On Stein’s method for multivariate self-decomposable laws with finite first moment

Benjamin Arras*  Christian Houdré†

Abstract

We develop a multidimensional Stein methodology for non-degenerate self-decomposable random vectors in \( \mathbb{R}^d \) having finite first moment. Building on previous univariate findings, we solve an integro-partial differential Stein equation by a mixture of semigroup and Fourier analytic methods. Then, under a second moment assumption, we introduce a notion of Stein kernel and an associated Stein discrepancy specifically designed for infinitely divisible distributions. Combining these new tools, we obtain quantitative bounds on smooth-Wasserstein distances between a probability measure in \( \mathbb{R}^d \) and a non-degenerate self-decomposable target law with finite second moment. Finally, under an appropriate Poincaré-type inequality assumption, we investigate, via variational methods, the existence of Stein kernels. In particular, this leads to quantitative versions of classical results on characterizations of probability distributions by variational functionals.

Keywords: infinite divisibility; self-decomposability; Stein’s method; Stein’s kernel; weak limit theorems; rates of convergence; smooth Wasserstein distance.

1 Introduction

Stein’s method is a powerful device to quantify proximity in law between random variables. It has proven to be particularly useful to compute explicit rates of convergence in several limiting results of probability theory (from the standard central limit theorem to more complex paradigms satisfying some specific asymptotic behavior). Moreover, it has been successfully implemented for a large collection of one dimensional target limiting laws (see [45, 46, 13, 43] for standard references on the subject and [27] for a more recent survey). Most of these works essentially focus on the unidimensional setting...
On Stein’s method for multivariate self-decomposable laws with finite first moment

and related multidimensional results are relatively sparse in the literature. Indeed, the multidimensional Stein’s method has essentially been developed in the multivariate normal case (see e.g. [2, 22, 20, 41, 39, 11, 40, 31, 34, 42, 35]) and for invariant measures of multidimensional diffusions ([29, 21]). In particular, [21] proposes a general Stein’s method framework for target probability measures $\mu$ on $\mathbb{R}^d$, $d \geq 1$, which satisfy the following set of assumptions: $\mu$ has finite mean, is absolutely continuous with respect to the $d$-dimensional Lebesgue measure and its density is continuously differentiable with support the whole of $\mathbb{R}^d$.

Below, we introduce and develop a multidimensional Stein’s methodology for a different specific class of probability measures on $\mathbb{R}^d$, namely non-degenerate self-decomposable laws with finite first moment (see (2.4) in Section 2 for a definition). This class of probability measures, introduced by Paul Lévy in [26], is rather natural in the context of limit theorems for sum of independent summands and has been thoroughly studied in several classical books (see e.g. [24, 26, 19, 28, 38, 44]). Nevertheless, while being very classical in the context of limit theorems, no systematic Stein’s method has been carried out for multivariate non-degenerate self-decomposable distributions. (The whole class of non-degenerate self-decomposable laws with finite first moment is different, but has a non-empty intersection with the class of target probability measures analyzed in [21]. Indeed, non-degenerate self-decomposable laws with finite first moment admit a Lebesgue density, which might not be differentiable on $\mathbb{R}^d$, and whose support might be a half-space of $\mathbb{R}^d$.) Finally, many classical probability measures on $\mathbb{R}^d$ are self-decomposable (see [44, 47] and Section 3 below for some examples).

From our previous univariate work [1], the multidimensional Stein’s method we implement is a generalization of the semigroup method “à la Barbour” ([2]). Thanks to the particular structure of self-decomposable characteristic functions, this semigroup approach relies heavily on Fourier analytic tools. Moreover, the generator of the aforementioned semigroup is an integro-differential operator, reflecting the infinite divisibility of the target law, which can be seen as a direct consequence of a characterization identity originating in [23] and further developed and analyzed in [1]. The resulting Stein equation is a non-local partial differential equation and contrasts with the usual second order partial differential equations associated with the multivariate Gaussian distribution or with the invariant measures of Itô diffusions.

Our methodology is then applied to quantify proximity, in smooth Wasserstein distances of order 1 and 2, between an appropriate probability measure on $\mathbb{R}^d$ and a non-degenerate self-decomposable laws with finite second moment. Key quantities used in our analysis are relevant versions of Stein kernels and of Stein discrepancies in this infinitely divisible setting (see Definition 4.1). Stein kernel and Stein discrepancy are concepts which have mostly been well developed in the Gaussian setting and have recently gained a certain momentum in connection with random matrices ([9]), Malliavin calculus ([32, 33]), functional inequalities ([25, 16]), optimal transport ([18]) and rates of convergence in multidimensional central limit theorems ([35]). In particular, [16] investigates the question of existence of a Gaussian Stein kernel for probability measures satisfying a Poincaré inequality or a converse weighted Poincaré inequality (see, e.g., [3] for a definition). Thanks to earlier work on characterizing functionals of infinitely divisible distributions [14], we introduce in the last section of the present manuscript the relevant variational setting which ensures the existence of Stein kernels and implies manageable upper bounds on the Stein discrepancy. In particular, Theorem 4.5 is a quantitative version of the characterizing results contained in [14].

Let us further describe the content of the present notes. In the next section, we introduce notations used throughout this work. In Section 3, we develop the multidimensional Stein methodology for non-degenerate self-decomposable random vector with
finite first moment, extending our univariate approach ([1]). In Section 4, we introduce an infinitely divisible version of Stein kernel (and of the Stein discrepancy) and study the existence of the latter under an appropriate version of a Poincaré inequality. We end this section by providing quantitative upper bounds on the smooth Wasserstein distance of order two in terms of Poincaré constants and the second moment of the Lévy measure of the target self-decomposable distribution. A technical appendix finishes our manuscript.

2 Notations

Throughout, let $\| \cdot \|$ and $\langle \cdot, \cdot \rangle$ be respectively the Euclidean norm and the inner product on $\mathbb{R}^d$, $d \geq 1$. Let also $S(\mathbb{R}^d)$ be the Schwartz space of infinitely differentiable rapidly decreasing real-valued functions defined on $\mathbb{R}^d$, and by $\mathcal{F}$ the Fourier transform operator given, for $f \in S(\mathbb{R}^d)$, by

$$\mathcal{F}(f) (\xi) = \int_{\mathbb{R}^d} f(x) e^{-i \langle \xi, x \rangle} dx, \quad \xi \in \mathbb{R}^d.$$ 

On $S(\mathbb{R}^d)$, the Fourier transform is an isomorphism and the following well known inversion formula holds

$$f(x) = \int_{\mathbb{R}^d} \mathcal{F}(f)(\xi) e^{i \langle \xi, x \rangle} \frac{d\xi}{(2\pi)^d}, \quad x \in \mathbb{R}^d.$$ 

Let $C_b(\mathbb{R}^d)$ be the space of bounded continuous functions on $\mathbb{R}^d$ endowed with the uniform norm $\| f \|_\infty = \sup_{x \in \mathbb{R}^d} |f(x)|$, for $f \in C_b(\mathbb{R}^d)$. For any bounded linear operator, $T$, from a Banach space $(\mathcal{X}, \| \cdot \|_\mathcal{X})$ to another Banach space $(\mathcal{Y}, \| \cdot \|_\mathcal{Y})$ the operator norm is, as usual,

$$\| T \|_{op} = \sup_{f \in \mathcal{X}, \| f \|_\mathcal{X} \neq 0} \frac{\| T(f) \|_\mathcal{Y}}{\| f \|_\mathcal{X}}.$$ (2.1)

More generally, for any $r$-multilinear form $F$ from $(\mathbb{R}^d)^r$, $r \geq 1$, to $\mathcal{R}$, the operator norm of $F$ is

$$\| F \|_{op} := \sup \{ |F(v_1, ..., v_r)| : v_j \in \mathbb{R}^d, \| v_j \| = 1, j = 1, ..., r\}. \quad (2.2)$$

Throughout, a Lévy measure is a positive Borel measure on $\mathbb{R}^d$ such that $\nu(\{0\}) = 0$ and $\int_{\mathbb{R}^d} (1 + \| u \|^2)^{\gamma} \nu(du) < +\infty$. An $\mathbb{R}^d$-valued random vector $X$ is infinitely divisible with triplet $(b, \Sigma, \nu)$ (written $X \sim ID(b, \Sigma, \nu)$), if its characteristic function $\varphi$ writes, for all $\xi \in \mathbb{R}^d$,

$$\varphi(\xi) = \exp \left( i\langle \xi, b \rangle - \frac{1}{2} \langle \Sigma \xi, \xi \rangle + \int_{\mathbb{R}^d} \left( e^{i \langle \xi, u \rangle} - 1 - i \langle \xi, u \rangle 1_D(u) \right) \nu(du) \right), \quad (2.3)$$

with $b \in \mathbb{R}^d$, $\Sigma$ a symmetric nonnegative definite $d \times d$ matrix, $\nu$ a Lévy measure on $\mathbb{R}^d$ and $D$ the closed Euclidean unit ball of $\mathbb{R}^d$. In the sequel, we are mainly interested in a subclass of infinitely divisible distributions, namely the self-decomposable laws (SD). If $\varphi$ is the characteristic function of a self-decomposable distribution, then for any $\gamma \in (0, 1)$, there exists, on $\mathbb{R}^d$, a probability measure, say $\mu_\gamma$, such that, for all $\xi \in \mathbb{R}^d$,

$$\int_{\mathbb{R}^d} e^{i \langle \xi, u \rangle} \mu_\gamma(du) = \frac{\varphi(\xi)}{\varphi(\gamma \xi)}, \quad (2.4)$$

(Recall that $\varphi(\xi) \neq 0$, for all $\xi \in \mathbb{R}^d$, e.g., see [44, Lemma 7.5]). Moreover, e.g., see [44, Theorem 15.10], the Lévy measure of a self-decomposable distribution is given, for any Borel set $B$ in $\mathbb{R}^d \setminus \{0\}$, by

$$\nu(B) = \int_{S^{d-1}} \lambda(dx) \int_0^{+\infty} 1_B(rx) k_\gamma(r) \frac{dr}{r}, \quad (2.5)$$

EJP 24 (2019), paper 29. http://www.imstat.org/ejp/
On Stein’s method for multivariate self-decomposable laws with finite first moment

with \( \lambda \) a finite positive measure on the Euclidean unit sphere \( S^{d-1} \) and \( k_r(r) \) a non-negative function (Lebesgue) measurable in \( x \in S^{d-1} \) and decreasing in \( r > 0 \) (namely, \( k_r(s) \leq k_r(r) \), for \( 0 < r \leq s \)). Thanks to [44, Remark 15.12 (iii)], since \( \nu \neq 0 \), let us assume that \( \lambda(S^{d-1}) = 1 \), that \( \int_0^{+\infty} (r^2 \wedge 1) k_r(r) dr / r \) is finite and independent of \( x \) and that \( k_r(r) \) is right-continuous in \( r > 0 \). Finally, since they satisfy the divergence condition (see e.g. [44, Theorem 27.13]), non-degenerate self-decomposable laws on \( \mathbb{R}^d \) are absolutely continuous with respect to the \( d \)-dimensional Lebesgue measure.

