposed in the fit to the data, which concentrated in the $N^*(1535)$ region, as already mentioned. In this sense, the agreement with the data about 450 MeV below that resonance should be considered an unexpected success. We obtain isospin 3/2 and isospin 1/2 scattering lengths $a_3 = -0.0875 m_\pi^{-1}$, $a_1 = 0.1272 m_\pi^{-1}$, to be compared with the experimental numbers \cite{12}, $a_3^{\text{exp}} = -0.0852 \pm 0.0027 m_\pi^{-1}$, $a_1^{\text{exp}} = 0.1752 \pm 0.0041 m_\pi^{-1}$. The agreement is good for
Figure 18: The cross section of $\pi N \rightarrow \pi \pi N$ scattering. Data points are taken from the papers in reference of [24].

Figure 19: The cross section of $\pi N \rightarrow \eta n$ scattering.
Table 2: The calculated meson-baryon scattering lengths in unit of [fm].

|      | $\pi^0 n$ | $\pi^- p$ | $\eta n$ |
|------|-----------|-----------|----------|
| $a_i$ [fm] | -0.023    | 0.080 $+$ i 0.003 | 0.264 $+$ i 0.245 |

|      | $K^0 \Lambda$ | $K^0 \Sigma^0$ | $K^+ \Sigma^-$ |
|------|----------------|-----------------|----------------|
| $a_i$ [fm] | -0.148 $+$ i 0.165 | -0.205 $+$ i 0.068 | -0.284 $+$ i 0.090 |

the isospin 3/2 scattering length, but the isospin 1/2 one is about 25% smaller than experiment.

To summarize the result of section 2 and 3, we can see that the chiral unitary approach including the $\pi\pi N$ channels, is a very efficient tool to study the S-wave $\pi N$ scattering. It can reproduce, with few parameters, not only the isospin 1/2 part but also the isospin 3/2 part, which could not be obtained before [19, 20], when only meson-baryon channels were considered. Particularly, the $\pi\pi N$ channel was found essential to reproduce the isospin 3/2 scattering.

4 The $N^*(1535)$ and $\Delta(1620)$ resonances

As shown in Fig.13, the calculated $T(S_{11})$ has a resonance behavior around 1535 MeV indicating that the well known negative parity baryon $N^*(1535)$ is generated in this approach. To find the pole corresponding to the resonance we extend our calculation of the $T$ matrix to the complex $P_0$ plane. We evaluate the $T$ matrix elements by means of

$$T(P_0) = [V(P_0)^{-1} - G(P_0)]^{-1}$$

and look for poles in the complex $P_0$ plane. In this plane the function $G(P_0)$ has cuts on the real axis. For example, Fig.20 left shows $\text{Im}[G_{\pi^- p}(P_0)]$ in the physical sheet, namely the first Riemann sheet. We also plot to the right of Fig.20 the sheet connecting the first Riemann sheet for $\text{Im}[P_0] \geq 0$ with the second Riemann sheet for $\text{Im}[P_0] < 0$, which is defined as

$$G^{II}_i(P_0) = \begin{cases} G^I_i(P_0) & \text{at } \text{Re}[P_0] \leq \sqrt{s^0_i} \\ G^I_i(P_0) - 2i\text{Im}[G^I_i(P_0)] & \text{at } \text{Re}[P_0] > \sqrt{s^0_i} \end{cases}$$

with $\sqrt{s^0_i}$ the $i$-th channel threshold energy. We need also to extrapolate $\tilde{G}(\sqrt{s})$ to the complex plane. For this purpose we parameterize the result for $\text{Im}[\tilde{G}(\sqrt{s})]$ above the $\pi\pi N$ threshold in the real axis as

$$\text{Im}[\tilde{G}(\sqrt{s})] = -0.638(\sqrt{s} - 1213)/m_\pi + 1.124(\sqrt{s} - 1213)^2/m_\pi^2 - 0.882(\sqrt{s} - 1213)^3/m_\pi^3$$

which allows for an analytical continuation for $\text{Re}[P_0]$ above that threshold.