To end this section, let us introduce some natural distances between probability measures on \( \mathbb{R}^d \). For \( p \geq 1 \), the Wasserstein-\( p \) distance between two probability measures \( \mu_X \) and \( \mu_Y \) with finite \( p \)-th moment is

\[
W_p(\mu_X, \mu_Y) = \inf_{\Pi \in \Gamma(\mu_X, \mu_Y)} \left( \int_{\mathbb{R}^d \times \mathbb{R}^d} ||x - y||^p d\Pi(x, y) \right)^{\frac{1}{p}},
\]

(2.6)

where \( \Gamma(\mu_X, \mu_Y) \) is the collection of probability measures on \( \mathbb{R}^d \times \mathbb{R}^d \) with, respective, first and last \( d \)-dimensional marginal given by \( \mu_X \) and \( \mu_Y \). By Hölder inequality, for \( 1 \leq p \leq q \),

\[
W_p(\mu_X, \mu_Y) \leq W_q(\mu_X, \mu_Y),
\]

(2.7)

while, by duality,

\[
W_1(\mu_X, \mu_Y) = \sup_{\|h\|_{Lip} \leq 1} \|Eh(X) - Eh(Y)\|
\]

(2.8)

where \( X \sim \mu_X, Y \sim \mu_Y \) and where \( Lip \) is the space of Lipschitz functions on \( \mathbb{R}^d \) endowed with the seminorm

\[
\|h\|_{Lip} = \sup_{x \neq y \in \mathbb{R}^d} \frac{|h(x) - h(y)|}{\|x - y\|}.
\]

(2.9)

Let \( \mathbb{N}^d \) be the space of multi-indices of dimension \( d \). For any \( \alpha \in \mathbb{N}^d \), let \( |\alpha| = \sum_{i=1}^d |\alpha_i| \) and let \( D^\alpha \) be the corresponding partial derivatives operator defined on smooth enough functions \( f \), by \( D^\alpha f(x_1, ..., x_d) = \partial_{x_1}^{\alpha_1} ... \partial_{x_d}^{\alpha_d} f(x_1, ..., x_d) \), for all \( (x_1, ..., x_d) \in \mathbb{R}^d \). Next, for any \( r \)-times continuously differentiable function, \( h \), on \( \mathbb{R}^d \), viewing its \( \ell \)-th derivative \( D^\ell(h) \) as a \( \ell \)-multilinear form, 1 \( \leq \ell \leq r \), let

\[
M_\ell(h) := \sup_{x \in \mathbb{R}^d} \|D^\ell(h)(x)\|_{op} = \sup_{x \neq y} \frac{\|D^{\ell-1}(h)(x) - D^{\ell-1}(h)(y)\|_{op}}{\|x - y\|}.
\]

(2.10)

For \( r \geq 0 \), let \( \mathcal{H}_r \) be the space of bounded continuous functions defined on \( \mathbb{R}^d \) which are continuously differentiable up to (and including) the order \( r \) and such that, for any such function \( f \),

\[
\max_{0 \leq \ell \leq r} M_\ell(f) \leq 1,
\]

(2.11)

with \( M_0(f) := \sup_{x \in \mathbb{R}^d} |f(x)| \). In particular, for \( f \in \mathcal{H}_r \),

\[
\max_{\alpha \in \mathbb{N}^d, 0 \leq |\alpha| \leq r} \|D^\alpha(f)\|_{\infty} \leq 1.
\]

(2.12)

Therefore, the space \( \mathcal{H}_r \) is a subspace of the set of bounded functions which are \( r \)-times continuously differentiable on \( \mathbb{R}^d \) such that \( \|D^\alpha(f)\|_{\infty} \leq 1 \), for all \( \alpha \in \mathbb{N}^d \) with \( 0 \leq |\alpha| \leq r \). Then, the smooth Wasserstein distance of order \( r \) between two random vectors \( X \) and \( Y \) with respective law \( \mu_X \) and \( \mu_Y \) is defined by

\[
d_{W_r}(\mu_X, \mu_Y) = \sup_{h \in \mathcal{H}_r} |Eh(X) - Eh(Y)|.
\]

(2.13)
Moreover, the smooth Wasserstein distance of order \( r \geq 1 \) admits the following representation (see Lemma A.2 of the Appendix)

\[
d_W,(\mu_X, \mu_Y) = \sup_{h \in W^r_c(R^d)} |E h(X) - E h(Y)|,
\]

(2.14)

where \( W_c^\infty(R^d) \) is the space of infinitely differentiable compactly supported functions on \( R^d \). In particular, for \( p \geq 1 \) and \( r \geq 1 \)

\[
d_W,(\mu_X, \mu_Y) \leq d_W,(\mu_X, \mu_Y) \leq W_1(\mu_X, \mu_Y) \leq W_p(\mu_X, \mu_Y).
\]

(2.15)

Finally, and as usual, for two probability measures, \( \mu_1 \) and \( \mu_2 \), on \( R^d, \mu_1 \) is said to be absolutely continuous with respect to \( \mu_2 \), written \( \mu_1 << \mu_2 \), if for any Borel set, \( B \), such that \( \mu_2(B) = 0 \), then \( \mu_1(B) = 0 \).

3 Stein’s equation for SD laws via semigroup methods

Let \( X \) be a non-degenerate self-decomposable random vector in \( R^d \), without Gaussian component, and with law \( \mu_X \). By non-degenerate, we mean that the support of the law of \( X \) is not contained in some \( d-1 \) dimensional subspace of \( R^d \). Denote by \( X_i \), for \( i = 1, \ldots, d \), its coordinates and assume that \( E|X_i| < \infty \), for all \( i = 1, \ldots, d \). Its characteristic function \( \varphi \) is given, for all \( \xi \in R^d \), by

\[
\varphi(\xi) = \exp \left( i\langle \xi; E X \rangle + \int_{R^d} \left( e^{i\langle \xi; u \rangle} - 1 - i\langle u; \xi \rangle \right) \nu(du) \right)
\]

\[
= \exp \left( i\langle \xi; E X \rangle + \int_{S^{d-1} \times (0, +\infty)} \left( e^{i\langle \xi; rx \rangle} - 1 - i\langle rx; \xi \rangle \right) \frac{k_x(r)}{r} dr \lambda(dx) \right),
\]

(3.1)

where \( \nu \) is the Lévy measure, while \( k_x \) and \( \lambda \) are given in (2.5). Further, assume that, for any \( 0 < a < b < +\infty \) the functions \( k_x(\cdot) \) are such that

\[
\sup_{x \in S^{d-1}} \sup_{r \in (a,b)} k_x(r) < +\infty.
\]

(3.2)

Since the function \( k_x(\cdot) \) is a decreasing function in \( r > 0 \), the previous condition boils down to,

\[
\sup_{x \in S^{d-1}} k_x(a^+) < +\infty, \quad a > 0,
\]

where \( k_x(a^+) = \lim_{r \to a^+} k_x(r), \ x \in S^{d-1} \). In (3.2), the supremum over \( x \) in \( S^{d-1} \) has to be understood as the \( \lambda \)-essential supremum of the function \( k_x(r) \) in the \( x \) variable. In the univariate case, \( d = 1 \), the polar decomposition of the Lévy measure \( \nu \) boils down to \( \nu(du) = k(u)du/|u| \) where \( k \) is non-negative, increasing on \((0, +\infty)\) and decreasing on \((0, +\infty)\). Thus, the condition (3.2) is automatically satisfied for \( d = 1 \). For \( d \geq 2 \), the polar decomposition of the Lévy measure associated with a stable distribution of index \( \alpha \in (1, 2) \) is given by

\[
\nu(du) = \mathbf{1}_{(0, +\infty)}(r) \mathbf{1}_{S^{d-1}}(x) \frac{dr}{r^{d-1}} \lambda(dx),
\]

for some finite positive measure \( \lambda \) on the \( d \)-dimensional unit sphere (see [44, Theorem 14.3]). Then, \( k_x(r) = 1/r^\alpha \), for all \( r > 0 \), and condition (3.2) is automatically satisfied (see below for more examples). Next, define a family of operators \( (P_t^\nu)_{t \geq 0} \), for all \( f \in S(R^d) \), all \( x \in R^d \) and all \( t \geq 0 \), via

\[
P_t^\nu(f)(x) = \frac{1}{(2\pi)^d} \int_{R^d} F(f)(\xi) e^{-t(x;\xi)} \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)} d\xi.
\]

(3.3)
On Stein’s method for multivariate self-decomposable laws with finite first moment

Denoting by \((\mu_t)_{t \geq 0}\) the family of probability measures given by (2.4) with \(\gamma = e^{-t}\) and using Fourier inversion on \(S(\mathbb{R}^d)\), it follows that

\[
P_t^\mu(f)(x) = \int_{\mathbb{R}^d} f(u + e^{-t}x)\mu_t(du). \tag{3.4}
\]

For all \(t \geq 0\), the probability measure \(\mu_t\) is infinitely divisible with finite first moment and its characteristic function \(\varphi_t\) admits, for all \(\xi \in \mathbb{R}^d\), the following representation

\[
\varphi_t(\xi) = \exp \left( i\langle \xi; EX(1-e^{-t}) + \int_{S^{d-1} \times (0, +\infty)} (e^{i\langle \xi; rx \rangle} - 1 - i\langle rx; \xi \rangle) \times \frac{k_x(r) - k_x(e^{t}r)}{r} dr \lambda(dx) \right). \tag{3.5}
\]

The next lemma asserts that the family of operators \((P_t^\mu)_{t \geq 0}\) is a \(C_0\)-semigroup on the space \(L^1(\mu_X)\). Its proof is very similar to the one dimensional case (see [1, Proposition 5.1]) thanks to the polar decomposition (2.5).

**Lemma 3.1.** Let \(X\) be a non-degenerate self-decomposable random vector without Gaussian component, with law \(\mu_X\), Lévy measure \(\nu\) and such that \(E\|X\| < \infty\). Moreover, let the functions \(k_x\) given by (2.5) satisfy (3.2). Let \(\varphi\) be its characteristic function and let \((P_t^\mu)_{t \geq 0}\) be the family of operators defined by (3.3). Then, \((P_t^\mu)_{t \geq 0}\) is a \(C_0\)-semigroup on the space \(L^1(\mu_X)\) and its generator \(A\) is defined, for all \(f \in S(\mathbb{R}^d)\) and for all \(x \in \mathbb{R}^d\), by

\[
A(f)(x) = \langle EX - x; \nabla(f)(x) \rangle + \int_{\mathbb{R}^d} \langle \nabla(f)(x + u) - \nabla(f)(x); u \rangle \nu(du). \tag{3.6}
\]

**Proof of Lemma 3.1.** Let \(f \in C_0(\mathbb{R}^d)\). First, by (3.4), for all \(s, t \geq 0\) and for all \(x \in \mathbb{R}^d\),

\[
P_{s+t}^\mu(f)(x) = \int_{\mathbb{R}^d} f(u + e^{-(s+t)}x)\mu_{s+t}(du).
\]

Moreover, for all \(s, t \geq 0\),

\[
P_t^\mu \circ P_s^\mu(f)(x) = \int_{\mathbb{R}^d} P_s^\mu(f)(u + e^{-t}x)\mu_t(du) = \int_{\mathbb{R}^d \times \mathbb{R}^d} f(v + e^{-s}(u + e^{-t}x))\mu_t(du)\mu_s(dv). \tag{3.7}
\]

Let \(\psi_{s,t,x}\) be the measurable function defined by \(\psi_{s,t,x}(u, v) = v + e^{-s}(u + e^{-t}x)\), for all \(u, v \in \mathbb{R}^d \times \mathbb{R}^d\). Then, from (3.7), for all \(s, t \geq 0\) and for all \(x \in \mathbb{R}^d\),

\[
P_t^\mu \circ P_s^\mu(f)(x) = \int_{\mathbb{R}^d \times \mathbb{R}^d} f(u)(\mu_t \otimes \mu_s) \circ \psi^{-1}_{s,t,x}(du).
\]

Let us now compute the characteristic function of the probability measure \((\mu_t \otimes \mu_s) \circ \psi^{-1}_{s,t,x}\). For all \(\xi \in \mathbb{R}^d\),

\[
\int_{\mathbb{R}^d} e^{i\langle \xi; u \rangle} (\mu_t \otimes \mu_s) \circ \psi^{-1}_{s,t,x}(du) = \int_{\mathbb{R}^d \times \mathbb{R}^d} e^{i\langle \xi; \psi_{s,t,x}(u, v) \rangle} \mu_t(du) \otimes \mu_s(dv)
\]

\[
= e^{i\langle \xi; e^{-(s+t)}x \rangle} \int_{\mathbb{R}^d} e^{i\langle \xi; e^{-s}v \rangle} \mu_s(dv)
\]

\[
= e^{i\langle \xi; e^{-(s+t)}x \rangle} \varphi_s(\xi) \varphi(e^{-s} \xi)
\]

\[
= e^{i\langle \xi; e^{-(s+t)}x \rangle} \frac{\varphi(\xi)}{\varphi(e^{-(s+t)} \xi)}
\]
On Stein’s method for multivariate self-decomposable laws with finite first moment

\[
\begin{align*}
&= e^{i(\xi e^{-i(t+1)}x)} \int_{\mathbb{R}^d} e^{i(\xi u)} \mu_{s+t}(du) \\
&= \int_{\mathbb{R}^d} e^{i(\phi_{s,t}^*+u)} \mu_{s+t}(du) \\
&= \int_{\mathbb{R}^d} e^{i(\xi u)} \mu_{s+t} \circ \phi_{s,t}^*(du),
\end{align*}
\]

where \( \phi_{s,t}^*(u) = e^{-(s+t)}x + u \), for all \( x \in \mathbb{R}^d \), \( s \geq 0 \) and \( t \geq 0 \). This implies that

\[
P_t^\omega \circ P_t^\nu(f)(x) = P_{s+t}^\nu(f)(x),
\]

and so the semigroup property is verified on \( C_b(\mathbb{R}^d) \). Moreover,

\[
\int_{\mathbb{R}^d} P_t^\omega(f)(x) \mu_X(dx) = \int_{\mathbb{R}^d \times \mathbb{R}^d} f(u + e^{-t}x) \mu_2(du) \mu_X(dx).
\]

(3.8)

Setting \( \omega_t(u, x) = u + e^{-t}x \), for all \( u \in \mathbb{R}^d \) and all \( x \in \mathbb{R}^d \), (3.8) then becomes

\[
\int_{\mathbb{R}^d} P_t^\omega(f)(x) \mu_X(dx) = \int_{\mathbb{R}^d} f(v)(\mu_t \otimes \mu_X) \circ \omega_t^{-1}(dv).
\]

The characteristic function of the probability measure \( (d\mu_t \otimes d\mu_X) \circ \omega_t^{-1} \) is, for all \( \xi \in \mathbb{R}^d \),

\[
\int_{\mathbb{R}^d} e^{i(\xi v)}(\mu_t \otimes \mu_X) \circ \omega_t^{-1}(dv) = \int_{\mathbb{R}^d \times \mathbb{R}^d} e^{i(\xi \omega_t(u,x))} \mu_t(du) \mu_X(dx) \\
= \int_{\mathbb{R}^d \times \mathbb{R}^d} e^{i(\xi u + e^{-t}x)} \mu_t(du) \mu_X(dx) \\
= \phi_t(\xi) \phi(e^{-t}X) \\
= \phi(\xi).
\]

Therefore, for all \( t \in \mathbb{R}^d \),

\[
\int_{\mathbb{R}^d} P_t^\omega(f)(x) \mu_X(dx) = \int_{\mathbb{R}^d} f(x) \mu_X(dx),
\]

and so the probability measure \( \mu_X \) is invariant for the family of operators \( (P_t^\nu)_{t \geq 0} \). One can further check, by Fourier arguments, that, for all \( x \in \mathbb{R}^d \),

\[
\lim_{t \to 0^+} P_t^\nu(f)(x) = f(x), \quad \lim_{t \to +\infty} P_t^\nu(f)(x) = \int_{\mathbb{R}^d} f(x) \mu_X(dx).
\]

Next, by Jensen inequality and the invariance property,

\[
\int_{\mathbb{R}^d} |P_t^\nu(f)(x)| \mu_X(dx) \leq \int_{\mathbb{R}^d} P_t^\nu(|f|)(x) \mu_X(dx) \\
\leq \int_{\mathbb{R}^d} |f(x)| \mu_X(dx).
\]

Then, by the density of \( C_b(\mathbb{R}^d) \) in \( L^1(\mu_X) \) ([4, Corollary 4.2.2]), one can extend the family of operators \( (P_t^\nu)_{t \geq 0} \) to functions in \( L^1(\mu_X) \), and, this extension, still denoted by \( (P_t^\nu)_{t \geq 0}, \) is a \( C_0 \)-semigroup on \( L^1(\mu_X) \). To end the proof of the lemma, let us compute the generator of this semigroup on \( S(\mathbb{R}^d) \). Let \( f \in S(\mathbb{R}^d) \). By Fourier inversion, for all \( x \in \mathbb{R}^d \) and for all \( t > 0 \),

\[
\frac{1}{t} \left( P_t^\nu(f)(x) - f(x) \right) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} \mathcal{F}(f)(\xi)e^{i(\xi x)} \left( e^{i(\xi e^{-t})x} - 1 \right) \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)} d\xi.
\]

EJP 24 (2019), paper 29. http://www.imstat.org/ejp/
On Stein’s method for multivariate self-decomposable laws with finite first moment

First, for all \( x \in \mathbb{R}^d \) and for all \( \xi \in \mathbb{R}^d \),
\[
\lim_{t \to 0^+} \frac{1}{t} \left( e^{i<\xi,x>}(e^{-i} - 1) \frac{\varphi(\xi)}{\varphi(e^{-i}\xi)} - 1 \right) = -i<\xi,x> + \sum_{i=1}^d \xi_i \partial_i(\varphi)(\xi),
\]
which is a well-defined limit since \( X \) has finite first moment. Now, from the representation (3.1), for all \( \xi \in \mathbb{R}^d \),
\[
\sum_{j=1}^d \xi_j \partial_j(\varphi)(\xi) = \sum_{j=1}^d \xi_j \left( i\mathbb{E}X_j + i \int_{\mathbb{R}^d} (e^{i<\nu,x>} - 1) \nu(du) \right)
\]
\[
= i \left( \langle \xi; \mathbb{E}X \rangle + \int_{\mathbb{R}^d} \langle \xi; \nu \rangle \left( e^{i<\nu,x>} - 1 \right) \nu(du) \right).
\]

Moreover, by Lemma A.1 (ii) of the Appendix, for all \( t \in (0,1) \), \( x \in \mathbb{R}^d \) and \( \xi \in \mathbb{R}^d \),
\[
\frac{1}{t} \left| e^{i<\xi,x>}(e^{-it} - 1) \frac{\varphi(\xi)}{\varphi(e^{-it}\xi)} - 1 \right| \leq C_1||\xi||||x|| + C_2||\xi||||\mathbb{E}X|| + ||\xi||^2,
\]
for some \( C_1 > 0, C_2 > 0 \), independent of \( t, \xi \) and \( x \). Then, by dominated convergence,
\[
\lim_{t \to 0^+} \frac{1}{t} \left( P_t^\nu(f)(x) - f(x) \right) = \int_{\mathbb{R}^d} \mathcal{F}(f)(\xi) e^{i<\xi,x>} \left( -i<\xi,x> + i\langle \xi; \mathbb{E}X \rangle \right)
\]
\[
+ i \int_{\mathbb{R}^d} \langle \xi; \nu \rangle \left( e^{i<\nu,x>} - 1 \right) \nu(du) d\xi,
\]
which is equal, by standard Fourier arguments, to
\[
\lim_{t \to 0^+} \frac{1}{t} \left( P_t^\nu(f)(x) - f(x) \right) = (\nabla f)(x); \mathbb{E}X + \int_{\mathbb{R}^d} (\nabla f)(x + u) - (\nabla f)(x); u \nu(du).
\]

This concludes the proof of (3.6) and of the lemma. \( \square \)

**Remark 3.2.** The analysis performed in this paper relies heavily on the properties of the semigroup of operators \( (P_t^\nu)_{t \geq 0} \). It is, moreover, possible to build a Markov process with values in \( \mathbb{R}^d \) such that its induced semigroup corresponds to \( (P_t^\nu)_{t \geq 0} \). Indeed, for all \( t \geq 0 \), since \( P_t^\nu \) is mass conservative and is a contraction on \( L^1(\mu_X) \), [3, Proposition 1.2.3] ensures the existence of a kernel \( p_t^\nu(\cdot, \cdot) \) such that, for all \( f \in C_b(\mathbb{R}^d) \),
\[
P_t^\nu(f)(x) = \int_{\mathbb{R}^d} f(z)p_t^\nu(x,dz), \quad x \in \mathbb{R}^d.
\]

In particular, \( p_t^\nu(x,dz) = \mu_t \circ \varphi_0^{-1} \circ \varphi_0(t,x)(dz) \), for all \( t \geq 0 \) and \( x \in \mathbb{R}^d \), where \( \varphi_0(t,x)(y) = e^{-t}x + y \), for all \( y \in \mathbb{R}^d \), and where \( \mu_t \) is given by (2.4) with \( \gamma = e^{-t} \). Besides, the semigroup property of \( (P_t^\nu)_{t \geq 0} \) implies that the kernels \( (p_t^\nu(\cdot, \cdot))_{t \geq 0} \) satisfy the Chapman-Kolmogorov equation. In turn, this latter relation ensures the existence of a Markov process \( \{Z_t^x : t \geq 0\} \), such that \( Z_0^x = x, \) with \( x \in \mathbb{R}^d \) and such that, for all \( f \in C_b(\mathbb{R}^d) \),
\[
E[f(Z_t^x)] = P_t^\nu(f)(x), \quad x \in \mathbb{R}^d, \quad t \geq 0.
\]

Finally, for all \( t \geq 0 \), denoting by \( X_t \) the random vector with law \( \mu_t \), one has the representation in law
\[
Z_t^x \overset{d}{=} e^{-t}x + X_t,
\]
where \( \overset{d}{=} \) stands for equality in distribution. Based on this representation, the Markov process \( \{Z_t^x : t \geq 0\} \) can be thought of as a generalization of the classical Ornstein-Uhlenbeck process whose invariant measure is the multivariate Gaussian distribution on \( \mathbb{R}^d \) (see e.g. [3, Part I, Chapter 2, Section 2.7.1]).
On Stein’s method for multivariate self-decomposable laws with finite first moment

Let \( h \in \mathcal{H}_r \cap C_0^\infty(\mathbb{R}^d) \), for some \( r \geq 1 \). The aim of the rest of the section is to solve, for all \( x \in \mathbb{R}^d \), the following integro-partial differential equation,

\[
\langle EX - x; \nabla(f) \rangle(x) + \int_{\mathbb{R}^d} \langle \nabla(f)(x + u) - \nabla(f)(x); u \rangle \nu(du) = h(x) - \mathbb{E}h(X),
\]

(3.9)

which will serve as the fundamental equation in our Stein’s methodology for non-degenerate self-decomposable law. As done in the one-dimensional case in [1], we first introduce a potential candidate solution for this equation then study its regularity and finally prove that it actually solves the equation (3.9). The following proposition deals with the existence and the regularity of the candidate solution.

**Proposition 3.3.** Let \( X \) be a non-degenerate self-decomposable random vector in \( \mathbb{R}^d \), without Gaussian component, with law \( \mu_X \), characteristic function \( \varphi \) and such that \( \mathbb{E}\|X\| < \infty \). Moreover, let the functions \( k_z \) given by (2.5) satisfy (3.2). Let \( (P_t^\nu)_{t \geq 0} \) be the semigroup of operators obtained in Lemma 3.1. Then, for any \( h \in \mathcal{H}_2 \), the function \( f_h \) given, for all \( x \in \mathbb{R}^d \), by

\[
f_h(x) = -\int_0^{t^\infty} (P_t^\nu(h)(x) - \mathbb{E}h(X)) dt,
\]

(3.10)

is well defined and twice continuously differentiable on \( \mathbb{R}^d \). Moreover, for any \( \alpha \in \mathbb{N}^d \) such that \( |\alpha| = 1 \),

\[
\|D^\alpha(f_h)\|_\infty \leq 1,
\]

(3.11)

and, for any \( \alpha \in \mathbb{N}^d \) such that \( |\alpha| = 2 \),

\[
\|D^\alpha(f_h)\|_\infty \leq \frac{1}{2}.
\]

(3.12)

**Proof of Proposition 3.3.** Let \( h \in \mathcal{H}_2 \). By (3.4) and Theorem A.4 of the Appendix, for all \( x \in \mathbb{R}^d \),

\[
|P_t^\nu(h)(x) - \mathbb{E}h(X)| \leq \|x\|e^{-t}M_1(h) + d_{W_2}(X, X_t)
\]

\[
\leq \|x\|e^{-t} + C_d e^{-\frac{1}{2}\mathbb{E}t e^{t\|X\|^2}},
\]

and so the function

\[
f_h(x) = -\int_0^{t^\infty} (P_t^\nu(h)(x) - \mathbb{E}h(X)) dt,
\]

is well defined for all \( x \in \mathbb{R}^d \). Moreover, by (3.4) and the regularity of \( h \in \mathcal{H}_2 \), for all \( 1 \leq j \leq d \) and for all \( x \in \mathbb{R}^d \),

\[
\partial_j(f_h)(x) = -\int_0^{t^\infty} e^{-t}(P_t^\nu(\partial_j(h))(x)) dt,
\]

which implies that, for all \( 1 \leq j \leq d \) and for all \( x \in \mathbb{R}^d \),

\[
|\partial_j(f_h)(x)| \leq 1.
\]

Similarly for all \( i, j \in \{1, \ldots, d\} \) and for all \( x \in \mathbb{R}^d \),

\[
\partial^2_{ij}(f_h)(x) = -\int_0^{t^\infty} e^{-2t}(P_t^\nu(\partial^2_{ij}(h))(x)) dt,
\]

which implies that

\[
|\partial^2_{ij}(f_h)(x)| \leq \frac{1}{2},
\]

and concludes the proof of the proposition. \( \square \)
Proposition 3.4. Let $X$ be a non-degenerate self-decomposable random vector in $\mathbb{R}^d$ without Gaussian component, with law $\mu_X$, characteristic function $\varphi$, and such that $E\|X\| < \infty$. Moreover, let the function $k_x$ given by (2.5) satisfy (3.2), and let $(X_t)_{t \geq 0}$ be the collection of random vectors such that, for all $t \geq 0$, $X_t$ has law $\mu_t$ given by (2.4) with $\gamma = e^{-t}$. For each $t > 0$, let $\mu_t$ be absolutely continuous with respect to the $d$-dimensional Lebesgue measure and let its Radon-Nikodym derivative, denoted by $\gamma_t$, be continuously differentiable on $\mathbb{R}^d$ and such that, for all $1 \leq i \leq d$,

$$
\lim_{y \to \pm \infty} q_t(y) = 0, \quad \int_{\mathbb{R}^d} |\partial_i(q_t)(y)|\,dy < \infty, \quad \int_0^{+\infty} e^{-2t} \left( \int_{\mathbb{R}^d} |\partial_i(q_t)(y)|\,dy \right)\,dt < \infty.
$$

(3.13)

Let $h \in H_1$ and $(P^\nu_t)_{t \geq 0}$ be the semigroup of operators obtained in Lemma 3.1. Then, the function $f_h$ given, for all $x \in \mathbb{R}^d$, by

$$
f_h(x) = -\int_0^{+\infty} (P^\nu_t(h)(x) - Eh(X))\,dt,
$$

(3.14)

is well defined and twice continuously differentiable on $\mathbb{R}^d$. Moreover, for any $\alpha \in \mathbb{N}^d$ such that $|\alpha| = 1$

$$
\|D^\alpha(f_h)\|_\infty \leq 1,
$$

(3.15)

and, for any $\alpha \in \mathbb{N}^d$ such that $|\alpha| = 2$

$$
\|D^\alpha(f_h)\|_\infty \leq C_d.
$$

(3.16)

for some $C_d > 0$ only depending on $d$.