We search for poles of the isospin 1/2 $T$ matrix elements on this sheet, and obtain a pole at

$$P_0^R \equiv 1543 - i \ 46 \text{ MeV}.$$ 

The structure of the $T$ matrix guarantees that we find the pole in all the elements which have an isospin 1/2 component. For example, Fig.21 left shows $|T(S_{11})|$, where we can see a pole clearly. This result tells us that the decay width of the resonance is about 93 MeV. This value is smaller than the PDG estimation $100 \sim 250 \text{ MeV}$ [43], but agrees with the new data from BEPC, $95 \pm 15 \text{ MeV}$ [44].
On the other hand, in the elements of pure isospin 3/2 we find a pole around $1625 - i215$ MeV, which is reminiscent of the $\Delta(1620)$ resonance, although with a larger width than the nominal one of the PDG of about 120-160 MeV. In Fig.21 right we show $|T(S_{31})|$, where a pole is clearly visible. We should consider the position of the pole only as qualitative in our approach since around $\sqrt{s} = 1600$ MeV is where we start having noticeable discrepancies with the data and furthermore we had to go far in the complex plane where the analytic extrapolation of the $\pi\pi N$ propagator becomes less accurate. This resonance is responsible for the change of curvature in $\text{Im}T(S_{31})$ shown in Fig.15. It is interesting to note that the introduction of the $\pi\pi N$ channels is what has induced the appearance of this resonance, which does not show in our approach when the $\pi\pi N$ channels are not considered. In this respect it is interesting to note that the $\Delta(1620)$ resonance couples mostly to the $\pi\pi N$ channel [43].

For $P_0$ near the pole the T matrix elements are approximated by

$$T_{ij}(P_0) \simeq \frac{g_i g_j}{P_0 - P_0^R}$$

(45)
Table 3: Coupling constants and decay widths of $N^*(1535)$.

| Channel | $|g_i|$ | $\Gamma_i$ [MeV] | B. ratio [%] |
|---------|--------|------------------|--------------|
| $K^-\Sigma^-$ | 2.12   | 14.1             | 15.0         |
| $K^0\Sigma^0$ | 1.50   | 7.0              | 7.4          |
| $K^0\Lambda$ | 0.92   | 65.7             | 70.1         |
| $\pi^- p$ | 0.56   | 4.6              | 4.9          |
| $\pi^0 n$ | 0.39   | 2.4              | 2.5          |
| $\pi^- n$ | 1.84   | 0.57             | 0.57         |
| $m_{\pi}^{-2}$ | 0.40   |                  |              |
| $\Gamma_i$ [MeV] | 14.1   | 7.0              | 65.7         |
| B. ratio [%] | 15.0   | 7.4              | 70.1         |

with $g_i$ the couplings of the resonance to the $i$-th channel. We obtain the size of the couplings by evaluating the residues of the diagonal elements $T_{ii}(P_0)$. The values obtained are listed in Table 3. We find that the resonance $N^*(1535)$ couples strongly to the $K\Sigma$ and $\eta n$ channels strongly with a couplings four times bigger than for the $\pi N$ channels. The couplings to the $K\Lambda$ are also large compared to the $\pi N$ channels. In short, we get

$$|g_{\pi N}| < |g_{K\Lambda}| < |g_{\eta n}| \sim |g_{K\Sigma}|.$$ (46)

Using these couplings we calculate the partial decay widths of the open channels by means of

$$\Gamma_i = -2\text{Im}[G_i(M_{N^*})]|g_i|^2$$ (47)

where we take $M_{N^*} = \text{Re}[P_0^R] = 1543$ MeV. The partial decay rates and the branching ratios obtained are also listed in Table 3. The calculated branching ratios of $\pi N$, $\eta N$ and $\pi\pi N$ decay modes, are 22%, 70% and 7% respectively. The fraction of $\eta N$ mode is large, which is know to be characteristic of this resonance although our fraction is bigger than the PDG estimation 30 ~ 55 %. Our $\pi N$ fraction is smaller than the PDG estimation, 35 ~ 55 %, while the $\pi\pi N$ fraction is compatible with the PDG estimation, $\leq 10 \%$.