Proof of Proposition 3.4. Let $h \in H_1$. By (3.4) and Theorem A.4, for all $x \in \mathbb{R}^d$

$$
|P^\nu_t(h)(x) - Eh(X)| \leq \|x\|e^{-t}M_1(h) + d_W(X, X_t)
\leq \|x\|e^{-t} + Cde^{-\frac{t}{\sqrt{1+t}}},
$$

and so the function

$$
f_h(x) = -\int_0^{+\infty} (P^\nu_t(h)(x) - Eh(X))\,dt,
$$

is well defined for all $x \in \mathbb{R}^d$. Moreover, by (3.4) and the regularity of $h \in H_1$, for all $1 \leq j \leq d$ and for all $x \in \mathbb{R}^d$,

$$
\partial_j(f_h)(x) = -\int_0^{+\infty} e^{-t} (P^\nu_t(\partial_j(h))(x))\,dt,
$$

which implies that, for all $1 \leq j \leq d$ and for all $x \in \mathbb{R}^d$,

$$
|\partial_j(f_h)(x)| \leq 1.
$$

Let us fix $1 \leq i \leq d$ and $x \in \mathbb{R}^d$. By definition and an integration by parts (thanks to (3.13)),

$$
P^\nu_t(\partial_i(h))(x) = \int_{\mathbb{R}^d} \partial_i(h)(xe^{-t} + y)q_t(y)\,dy
= -\int_{\mathbb{R}^d} h(xe^{-t} + y)\partial_i(q_t)(y)\,dy.
$$
Thus, for all \(1 \leq i, j \leq d\) and \(x \in \mathbb{R}^d\),

\[
\partial_j \left( P^x_t \left( \partial_i (h) \right)(x) \right) = -e^{-t} \int_{\mathbb{R}^d} \partial_j(h)(xe^{-t} + y) \partial_i(q_t)(y) dy.
\]

This representation, together with the third condition in (3.13), ensures that \(f_h\) is twice continuously differentiable on \(\mathbb{R}^d\) and that, for all \(x \in \mathbb{R}^d\) and for all \(1 \leq i, j \leq d\),

\[
\partial_{i,j}(f_h)(x) = \int_0^{+\infty} e^{-2t} \left( \int_{\mathbb{R}^d} \partial_j(h)(xe^{-t} + y) \partial_i(q_t)(y) dy \right) dt.
\]

Finally, for all \(x \in \mathbb{R}^d\) and all \(1 \leq i, j \leq d\),

\[
|\partial_{i,j}(f_h)(x)| \leq \int_0^{+\infty} e^{-2t} \left( \int_{\mathbb{R}^d} |\partial_i(q_t)(y)| dy \right) dt < +\infty.
\]

This concludes the proof of the proposition. \(\square\)

Before showing that \(f_h\), as given in the two previous propositions, is a solution to the integro-partial differential equation

\[
\langle EX - x; \nabla(f)(x) \rangle + \int_{\mathbb{R}^d} \langle \nabla(f)(x + u) - \nabla(f)(x); u \rangle \nu(du) = h(x) - Eh(X), \quad x \in \mathbb{R}^d,
\]

for \(h\) respectively in \(H_2 \cap C_c^\infty(\mathbb{R}^d)\) and \(H_1 \cap C_c^\infty(\mathbb{R}^d)\), we provide some examples of non-degenerate self-decomposable random vectors satisfying the assumptions of the aforementioned propositions.

**Some examples**

**Rotationally invariant \(\alpha\)-stable random vector in \(\mathbb{R}^d\)**. Let \(\alpha \in (1, 2)\) and let \(X\) be a rotationally invariant \(\alpha\)-stable random vector whose law is rotationally invariant. Then, its characteristic function \(\varphi\) is, for all \(\xi \in \mathbb{R}^d\),

\[
\varphi(\xi) = \exp \left(-C_{\alpha,d} \|\xi\|^\alpha\right),
\]

for some constant \(C_{\alpha,d} > 0\) depending on \(\alpha\) and \(d\). Hence, the characteristic function of \(\mu_t\) is given, for all \(\xi \in \mathbb{R}^d\), and \(t \geq 0\) by

\[
\varphi_t(\xi) = \exp \left(-C_{\alpha,d}(1 - e^{-\alpha t})\|\xi\|^\alpha\right).
\]

Thus, for all \(t > 0\), \(\mu_t\) is absolutely continuous with respect to the Lebesgue measure and its density \(q_t\) is given for all \(x \in \mathbb{R}^d\), by the Fourier inversion formula,

\[
q_t(x) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} e^{i\langle \xi; x \rangle} \varphi_t(\xi) d\xi = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} e^{i\langle \xi; x \rangle} \exp \left(-C_{\alpha,d}(1 - e^{-\alpha t})\|\xi\|^\alpha\right) d\xi. \quad (3.17)
\]

From (3.17), it is clear that \(q_t\) is continuously differentiable on \(\mathbb{R}^d\) and that, for all \(x \in \mathbb{R}^d\) and \(1 \leq j \leq d\),

\[
\partial_j(q_t)(x) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} e^{i\langle \xi; x \rangle} (i\xi_j) \exp \left(-C_{\alpha,d}(1 - e^{-\alpha t})\|\xi\|^\alpha\right) d\xi.
\]

Moreover, the characteristic function \(\varphi_t\) is linked to the Fourier transform of the transition density of a rotationally invariant \(d\)-dimensional \(\alpha\)-stable process after the time change \(\tau = (1 - e^{-\alpha t})\). Indeed, if \((Z_{\alpha}^{\tau})_{t \geq 0}\) is a rotationally invariant \(d\)-dimensional \(\alpha\)-stable
On Stein’s method for multivariate self-decomposable laws with finite first moment

Lévy process, then its characteristic function at time $t$ is given, for all $t \geq 0$ and all $\xi \in \mathbb{R}^d$, by

$$\mathbb{E} e^{i \langle \xi; X_t \rangle} = \exp \left( -\frac{t \|\xi\|^2}{2} \right).$$

Thus, for all $\xi \in \mathbb{R}^d$ and all $t \geq 0$,

$$\varphi_t(\xi) = \mathbb{E} e^{i \langle \xi; \sqrt{2} \overline{C}_{\alpha,d}^\frac{\sqrt{\alpha-d}}{2} \tau^{\alpha}_{1-\alpha} \rangle}.$$ 

Finally, Lemma 2.2 of [15] implies that the density $q_t$ and its gradient satisfy the following inequalities, for all $x \in \mathbb{R}^d$,

$$|q_t(x)| \leq C_{\alpha,d}' \left( \frac{1}{1-e^{-\alpha}} \right) \frac{(1-e^{-\alpha})}{(1-e^{-\alpha}) + \|x\|} \left( \frac{(1-e^{-\alpha})}{(1-e^{-\alpha}) + \|x\|} \right)^{\alpha+d},$$

$$\|\nabla(q_t)(x)\| \leq C_{\alpha,d}'' \left( \frac{1}{1-e^{-\alpha}} \right) \frac{(1-e^{-\alpha})}{(1-e^{-\alpha}) + \|x\|} \left( \frac{(1-e^{-\alpha})}{(1-e^{-\alpha}) + \|x\|} \right)^{\alpha+d+1},$$

for some $C_{\alpha,d}'>0, C_{\alpha,d}''>0$, only depending on $\alpha$ and $d$. It follows that $q_t$ satisfies the conditions (3.13).

### Symmetric $\alpha$-stable random vector in $\mathbb{R}^d$.

Let $\alpha \in (1,2)$ and let $X$ be a symmetric $\alpha$-stable random vector on $\mathbb{R}^d$. By [44, Theorem 14.13], the characteristic function of $X$ is given, for all $\xi \in \mathbb{R}^d$ with $\|\xi\| \neq 0$, by

$$\varphi(\xi) = \exp \left( -\int_{S^{d-1}} |x; \xi|^\alpha \lambda_1(dx) \right) = \exp \left( -\|\xi\|^\alpha \int_{S^{d-1}} \left\langle x; \frac{\xi}{\|\xi\|} \right\rangle \lambda_1(dx) \right),$$

where $\lambda_1$ is a symmetric positive finite measure on $S^{d-1}$. Then, for all $\xi \in \mathbb{R}^d$ and all $t \geq 0$,

$$\varphi_t(\xi) = \exp \left( -\int_{S^{d-1}} |x; \xi|^\alpha \lambda_1(dx) \right) = \exp \left( -\|\xi\|^\alpha \int_{S^{d-1}} \left\langle x; \frac{\xi}{\|\xi\|} \right\rangle \lambda_1(dx) \right).$$

Moreover, let us assume that there exists $c_0>0$ such that $\int_{S^{d-1}} |x; u|^\alpha \lambda_1(dx) \geq c_0$, for any $u \in S^{d-1}$. Then, $\varphi_t$ is absolutely continuous with respect to the $d$-dimensional Lebesgue measure and its density $q_t$ is given, for all $t > 0$ and all $x \in \mathbb{R}^d$, by

$$q_t(x) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} e^{i\langle \xi; x \rangle} \varphi_t(\xi) d\xi = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} e^{i\langle \xi; x \rangle} \exp \left( -\|\xi\|^\alpha \eta_\alpha(\xi) \right) d\xi,$$

with $\eta_\alpha(\xi) = \int_{S^{d-1}} |x; \xi|^\alpha \lambda_1(dx)$. For all $t > 0$, $q_t$ is continuously differentiable on $\mathbb{R}^d$ and its partial derivative in the $j$th direction, $j \in \{1,...,d\}$, is given, for all $x \in \mathbb{R}^d$, by

$$\partial_j(q_t)(x) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} e^{i\langle \xi; x \rangle} (i\xi_j) \exp \left( -\|\xi\|^\alpha \eta_\alpha(\xi) \right) d\xi.$$

### Takano distribution I [49].

Let $\alpha \in (0, +\infty)$ and let $\mu_{\alpha,d}$ be the probability measure on $\mathbb{R}^d$ given by

$$\mu_{\alpha,d}(dx) = c_{\alpha,d} \left( 1 + \|x\|^2 \right)^{-\alpha-d/2} dx,$$

where $c_{\alpha,d} > 0$ is a normalizing constant. As shown in [49] such a probability measure is self-decomposable. Moreover, from ([49, Theorem II]), its characteristic function is given, for all $\xi \in \mathbb{R}^d$, by

$$\varphi(\xi) = \exp \left( \int_0^{+\infty} 2(2\pi)^{-d/2} \left( \int_0^{+\infty} (\sqrt{2w})^{d+2}/2 K_{(d-2)/2}(\sqrt{2w}) \right) dw \right) dv.$$
On Stein’s method for multivariate self-decomposable laws with finite first moment

\[ \times \int_{S^{d-1}} dx \int_0^w \left( e^{iux}\xi - 1 - \frac{iux\xi}{1+u^2} \right) \frac{du}{u}, \]

where \( K_{(d-2)/2} \) denotes the modified Bessel function of order \((d-2)/2\) while \( g_\alpha(w) = 2/(\pi^2w) \times 1/ \left( J_\alpha^2(\sqrt{w}) + Y_\alpha^2(\sqrt{w}) \right), w > 0, \) with \( J_\alpha \) and \( Y_\alpha \) the Bessel functions of the first kind and of the second kind, respectively (see [36, Chapter 10] for definitions of Bessel functions). Finally, the Lévy measure of \(\mu_{\alpha,d}\) is given (see [49, Representation (2) page 23]) by:

\[ \nu(du) = 2 \frac{\parallel u \parallel^d}{\parallel u \parallel^d} \left( \int_0^{+\infty} g_\alpha(2w)L_{d/2} \left( \sqrt{2w\parallel u \parallel} \right) dw \right) du, \]

where \( L_{d/2}(v) = (2\pi)^{-d/2}v^{d/2}K_{d/2}(v) \), for all \( v > 0 \), implying the following polar decomposition

\[ \nu(du) = \mathds{1}_{(0,\infty)}(r)\mathds{1}_{S^{d-1}}(x) \frac{2}{r} \left( \int_0^{+\infty} g_\alpha(2w)L_{d/2} \left( \sqrt{2wr} \right) dw \right) dr\sigma(dx), \]

where \( \sigma \) is the uniform measure on \( S^{d-1} \). Hence, the condition (3.2) is automatically satisfied. Therefore, our methodology applies as soon as \( \alpha > 1/2 \) (which ensures that \( \int_{\mathbb{R}^d} \parallel x \parallel \mu_{\alpha,d}(dx) < +\infty \)).

**Takano distribution II [48].** Let \( \mu \) be the probability measure on \( \mathbb{R}^d \) given by

\[ \mu(dx) = C \exp (-\parallel x \parallel) \, dx, \]

where \( C > 0 \) is a normalizing constant. Thanks to [48, Result 1], its characteristic function \( \varphi \) is given by

\[ \varphi(x) = \exp \left( \int_{\mathbb{R}^d} \left( e^{i\xi u} - 1 \right) \frac{M(\parallel u \parallel)}{\parallel u \parallel^d} \, du \right), \quad \xi \in \mathbb{R}^d, \]

where \( M(w) = (2\pi)^{-d/2}(d+1)w^{d/2}K_{d/2}(w) \), for \( w > 0 \). Hence, \( \mu \) is an infinitely divisible probability measure on \( \mathbb{R}^d \). Moreover, the function \( M \) admits the following representation (see the last formula page 64 of [48])

\[ M(w) = C_d \int_w^{+\infty} v^{d/2}K_{(d-2)/2}(v) dv, \quad w > 0, \]

which is non-negative and decreasing on \((0, +\infty) \) (and \( C_d > 0 \)). Thus, \( \mu \) is self-decomposable and its Lévy measure admits the following polar decomposition

\[ \nu(du) = \mathds{1}_{(0,\infty)}(r)\mathds{1}_{S^{d-1}}(x) \frac{M(r)}{r} \, dr\sigma(dx), \]

where \( \sigma \) is the uniform measure on the Euclidean unit sphere. Finally, the associated functions \( k_x \) satisfy (3.2) and the probability measure \( \mu \) admits finite moments of any orders.

**Multivariate gamma distribution.** Let \( (\alpha_1, \ldots, \alpha_d) \in (0, +\infty)^d \) and let \( X = (X_1, \ldots, X_d) \) be a random vector whose independent coordinates are distributed according to gamma laws with parameters \((\alpha_i, 1)\), \( 1 \leq i \leq d \). The characteristic function of \( X \) is given by

\[ \varphi(x) = \prod_{j=1}^d (1 - i\xi_j)^{-\alpha_j}, \quad \xi \in \mathbb{R}^d. \]
On Stein’s method for multivariate self-decomposable laws with finite first moment

For any \( b > 1 \), there exists a probability measure \( \mu_b \), such that, \( \varphi(\xi) = \varphi(\xi/b)\mu_b(\xi) \), for all \( \xi \in \mathbb{R}^d \). Indeed, take \( \rho_b = \rho_{1,b} \otimes \cdots \otimes \rho_{d,b} \), where, for any \( 1 \leq j \leq d \), \( \rho_{j,b} \) is defined, for all \( \xi_j \in \mathbb{R} \), by

\[
\int_{\mathbb{R}} e^{i\xi_j x} \rho_{j,b}(dx) = \frac{(1 - i\xi_j)^{-\alpha_j}}{(1 - i\xi/b)^{-\alpha_j}}.
\]

Therefore, our methodology applies to these multivariate gamma distributions. Moreover, let \( \varphi \) be the function given by Proposition 3.3. Then, for all \( \xi \in \mathbb{R}^d \) and all \( t > 0 \),

\[
e^{-t} \sum_{j=1}^d \alpha_j \leq \left| \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)} \right| \leq 1.
\]

Other types of self-decomposable multivariate gamma distributions have been considered in the literature. In particular, [37] considers a class of infinitely divisible multivariate gamma distributions with Lévy measure having the following polar decomposition,

\[
\nu(du) = \mathbb{1}_{(0, +\infty)}(r)\mathbb{1}_{S_{d-1}}(x)\alpha \frac{\exp(-\beta r)}{r} dr \lambda(dx),
\]

where \( \alpha, \beta \) are positive reals and \( \lambda \) is a finite positive measure on the \( d \)-dimensional Euclidean unit sphere. Therefore, \( k_x(r) = \alpha e^{-\beta r}, r > 0 \) and so (3.2) is again satisfied. Moreover, such infinitely divisible multivariate gamma distributions are self-decomposable and admit absolute moment of any orders.

Another way to build probability measures on \( \mathbb{R}^d \) which are self-decomposable is through mixtures. For example, thanks to [50, Corollary p. 40], the mixture of a \( d \)-multivariate normal distribution, \( \mathcal{N}(m, \Gamma_d), m \in \mathbb{R}^d \), and of a generalized gamma convolution \( \Gamma \) (see, [5] for a definition) is self-decomposable.

Finally, let us explain how one can build an example of a self-decomposable distribution for which the \( k_x \) function defined in (2.5) does not satisfy the condition (3.2). Let \( d = 2 \) and let \( \sigma \) be the uniform measure on the circle. Let \( \alpha \in (1, 2) \) and let \( \beta \) be a positive function defined on \( S^1 \), measurable on \( S^1 \) and such that

\[
\int_{S^1} \beta(x)\sigma(dx) < +\infty, \quad \sup_{x \in S^1} \beta(x) = +\infty.
\]

Then, the self-decomposable distribution whose Lévy measure is given through the polar decomposition

\[
\nu(du) = \mathbb{1}_{(0, +\infty)}(r)\mathbb{1}_{S^1}(x)\frac{\beta(x)}{r^{\alpha+1}} dr \sigma(dx),
\]

has finite first moment but does not satisfy the condition (3.2) since then \( k_x(r) = \beta(x)/r^\alpha \), for all \( r > 0 \) and a.e. \( x \in S^1 \).

Let us next return to the integro-partial differential equation (3.9) and solve it for any \( h \in \mathcal{H}_2 \cap C_0^\infty(\mathbb{R}^d) \). In fact, under the assumption of Proposition 3.4, it is possible to solve, \emph{mutatis mutandis}, the Stein equation (3.9) for \( h \in \mathcal{H}_1 \cap C_0^\infty(\mathbb{R}^d) \).

\textbf{Proposition 3.5.} Let \( X \) be a non-degenerate self-decomposable random vector in \( \mathbb{R}^d \) without Gaussian component, with law \( \mu_X \), with Lévy measure \( \nu \) and such that \( E\|X\| < \infty \). Moreover, let the functions \( k_x \) given by (2.5) satisfy (3.2). Let \( h \in \mathcal{H}_2 \cap C_0^\infty(\mathbb{R}^d) \) and let \( f_h \) be the function given by Proposition 3.3. Then, for all \( x \in \mathbb{R}^d \),

\[
\langle EX - x; \nabla(f_h)(x) \rangle + \int_{\mathbb{R}^d} \langle \nabla(f_h)(x + u) - \nabla(f_h)(x); u \rangle \nu(du) = h(x) - Eh(X).
\]
On Stein’s method for multivariate self-decomposable laws with finite first moment

Proof of Proposition 3.5. Let \( h \in \mathcal{H}_2 \cap \mathcal{C}_c^\infty(\mathbb{R}^d) \), let \( f_h \) be given by (3.10) and let \( \hat{h} = h - E_h(X) \).
Step 1: Let us prove that for all \( t > 0 \) and all \( x \in \mathbb{R}^d \),

\[
\frac{d}{dt} (P^\nu_t(h)(x)) = \mathcal{A}(P^\nu_t(h))(x).
\]

(3.18)

Since \( h \in \mathcal{C}_c^\infty(\mathbb{R}^d) \), by Fourier inversion, for all \( t > 0 \) and for all \( x \in \mathbb{R}^d \),

\[
P^\nu_t(h)(x) = \int_{\mathbb{R}^d} F(h)(\xi)e^{ix\cdot\xi} \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)} e^{-t} \frac{d\xi}{(2\pi)^d},
\]

which will be used to compute \( d(P^\nu_t(h)(x))/dt \). First, note that, for all \( x \in \mathbb{R}^d, \xi \in \mathbb{R}^d \) and \( t > 0 \),

\[
\frac{d}{dt} \left( e^{ix\cdot\xi} \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)} \right) = -ie^{-t}\langle x; e^{ix\cdot\xi} \rangle \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)} + e^{ix\cdot\xi} \varphi(\xi)e^{-t} \left( \sum_{j=1}^d \partial_j(\varphi)(e^{-t}\xi) \right)
\]

\[
= e^{ix\cdot\xi} \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)} \left( -ie^{-t}\langle x; \xi \rangle + e^{-t} \sum_{j=1}^d \partial_j(\varphi)(e^{-t}\xi) \right)
\]

\[
= e^{ix\cdot\xi} \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)} e^{-t} \left( \langle EX - x; \xi \rangle + \int_{\mathbb{R}^d} \langle u; \xi \rangle (e^{i\langle u,e^{-t}\xi \rangle} - 1) \nu(du) \right).
\]

Moreover, for all \( x \in \mathbb{R}^d, \) for all \( \xi \in \mathbb{R}^d \) and all \( t > 0 \),

\[
\left| \frac{d}{dt} \left( e^{ix\cdot\xi} \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)} \right) \right| \leq e^{-t} \left( \|EX - x\|\|\xi\| + \|\xi\|^2 e^{-t} \int_{\|u\| \leq 1} \|u\|^2 \nu(du) \right.
\]

\[
+ 2\|\xi\| \int_{\|u\| > 1} \|u\| \nu(du) \right)
\]

\[
\leq \left( \|EX - x\|\|\xi\| + \|\xi\|^2 \left( \int_{\|u\| \leq 1} \|u\|^2 \nu(du) \right.
\]

\[
+ 2\|\xi\| \int_{\|u\| > 1} \|u\| \nu(du) \right).
\]

Hence,

\[
\frac{d}{dt} (P^\nu_t(h)(x)) = \int_{\mathbb{R}^d} F(h)(\xi)e^{ix\cdot\xi} \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)} e^{-t} \left( \langle EX - x; \xi \rangle + \int_{\mathbb{R}^d} \langle u; \xi \rangle (e^{i\langle u,e^{-t}\xi \rangle} - 1) \nu(du) \right) \frac{d\xi}{(2\pi)^d}.
\]

To conclude the first step, let us precisely compute the right-hand side of the previous equality. First,

\[
\int_{\mathbb{R}^d} F(h)(\xi)e^{ix\cdot\xi} \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)} e^{-t} \langle EX - x; \xi \rangle \frac{d\xi}{(2\pi)^d} = \langle EX - x; e^{-t}\mathcal{A}(\hat{h})(x) \rangle
\]

\[
= \langle EX - x; \nabla (P^\nu_t(h))(x) \rangle.
\]

Using \( e^{-t}\mathcal{A}(\partial_j(h))(x) = \partial_j(P^\nu_t(h))(x) \), for all \( t \geq 0 \), all \( x \in \mathbb{R}^d \) and all \( 1 \leq j \leq d \). Moreover, by Fubini Theorem and Fourier arguments,
On Stein’s method for multivariate self-decomposable laws with finite first moment

\[
(I) := \int_{\mathbb{R}^d} F(h)(\xi) e^{i\langle x; \xi \rangle} \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)} e^{-t} \left( \int_{\mathbb{R}^d} \langle u; \xi \rangle (e^{i\langle u; e^{-t}\xi \rangle} - 1) \bigtriangledown \varphi(\xi) \right) d\xi
\]

\[
= d \int_{\mathbb{R}^d} \left( \int_{\mathbb{R}^d} u_j \left( F(\partial_j(h)(x+e^{-t}u)) - F(\partial_j(h)(x)) \right) \bigtriangledown \varphi(\xi) \right) d\xi
\]

\[
= d \int_{\mathbb{R}^d} u_j e^{-t} (P_t^\nu(h)(x+u) - P_t^\nu(h)(x)) \bigtriangledown \varphi(\xi) \right) d\xi
\]

\[
= \int_{\mathbb{R}^d} \langle u; \bigtriangledown (P_t^\nu(h)(x+u) - P_t^\nu(h)(x)) \bigtriangledown \varphi(\xi) \right) d\xi
\]

Thus, for all \( x \in \mathbb{R}^d \) and all \( t > 0 \),

\[
\frac{d}{dt} (P_t^\nu(h)) (x) = A(P_t^\nu(h))(x),
\]

which gives (3.18) and finishes the proof of the first step.