The lower part of Table 3 shows the same quantities obtained from a Breit-Wigner fit of the real energy scattering amplitudes $T_{ij}(\sqrt{s})$. We fit them by the Breit-Wigner form together with a background

$$T_{ij}(\sqrt{s}) = g_i g_j \frac{1}{\sqrt{s} - 1543 + i46} + a_{ij} + b_{ij}(\sqrt{s} - 1450)$$ (48)

at $1450 \leq \sqrt{s} \leq 1650$ MeV. The unknown parameters $g_i \times g_j$, $a_{ij}$ and $b_{ij}$ are determined by the method of least squares. We obtain the values of $g_i$ from the $g_{\eta n} \times g_i$ corresponding to the $\eta n$ final state amplitudes. Their absolute value agree fairly well with the values obtained from the pole residues and gives us confidence about our numerical evaluation of the couplings. For instance, the $\pi N$, $\eta n$ and $\pi\pi N$ branching ratios are now 24 %, 67 % and 9 % respectively.

This latter analysis allows us to determine the sign of the couplings. The signs given are relative to that of $g_{\eta n}$. It is instructive to decompose the resonance in the SU(3) representations. In fact, our result, ignoring the coupling to the $\pi\pi N$ channel, leads to

$$g_8 = -2.52 \, , \, g_{8'} = 2.62 \, , \, g_{10} = 0.43 \, , \, g_{27} = -0.47$$ (49)

and tells us that the $N^*(1535)$ resonance is almost an equal weight mixture of the R-parity even SU(3) octet 8 and the R-parity odd SU(3) octet 8’. It would be interesting to compare these results with the results from other models or lattice QCD simulations.
5 Conclusion

We have studied the S-wave $\pi N$ scattering, together with that of coupled channels, in a chiral unitary model in the region of center of mass energies from threshold to 1600 MeV. We calculated the T matrix using the Bethe-Salpeter equation in the eight coupled channels including six meson-baryon channels and two $\pi\pi N$ channels. We took the transition potentials between the meson-baryon systems from the lowest order chiral Lagrangian and improved them taking into account the vector meson dominance hypothesis. Then we introduced the appropriate $\pi N \leftrightarrow \pi\pi N$ transition potentials which influence both the elastic scattering and the pion production processes. In the present model the renormalization due to higher order contributions is included by means of subtraction constants in the real part of the propagators of the two or three-body systems, which are taken as free parameters and determined through comparison with the T matrix of the data analysis. The imaginary part of the meson-baryon or $\pi\pi N$ propagators is fixed and ensures unitarity in the S matrix. A realistic T matrix is obtained with a few free parameters for energies up to 1600 MeV. The phase-shifts and the inelasticities are well reproduced in both isospin $1/2$ and $3/2$. We find that the correction of the chiral coefficient and the $\pi\pi N$ channels are important to obtain an accurate T matrix, especially in isospin $3/2$. Our analysis allowed us to determine the S-wave amplitudes for $\pi N \rightarrow \pi\pi N$ and we found that the isospin $3/2$ $\pi N \leftrightarrow \pi\pi N$ amplitude is different from the two previous empirical ones.

The resonance $N^*(1535)$ is generated dynamically and qualifies as a quasi bound state of meson and baryon. The corresponding pole is seen in the T matrix on the complex plane. We calculate the total and partial decay width of the resonance. The total width obtained, about 80 MeV, is smaller than the PDG estimation, but agrees with the new data from BEPC. Also the large $\eta n$ branching ratio observed in the data is reproduced.

The present study has served to show the potential of the chiral unitary approach extending the predictions to higher energies than it would be possible with the use of $\chi PT$. Yet, we also saw that improvements in the basic information of the lowest order chiral Lagrangians to account for phenomenology of VMD are welcome. On the other hand we found mandatory the inclusion of the $\pi\pi N$ channels in order to find an accurate reproduction of the data, particularly those in the isospin $3/2$ sector. We also found that the introduction of these channels, forcing them to reproduce the inelasticities and other data, has as an indirect consequence that the $\Delta(1620)$ resonance appears then as a pole in the complex plane indicating a large mixing of this resonance with $\pi\pi N$ states. This interpretation would be consistent with the large experimental coupling of this resonance to the $\pi\pi N$ channel.

Acknowledgements

We would like to acknowledge discussions with J.C. Nácher. One of us, T. I., would like to thank J.A. Oller and A. Hosaka for useful discussions. This work has been partly supported by the Spanish Ministry of Education in the program “Estancias de Doctores y Tecnólogos Extranjeros en España”, by the DGICYT contract number BFM2000-1326 and by the EU TMR network Eurodaphne, contact no. ERBFMRX-CT98-0169.