**Step 2**: Let \( 0 < b < +\infty \). Integrating out the equality (3.18) gives,

\[
P_b^\nu(h)(x) - h(x) = \int_0^b A(P_t^\nu(h))(x)dt,
\]

then, letting \( b \to +\infty \) and using Lemma 3.1 lead to:

\[
\lim_{b\to+\infty} (P_b^\nu(h)(x) - h(x)) = -\hat{h}(x), \quad x \in \mathbb{R}^d.
\]

Next, let us show that \( \int_0^{+\infty} |A(P_t^\nu(h))(x)| dt < +\infty \), for all \( x \in \mathbb{R}^d \). To do so, we need to estimate the quantities \( \|\bigtriangledown (P_t^\nu(h)(x))\| \) and \( \|\bigtriangledown (P_t^\nu(h)(x+u) - P_t^\nu(h)(x))\| \), for all \( x \in \mathbb{R}^d \), all \( u \in \mathbb{R}^d \), and all \( t \geq 0 \). Since \( \partial_j (P_t^\nu(h)) (x) = e^{-t} P_t^\nu(\partial_j(h))(x) \) and since \( h \in H_2 \),

\[
\|\bigtriangledown (P_t^\nu(h)(x))\| \leq \sqrt{d}e^{-t},
\]

\[
\|\bigtriangledown (P_t^\nu(h)(x+u) - P_t^\nu(h)(x))\| \leq \sqrt{d}e^{-t} 1_{\|u\| \geq 1} + \sqrt{d}e^{-t} 1_{\|u\| \leq 1}.
\]

Then, by the very definitions of \( A \) and of \( P_t^\nu \) and standard inequalities, for all \( x \in \mathbb{R}^d \), and all \( t \geq 0 \),

\[
|A(P_t^\nu(h))(x)| \leq \sqrt{d}e^{-t} \left( \|EX - x\| + \int_{\|u\| \leq 1} \|u\|^2 \nu(du) + \int_{\|u\| \geq 1} \|u\| \nu(du) \right),
\]

which implies that \( \int_0^{+\infty} |A(P_t^\nu(h))(x)| dt < +\infty \), for all \( x \in \mathbb{R}^d \). Moreover, \( A(P_t^\nu(h))(x) = A(P_t^\nu(\hat{h}))(x) \), thus, for all \( x \in \mathbb{R}^d \),

\[
-\hat{h}(x) = \int_0^{+\infty} A(P_t^\nu(\hat{h}))(x)dt.
\]

To conclude, one needs to prove that, for all \( x \in \mathbb{R}^d \),

\[
\int_0^{+\infty} A(P_t^\nu(\hat{h}))(x)dt = A\left( \int_0^{+\infty} P_t^\nu(\hat{h})(x)dt \right) = -A(f_{\nu})(x).
\]

But, this follows from standard arguments as well as from Proposition 3.3. \( \square \)
On Stein’s method for multivariate self-decomposable laws with finite first moment

We end this section by proving regularity estimates for the solution \( f_h \) of the Stein equation under the assumptions of Proposition 3.3. Similar estimates hold true under the assumptions of Proposition 3.4. In particular, under these latter assumptions, it is sufficient to have \( h \in \mathcal{H}_1 \) to obtain a bound on \( M_2(f_h) \), and this is in line with the Gaussian case (see [39, 11, 31]).

**Proposition 3.6.** Let \( X \) be a non-degenerate self-decomposable random vector in \( \mathbb{R}^d \) without Gaussian component, with law \( \mu_X \), characteristic function \( \varphi \) and such that \( \mathbb{E}\|X\| < \infty \). Moreover, let the functions \( k_x \) given by (2.5) satisfy (3.2). Let \( h \in \mathcal{H}_2 \) and \( (P^\nu_t)_{t \geq 0} \) be the semigroup of operators obtained in Lemma 3.1. Then, \( f_h \) given, for all \( x \in \mathbb{R}^d \), by

\[
  f_h(x) = - \int_0^{+\infty} (P^\nu_t(h)(x) - \mathbb{E}h(X)) dt,
\]

is such that

\[
  M_1(f_h) \leq 1, \quad M_2(f_h) \leq \frac{1}{2}.
\]

**Proof of Proposition 3.6.** By definition,

\[
  M_1(f_h) = \sup_{x \in \mathbb{R}^d} \|\nabla(f_h)(x)\|_{op}.
\]

Let \( u \in \mathbb{R}^d \) with \( \|u\| = 1 \). Then, by the commutation relation \( \nabla(P^\nu_t(h))(x) = e^{-t} P^\nu_t(\nabla(h))(x) \), for all \( x \in \mathbb{R}^d \) and for all \( t \geq 0 \), one has

\[
  \nabla(f_h)(x) = - \int_0^{+\infty} e^{-t} P^\nu_t(\nabla(h))(x) dt, \quad x \in \mathbb{R}^d.
\]

Hence, for all \( x \in \mathbb{R}^d \),

\[
  \langle \nabla(f_h)(x); u \rangle = - \int_0^{+\infty} e^{-t} P^\nu_t (\langle \nabla(h); u \rangle) (x) dt,
\]

which readily implies that \( M_1(f_h) \leq M_1(h) \leq 1 \) since \( h \in \mathcal{H}_2 \). The bound on \( M_2(f_h) \) follows similarly using the commutation relation twice and the fact that \( h \in \mathcal{H}_2 \).

\( \square \)

### 4 Stein kernels for SD laws with finite second moment

In the Gaussian setting, a major finding in the context of Stein’s method is the introduction of the notion of Stein kernel (see e.g. [46, 7, 8, 9, 32, 10, 33, 35, 25, 16]). Recall that \( \gamma_d \), a centered Gaussian measure on \( \mathbb{R}^d \), satisfies the following integration by parts formula,

\[
  \int_{\mathbb{R}^d} \langle f(x); \gamma_d(dx) \rangle = \int_{\mathbb{R}^d} \text{div}(f(x)) \gamma_d(dx),
\]

for all smooth enough, \( \mathbb{R}^d \)-valued function \( f = (f_1, \ldots, f_d) \) and where \( \text{div}(f(x)) = \sum_{j=1}^d \partial_j(f_j)(x) \). For a centered probability measure \( \rho \) on \( \mathbb{R}^d \), the Gaussian Stein kernel of \( \rho \) is the measurable function \( \tau_\rho \) from \( \mathbb{R}^d \) to \( \mathcal{M}_{d \times d}(\mathbb{R}) \), the space of \( d \times d \) real matrices, such that, for all smooth enough \( \mathbb{R}^d \)-valued function \( f \),

\[
  \int_{\mathbb{R}^d} \langle f(x); \rho(dx) \rangle = \int_{\mathbb{R}^d} \langle \tau_\rho(x); \nabla(f)(x) \rangle_{HS} \rho(dx),
\]

where \( \langle A; B \rangle_{HS} = \text{Tr}(A^t B) \), for \( A, B \in \mathcal{M}_{d \times d}(\mathbb{R}) \). Recall, also from the previous section, that a non-degenerate self-decomposable random vector \( X \) without Gaussian component,
On Stein’s method for multivariate self-decomposable laws with finite first moment

with law $\mu_X$ and with finite first moment satisfies, for $f$ smooth enough, the following characterizing equation:

$$\int_{\mathbb{R}^d} (x - E X; \nabla(f)(x)) \mu_X(dx) = \int_{\mathbb{R}^d} \left( \int_{\mathbb{R}^d} (\nabla(f)(x + u) - \nabla(f)(x); u) \nu(du) \right) \mu_X(dx).$$

Then, quite naturally, in the infinitely divisible framework, let us introduce the following definitions of Stein kernels and of the Stein discrepancy.

**Definition 4.1.** Let $X$ be a centered non-degenerate infinitely divisible random vector without Gaussian component, with law $\mu_X$, Lévy measure $\nu$ and such that $E\|X\|^2 < \infty$. Let $Y$ be a centered random vector with law $\mu_Y$ and such that $E\|Y\|^2 < \infty$. A Stein kernel of $Y$ with respect to $X$ is a measurable function $\tau_Y$ from $\mathbb{R}^d$ to $\mathbb{R}^d$ such that,

$$\int_{\mathbb{R}^d} \langle y; f(y) \rangle \mu_Y(dy) = \int_{\mathbb{R}^d} \left( \int_{\mathbb{R}^d} (f(y + u) - f(y); \tau_Y(y + u) - \tau_Y(y)) \nu(du) \right) \mu_Y(dy),$$

for all $\mathbb{R}^d$-valued test function $f$ for which both sides of the previous equality are well defined. The Stein’s discrepancy of $\mu_Y$ with respect to $\mu_X$ is given by

$$S(\mu_Y||\mu_X) = \inf \left( \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \|\tau_Y(y + u) - \tau_Y(y) - u\|^2 \nu(du) \mu_Y(dy) \right)^{1/2},$$

where the infimum is taken over all Stein kernels of $Y$ with respect to $X$, and is equal to $+\infty$ if no such Stein kernel exists.

The next result ensures that the Stein’s discrepancy provides a good control of some classical metrics between probability measures on $\mathbb{R}^d$.

**Theorem 4.2.** Let $X$ be a centered non-degenerate self-decomposable random vector without Gaussian component, with law $\mu_X$, Lévy measure $\nu$, such that $E\|X\|^2 < +\infty$ and let also the functions $k_x$ given by (2.5) satisfy (3.2). Let $Y$ be a centered non-degenerate random vector with law $\mu_Y$, such that $E\|Y\|^2 < +\infty$, and for which a Stein kernel with respect to $X$ exists. Then,

$$d_{W_2}(\mu_X, \mu_Y) \leq \frac{1}{2} \left( \int_{\mathbb{R}^d} \|u\|^2 \nu(du) \right)^{1/2} S(\mu_Y||\mu_X).$$

**Proof of Theorem 4.2.** Let $h \in H_2 \cap C^\infty_c(\mathbb{R}^d)$. By Proposition 3.5, $f_h$ is a solution to,

$$-(x; \nabla(f_h)(x)) + \int_{\mathbb{R}^d} \langle \nabla(f_h)(x + u) - \nabla(f_h)(x); u \rangle \nu(du) = h(x) - Eh(X), \quad x \in \mathbb{R}^d,$$

and thus,

$$E \left( -(Y; \nabla(f_h)(Y)) + \int_{\mathbb{R}^d} \langle \nabla(f_h)(Y + u) - \nabla(f_h)(Y); u \rangle \nu(du) \right) = Eh(Y) - Eh(X).$$

Now, since $Y$ admits a Stein kernel with respect to $X$,

$$Eh(Y) - Eh(X) = E \left( \int_{\mathbb{R}^d} \langle \nabla(f_h)(Y + u) - \nabla(f_h)(Y); u - \tau_Y(Y + u) + \tau_Y(Y) \rangle \nu(du) \right).$$

Taking the absolute values and applying the Cauchy-Schwarz inequality,

$$|Eh(Y) - Eh(X)| \leq E \int_{\mathbb{R}^d} \|\nabla(f_h)(Y + u) - \nabla(f_h)(Y)\| \|\tau_Y(Y + u) - \tau_Y(Y) - u\| \nu(du).$$
On Stein’s method for multivariate self-decomposable laws with finite first moment

Now, by the very definition of $M_2(f_h)$ and by the Cauchy-Schwarz inequality (applied twice), the following bound holds true

$$|Eh(Y) - Eh(X)| \leq M_2(f_h) \sqrt{ \int_{R^d} \|u\|^2 \nu(du)} \sqrt{E \int_{R^d} \|\tau_Y(Y + u) - \tau_Y(Y) - u\|^2 \nu(du)}.$$ 

To conclude use the definition of the Stein discrepancy and Proposition 3.6.

In the sequel, we wish to discuss sufficient conditions for the existence of Stein kernels as defined above. For this purpose, let us recall, in connection with Poincaré type inequalities in an infinitely divisible setting, some definitions and results from [12, 14]. First, if $X$ is a non-degenerate infinitely divisible random vector in $R^d$ without Gaussian component, with law $\mu_X$ and with Lévy measure $\nu$ and if $f : R^d \to R$ is such that $Ef(X)^2 + E\int_{R^d} |f(X + u) - f(X)|^2 \nu(du) < +\infty$, then [12, Theorem 4.1] gives

$$\text{Var}(f(X)) \leq E \int_{R^d} |f(X + u) - f(X)|^2 \nu(du).$$ (4.1) 

Further, if $Y$ is a centered non-degenerate random vector in $R^d$ such that $E\|Y\|^2 < +\infty$, if $\nu$ is a Lévy measure in $R^d$ such that $\int_{R^d} \|u\|^2 \nu(du) < +\infty$ and if $H_Y$ is the space of real valued functions $f$ on $R^d$ such that $Ef(Y)^2 < +\infty$ and $0 < E \int_{R^d} |f(Y + u) - f(Y)|^2 \nu(du) < +\infty$, then the Poincaré constant $U(Y, \nu)$ defined as

$$U(Y, \nu) = \sup_{f \in H_Y} \frac{\text{Var}(f(Y))}{E \int_{R^d} |f(Y + u) - f(Y)|^2 \nu(du)},$$ (4.2) 

characterizes the proximity in law of $Y$ to a centered infinitely divisible random vector with finite second moment and Lévy measure $\nu$. Indeed, [14, Theorem 2.1] proves the following: if $E\|Y\|^2 = \int_{R^d} \|u\|^2 \nu(du)$, for all $1 \leq i \leq d$, then $U(Y, \nu) \geq 1$ and $U(Y, \nu) = 1$ if and only if the characteristic function of $Y$ is given by

$$\varphi_Y(\xi) = \exp \left( \int_{R^d} \left( e^{\langle \xi; u \rangle} - 1 - i \langle \xi; u \rangle \right) \nu(du) \right), \quad \xi \in R^d,$$

i.e., if and only if $Y \sim ID(b, 0, \nu)$, with $b = -\int_{\|u\| \geq 1} \|u\|^2 \nu(du)$.

In the Gaussian case, the existence of a Stein kernel for multivariate distributions has been investigated with the help of variational methods. Indeed, in [16], under a spectral gap assumption, the existence of a Gaussian Stein kernel has been ensured thanks to the classical Lax-Milgram Theorem. Thus, in view of (4.2) and the associated characterization, it is natural to introduce the following variational setting: let $Y$ be a centered non-degenerate random vector with finite second moment and with law $\mu_Y$ and let $\nu$ be a Lévy measure on $R^d$ such that $\int_{\|u\| \geq 1} \|u\|^2 \nu(du) < +\infty$. Moreover, assume that $\nu \ast \mu_Y << \mu_Y$, with $\nu \ast \mu_Y$ denoting the convolution of the two positive measures $\nu$ and $\mu_Y$. Now, let $H_{\nu}(\mu_Y)$ be the vector space of Borel measurable $R^d$-valued functions on $R^d$ such that $\int_{R^d} \|f(y)\|^2 \mu_Y(dy) < +\infty$ and $\int_{R^d \times R^d} \|f(y + u) - f(y)\|^2 \nu(du) \mu_Y(dy) < +\infty$ and let $H_{\nu, 0}(\mu_Y)$ be the subspace of $H_{\nu}(\mu_Y)$ such that $Ef(Y) = 0$. (Two functions $f$ and $g$ of $H_{\nu}(\mu_Y)$ are identified as soon as $f = g$, $\mu_Y$-almost everywhere.) Then, let us assume that $Y$ satisfies a Poincaré inequality of the following type: there exists a positive and finite constant $U_Y$ such that, for all $f \in H_{\nu}(\mu_Y)$

$$E\|f(Y) - Ef(Y)\|^2 \leq U_Y E \int_{R^d} \|f(Y + u) - f(Y)\|^2 \nu(du).$$ (4.3) 

In particular, note that if $Y$ is such that $U(Y, \nu) < +\infty$ in (4.2), then, for all $f \in H_{\nu}(\mu_Y)$ such that $f_j \in H_{\nu, 1}$, $1 \leq j \leq d$,

$$E\|f_j(Y) - Ef_j(Y)\|^2 \leq U(Y, \nu) E \int_{R^d} \|f_j(Y + u) - f_j(Y)\|^2 \nu(du),$$

$$E\|f(Y) - Ef(Y)\|^2 \leq U_Y E \int_{R^d} \|f(Y + u) - f(Y)\|^2 \nu(du).$$ (4.3)
On Stein’s method for multivariate self-decomposable laws with finite first moment

so that $Y$ satisfies (4.3) with $U_Y = U(Y, \nu)$.

Moreover, let $A$ be the bilinear functional defined, for all test functions $f$ and $g$, by

$$A(f, g) = \mathbb{E} \int_{\mathbb{R}^d} (f(Y + u) - f(Y); g(Y + u) - g(Y)) \nu(du), \quad (4.4)$$

and let $L$ be the linear functional defined, for all test functions $f$, by

$$L(f) = \mathbb{E}(Y; f(Y)). \quad (4.5)$$

Before solving the variational problem associated with $A$, $L$ and $H_\nu(\mu_Y)$, we need the following technical lemma.

**Lemma 4.3.** The vector space $H_\nu(\mu_Y)$ endowed with the bilinear functional

$$\langle f; g \rangle_{H_\nu(\mu_Y)} = \mathbb{E}(f(Y); g(Y)) + A(f, g), \quad (4.6)$$

is a Hilbert space. Moreover, $A$, defined by (4.4), is continuous on $H_\nu(\mu_Y) \times H_\nu(\mu_Y)$, coercive on $H_{\nu,0}(\mu_Y)$ while, $L$, defined by (4.5), is continuous on $H_\nu(\mu_Y)$.

**Proof of Lemma 4.3.** First, it is clear that the bilinear symmetric functional $\langle \cdot; \cdot \rangle_{H_\nu(\mu_Y)}$ is an inner product on $H_\nu(\mu_Y)$. Then, let $\| \cdot \|_{H_\nu(\mu_Y)}$ be the induced norm defined via $\|f\|_{H_\nu(\mu_Y)}^2 = \mathbb{E}(f(Y))^2 + A(f, f)$, for all $f \in H_\nu(\mu_Y)$. Let us prove that $H_\nu(\mu_Y)$ endowed with this norm is complete. Let $(f_n)_{n \geq 1}$ be a Cauchy sequence in $H_\nu(\mu_Y)$. Therefore $(f_n)_{n \geq 1}$ is a Cauchy sequence in $L^2(\mu_Y)$, and there exists $f \in L^2(\mu_Y)$ such that $f_n \to f$, as $n \to +\infty$ in $L^2(\mu_Y)$. Now, pick a subsequence $(f_{n_k})_{k \geq 1}$ such that $f_{n_k} \to f$, $\mu_Y$-almost everywhere, as $k \to +\infty$. Fatou’s lemma together with the assumption that $\nu \ast \mu_Y < \mu_Y$ and the fact that $(f_n)_{n \geq 1}$ is a Cauchy sequence in $H_\nu(\mu_Y)$ (thus is bounded), imply that

$$A(f, f) \leq \liminf_{k \to +\infty} A(f_{n_k}, f_{n_k}) \leq \sup_{n \geq 1} \|f_n\|_{H_\nu(\mu_Y)}^2 < +\infty. \quad (4.7)$$

Therefore, $f \in H_\nu(\mu_Y)$. Another application of Fatou’s lemma, and since $(f_n)_{n \geq 1}$ is Cauchy in $H_\nu(\mu_Y)$, shows that $f_n \to f$ in $H_\nu(\mu_Y)$. Now, by the Cauchy-Schwarz inequality, for all $f, g \in H_\nu(\mu_Y)$,

$$|A(f, g)| \leq \left( \mathbb{E} \int_{\mathbb{R}^d} \|f(Y + u) - f(Y)\|^2 \nu(du) \right)^{1/2} \left( \mathbb{E} \int_{\mathbb{R}^d} \|g(Y + u) - g(Y)\|^2 \nu(du) \right)^{1/2}$$
$$\leq \|f\|_{H_\nu(\mu_Y)} \|g\|_{H_\nu(\mu_Y)},$$

which proves that $A$ is a continuous bilinear functional on $H_\nu(\mu_Y)$. Moreover, since $Y$ satisfies (4.3), for all $f \in H_{\nu,0}(\mu_Y)$

$$A(f, f) = \mathbb{E} \int_{\mathbb{R}^d} \|f(Y + u) - f(Y)\|^2 \nu(du),$$
$$\geq \frac{1}{2} \mathbb{E} \int_{\mathbb{R}^d} \|f(Y + u) - f(Y)\|^2 \nu(du) + \frac{1}{2U_Y} \mathbb{E} \|f(Y)\|^2,$$
$$\geq C_Y \|f\|_{H_\nu(\mu_Y)}^2,$$

for $2C_Y = \min (1, 1/(U_Y)) > 0$ and so $A$ is coercive on $H_{\nu,0}(\mu_Y)$. Finally, the continuity property of the linear functional $L$ on $H_\nu(\mu_Y)$ follows from the Cauchy-Schwarz inequality, from $\mathbb{E}\|Y\|^2 < +\infty$, and from the continuous embedding $H_\nu(\mu_Y) \hookrightarrow L^2(\mu_Y)$. \hfill \Box

Note that since $H_{\nu,0}(\mu_Y)$ is a closed subspace of $H_\nu(\mu_Y)$, it is as well a Hilbert space with the inner product $\langle \cdot; \cdot \rangle_{H_\nu(\mu_Y)}$.

Based on Lemma 4.3, a direct application of the Lax-Milgram Theorem (see, e.g., [17, Theorem 1 page 297] for a precise statement as well as a proof) ensures the existence of a Stein kernel in the sense of Definition 4.1 for probability measures $\mu_Y$ satisfying the Poincaré-type inequality (4.3). This is the content of the next theorem.
On Stein’s method for multivariate self-decomposable laws with finite first moment

**Theorem 4.4.** Let $Y$ be a centered non-degenerate random vector with finite second moment and with law $\mu_Y$, let $v$ be a Lévy measure on $\mathbb{R}^d$ such that $\int_{|u|\geq 1} |u|^2 \nu(du) < +\infty$ and let $v \ast \mu_Y \ll \mu_Y$. Let $Y$ satisfy the Poincaré-type inequality (4.3) for some $0 < U_Y < +\infty$. Then, there exists a unique $\tau_Y \in H_{\nu,0}(\mu_Y)$, such that, for all $f \in H_{\nu,0}(\mu_Y)$

$$A(f, \tau_Y) = L(f).$$

Moreover,

$$E \int_{\mathbb{R}^d} \|\tau_Y(Y + u) - \tau_Y(Y)\|^2 \nu(du) \leq U_Y \|Y\|^2. \quad (4.9)$$

**Proof of Theorem 4.4.** The first part of the theorem is a direct application of the Lax-Milgram Theorem with $A$, $L$ and $H_{\nu,0}(\mu_Y)$. To obtain the inequality (4.9), note that thanks to (4.8) with $f = \tau_Y$,

$$E \int_{\mathbb{R}^d} \|\tau_Y(Y + u) - \tau_Y(Y)\|^2 \nu(du) = A(\tau_Y, \tau_Y) = L(\tau_Y) \leq \sqrt{E\|Y\|^2} \sqrt{E\|\tau_Y(Y)\|^2}. \quad (4.10)$$

Then, (4.3) applied to $f(\cdot) = \tau_Y(\cdot)$ (note that $E\tau_Y(Y) = 0$) ensures that

$$E\|\tau_Y(Y)\|^2 \leq U_Y E \int_{\mathbb{R}^d} \|\tau_Y(Y + u) - \tau_Y(Y)\|^2 \nu(du). \quad (4.11)$$

Finally, (4.10) together with (4.11) implies

$$E \int_{\mathbb{R}^d} \|\tau_Y(Y + u) - \tau_Y(Y)\|^2 \nu(du) \leq \sqrt{U_Y} \sqrt{E\|Y\|^2} \sqrt{E \int_{\mathbb{R}^d} \|\tau_Y(Y + u) - \tau_Y(Y)\|^2 \nu(du)},$$

which concludes the proof.

The next theorem is the main result of this section.

**Theorem 4.5.** Let $X$ be a centered non-degenerate self-decomposable random vector without Gaussian component, with law $\mu_X$, with Lévy measure $\nu$, such that $E\|X\|^2 < +\infty$ and let also the functions $k_x$ given by (2.5) satisfy (3.2). Let $Y$ be a centered non-degenerate random vector with law $\mu_Y$, with $E\|Y\|^2 < +\infty$ and such that $v \ast \mu_Y \ll \mu_Y$. Let $Y$ satisfy a Poincaré-type inequality (4.3) with $1 \leq U_Y < +\infty$. Then,

$$d_{W_2}(\mu_X, \mu_Y) \leq \frac{1}{2} \left( \int_{\mathbb{R}^d} \|u\|^2 \nu(du) \right)^{1/2} \left( U_Y E\|Y\|^2 + \int_{\mathbb{R}^d} \|u\|^2 \nu(du) - 2E\|Y\|^2 \right)^{1/2}. \quad (4.12)$$

Moreover, if $E\|Y\|^2 = \int_{\mathbb{R}^d} \|u\|^2 \nu(du)$, then

$$d_{W_2}(\mu_X, \mu_Y) \leq \frac{1}{2} \left( \int_{\mathbb{R}^d} \|u\|^2 \nu(du) \right) \sqrt{U_Y - 1}. \quad (4.13)$$

**Proof of Theorem 4.5.** Let us start with the proof of (4.13). First, note that since $M_1(f_h) < +\infty$ and $M_2(f_h) < +\infty$, for $h \in H_0 \cap C_0^\infty(\mathbb{R}^d)$, $\nabla (f_h)$ belongs to $H_{\nu}(\mu_Y)$ with $f_h$ given by Proposition 3.5. Thus, since $EY = 0$, by Theorem 4.2,

$$d_{W_2}(\mu_X, \mu_Y) \leq \frac{1}{2} \left( \int_{\mathbb{R}^d} \|u\|^2 \nu(du) \right)^{1/2} S(\mu_Y \|\mu_X\|). \quad (4.14)$$

We continue by estimating $E \int_{\mathbb{R}^d} \|\tau_Y(Y + u) - \tau_Y(Y) - u\|^2 \nu(du)$. By the Pythagorean Theorem, Definition 4.1 and the fact that $E\|Y\|^2 = \int_{\mathbb{R}^d} \|u\|^2 \nu(du)$
On Stein’s method for multivariate self-decomposable laws with finite first moment

\[
E \int_{\mathbb{R}^d} \| \gamma_Y (Y + u) - \gamma_Y (Y) - u \|^2 \nu(du) = E \int_{\mathbb{R}^d} \| \gamma_Y (Y + u) - \gamma_Y (Y) \|^2 \nu(du) + \int_{\mathbb{R}^d} \| u \|^2 \nu(du) \\
- 2 E \int_{\mathbb{R}^d} \langle u; \gamma_Y (Y + u) - \gamma_Y (Y) \rangle \nu(du),
\]

where the definition of the Stein kernel has been used in the second equality with \( \gamma(v) \) finally, let us mention the work [51] where similar one-dimensional quantitative inequalities on the Stein discrepancy are a direct byproduct of the proof of the previous theorem.

(i) When \( E \| Y \|^2 = \int_{\mathbb{R}^d} \| u \|^2 \nu(du) \) and \( E Y = 0 \), note that \( U_Y \geq 1 \), since, in (4.3), one can take \( f(y) = y \), for all \( y \in \mathbb{R}^d \).

(ii) If \( Y \) is as in Theorem 4.5 with \( E \| Y \|^2 = \int_{\mathbb{R}^d} \| u \|^2 \nu(du) \), and if \( U_Y = 1 \), then, clearly from Theorem 4.5, \( Y =_d X \) since \( d_{W_2}(\mu_X, \mu_Y) = 0 \). Conversely, if \( Y =_d X \), with \( X \) as in Theorem 4.5, then, for all \( f = (f_1, \ldots, f_d) \), (4.1) asserts that

\[
E |f_j(Y) - E f_j(Y)|^2 \leq E \int_{\mathbb{R}^d} |f_j(Y + u) - f_j(Y)|^2 \nu(du),
\]

for all \( 1 \leq j \leq d \). Therefore, \( U_Y = 1 \).

(iii) The following inequality on the Stein discrepancy is a direct byproduct of the proof of the previous theorem

\[
S(\mu_Y | \mu_X) \leq \left( U_Y E \| Y \|^2 + \int_{\mathbb{R}^d} \| u \|^2 \nu(du) - 2 E \| Y \|^2 \right)^{1/2}.
\]

(iv) All the results presented above should be compared with the analogous Gaussian ones obtained in [16] (see [16, Theorem 2.4 and Corollary 2.5]).

(v) Finally, let us mention the work [51] where similar one-dimensional quantitative results have been obtained in the Gaussian and Poisson cases. More specifically, [51, Theorem 1] (respectively [51, Theorem 2]) provides upper bound on the total variation distance between a probability measure, for which an appropriate version of \( U(Y, \nu) \) defined by (4.2) is finite, and the Gaussian distribution (respectively the Poisson distribution).

The following convergence result is a straightforward consequence of Theorem 4.5.

**Corollary 4.7.** Let \( X \) be a centered non-degenerate self-decomposable random vector without Gaussian component, with law \( \mu_X \). Lévy measure \( \nu \), such that \( E \| X \|^2 < +\infty \) and let also the functions \( k_s \), given by (2.5) satisfy (3.2). Let \( (Y_n)_{n \geq 1} \) be a sequence of centered square-integrable non-degenerate random vectors with laws \( (\mu_n)_{n \geq 1} \), such that \( \nu * \mu_1 << \mu_n \), for all \( n \geq 1 \), and such that \( Y_n \) satisfies the Poincaré type inequality (4.3) with \( 1 \leq U_n < +\infty \), for all \( n \geq 1 \). If \( E \| Y_n \|^2 \to \int_{\mathbb{R}^d} \| u \|^2 \nu(du) \) and \( U_n \to 1 \), as \( n \) tends to \( +\infty \), then, \( (Y_n)_{n \geq 1} \) converges in distribution towards \( X \).
To end this section, we briefly discuss the condition $\nu * \mu_Y << \mu_Y$ appearing in Theorems 4.4 and 4.5. For this purpose, let $\nu$ be the Lévy measure of a non-degenerate infinitely divisible random vector, $X$, in $\mathbb{R}^d$ with law $\mu_X$. Now, let $\mathcal{P}(\nu)$ be the set of probability measures, $\mu$, on $\mathbb{R}^d$, such that $\nu * \mu << \mu$. First of all, thanks to [12, Lemma 4.1], the set $\mathcal{P}(\nu)$ is non-empty and contains the probability measure $\mu_X$. Moreover, it is clearly a convex set. Next, let us describe some further non-trivial examples of probability measures belonging to $\mathcal{P}(\nu)$. For this purpose, we say that two probability measures $\mu_1$ and $\mu_2$ on $\mathbb{R}^d$ are equivalent (denoted by $\mu_1 \sim \mu_2$) if for any Borel set $B$ of $\mathbb{R}^d$, $\mu_1(B) = 0$ if and only if $\mu_2(B) = 0$.

**Proposition 4.8.** Let $X$ be a non-degenerate infinitely divisible random vector in $\mathbb{R}^d$ with law $\mu_X$ and Lévy measure $\nu$ and $\mathcal{P}(\nu)$ be the set of probability measures, $\mu$, in $\mathbb{R}^d$ such that $\nu * \mu << \mu$. Let $Y$ be a non-degenerate random vector in $\mathbb{R}^d$ with law $\mu_Y$ such that $\mu_Y \sim \mu_X$. Then, $\mu_Y \in \mathcal{P}(\nu)$.

**Proof of Proposition 4.8.** Let $B$ be a Borel set of $\mathbb{R}^d$ such that $\mu_Y(B) = 0$. Then, $\mu_X(B) = 0$ since $\mu_Y \sim \mu_X$. But, $\mu_X \in \mathcal{P}(\nu)$, thus $\nu * \mu_X(B) = 0$. Finally, $\nu * \mu_Y << \nu * \mu_X$, since $\mu_Y \sim \mu_X$, and therefore, $\nu * \mu_Y(B) = 0$, which concludes the proof. □

As a further straightforward corollary, the following result holds true.

**Corollary 4.9.** Let $X$ be a non-degenerate infinitely divisible random vector in $\mathbb{R}^d$ without Gaussian component, with law $\mu_X$, Lévy measure $\nu_X$ and parameter $b_X \in \mathbb{R}^d$ and let $\mathcal{P}(\nu_X)$ be the set of probability measures, $\mu$, on $\mathbb{R}^d$ such that $\nu_X * \mu << \mu$. Let $Y$ be a non-degenerate infinitely divisible random vector in $\mathbb{R}^d$ without Gaussian component, with law $\mu_Y$, Lévy measure $\nu_Y$ and parameter $b_Y \in \mathbb{R}^d$. Assume that $\nu_X \sim \nu_Y$ and that

$$\int_{\mathbb{R}^d} \left( e^{\Phi(u)/2} - 1 \right)^2 \nu_X(du) < +\infty, \quad b_Y - b_X - \int \|u\| \leq 1 u(\nu_Y - \nu_X)(du) = 0,$$

where $\exp(\Phi(u)) = d\nu_Y / d\nu_X$, for all $u \in \mathbb{R}^d$. Then, $\mu_Y \in \mathcal{P}(\nu_X)$.

**Proof of Corollary 4.9.** This is a direct application of Proposition 4.8 together with [44, Theorem 33.1]. □

## Appendix

The aim of this section is to provide technical results (which are often multivariate versions of univariate ones proved in [1]) used throughout the previous sections.

**Lemma A.1.** Let $X$ be a non-degenerate self-decomposable random vector in $\mathbb{R}^d$, without Gaussian component, with law $\mu_X$, characteristic function $\varphi$ and such that $E\|X\| < \infty$. Assume further that, for any $0 < a < b < +\infty$ the functions $k_x$ given by (2.5) satisfy the following condition

$$\sup_{x \in S^{d-1}} \sup_{r \in (a,b)} k_x(r) < +\infty. \quad (A.1)$$

Let $X_t$, $t \geq 0$, be the random vectors each with characteristic functions, $\varphi_t$, given, for all $\xi \in \mathbb{R}^d$ by

$$\varphi_t(\xi) = \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)}. \quad (A.2)$$

Then,

(i)

$$\sup_{t > 0} E\|X_t\| < +\infty. \quad (A.3)$$
On Stein’s method for multivariate self-decomposable laws with finite first moment

and,

(ii) for all $\xi \in \mathbb{R}^d$ and all $t \in (0, 1),$

$$
\frac{1}{t} |\varphi_t(\xi)| - 1 - C(\|\xi\|\|EX\| + \|\xi\| + \|\xi\|^2),
$$

(A.4)

for some $C > 0$ independent of $\xi$ and $t.$

Proof of Lemma A.1. Let us start with the proof of (i). First note that, for all $t > 0,$

$$
X_t = (1 - e^{-t})EX + Y_t + Z_t,
$$

where $Y_t$ and $Z_t$ are independent, with, for all $\xi \in \mathbb{R}^d,$

$$
\mathbb{E} e^{i\langle \xi, Y_t \rangle} = \exp \left( \int_{u \in D} \left( e^{i\langle \xi, u \rangle} - 1 - i(\xi; u) \right) \nu_t(du) \right),
$$

$$
\mathbb{E} e^{i\langle \xi, Z_t \rangle} = \exp \left( \int_{u \in D^e} \left( e^{i\langle \xi, u \rangle} - 1 - i(\xi; u) \right) \nu_t(du) \right),
$$

with $\nu_t$ the Lévy measure of $X_t.$ Then, for all $t > 0,$

$$
\mathbb{E}\|X_t\| \leq (1 - e^{-t})\mathbb{E}\|X\| + \mathbb{E}\|Y_t\| + \mathbb{E}\|Z_t\|,
$$

and from [30, Lemma 1.1],

$$
\mathbb{E}\|X_t\| \leq (1 - e^{-t})\mathbb{E}\|X\| + \left( \int_{\|u\| \leq 1} \|u\|^2 \nu_t(du) \right)^{1/2} + 2 \int_{\|u\| \geq 1} \|u\| \nu_t(du).
$$

Now, thanks to the representation (3.5),

$$
\int_{\|u\| \leq 1} \|u\|^2 \nu_t(du) \leq \int_{\|u\| \leq 1} \|u\|^2 \nu(du), \quad \int_{\|u\| \geq 1} \|u\| \nu_t(du) \leq \int_{\|u\| \geq 1} \|u\| \nu(du).
$$

Thus,

$$
sup_{t \geq 0} \mathbb{E}\|X_t\| \leq \mathbb{E}\|X\| + \left( \int_{\|u\| \leq 1} \|u\|^2 \nu(du) \right)^{1/2} + 2 \int_{\|u\| \geq 1} \|u\| \nu(du) < +\infty.
$$

To prove (ii), first note that, for all $\xi \in \mathbb{R}^d$ with $\|\xi\| \neq 0$ and all $t > 0,$

$$
\mathbb{E} e^{i\langle \xi, X_t \rangle} - 1 = \int_0^{\|\xi\|} \left\langle \nabla(\varphi_t) \left( \frac{s \xi}{\|\xi\|} \right), \frac{\xi}{\|\xi\|} \right\rangle ds,
$$

and thus

$$
\left| \mathbb{E} e^{i\langle \xi, X_t \rangle} - 1 \right| \leq \|\xi\| \max_{s \in [0, \|\xi\|]} \left\| \nabla(\varphi_t) \left( \frac{s \xi}{\|\xi\|} \right) \right\|.
$$

Noting that, for all $\xi \in \mathbb{R}^d$ and all $1 \leq j \leq d,$

$$
\partial_j(\varphi_t)(\xi) = \left( iEX_j(1 - e^{-t}) + i \int_{\mathbb{R}^d} u_j \left( e^{i\langle u, \xi \rangle} - 1 \right) \nu_t(du) \right) \varphi_t(\xi),
$$

it follows that

$$
\left| \mathbb{E} e^{i\langle \xi, X_t \rangle} - 1 \right| \leq \|\xi\| (1 - e^{-t}) \sum_{j=1}^d \mathbb{E}|X_j| + \sqrt{d}\|\xi\|^2 \int_{\|u\| \leq 1} \|u\|^2 \nu_t(du).
$$
On Stein’s method for multivariate self-decomposable laws with finite first moment

\[ + 2|\xi|\sqrt{d} \int_{||u|| \geq 1} ||u|| \nu_1(du). \]

Next, the polar decomposition of \( \nu_1 \) allows to bound the terms \( \int_{||u|| \leq 1} ||u||^2 \nu_1(du) \) and \( \int_{||u|| \geq 1} ||u|| \nu_1(du) \). Let us start with \( \int_{||u|| \geq 1} ||u|| \nu_1(du) \). By (3.5),

\[
\int_{||u|| \geq 1} ||u|| \nu_1(du) = \int_{S^{d-1} \times (1, +\infty)} r k_x(r) - k_x(e^t r) \, dr \lambda(dx) \\
= \int_{S^{d-1}} \left( \int_1^t r k_x(r) \, dr + (1 - e^{-t}) \int_t^{+\infty} k_x(r) \, dr \right) \lambda(dx) \\
\leq (e^t - 1) \sup_{x \in S^{d-1}} |k_x(1^+) + (1 - e^{-t}) \int_{||u|| \geq 1} ||u|| \nu_1(du),
\]

which is finite in view of (A.1). For \( \int_{||u|| \leq 1} ||u||^2 \nu_1(du) \),

\[
\int_{||u|| \leq 1} ||u||^2 \nu_1(du) = \int_{S^{d-1} \times (0,1)} r k_x(r) - k_x(e^t r) \, dr \lambda(dx) \\
= \int_{S^{d-1}} \left( \int_0^1 r k_x(r) - k_x(e^t r) \, dr \right) \lambda(dx) \\
= \int_{S^{d-1}} \left( -e^{-2t} \int_1^0 r k_x(r) \, dr + (1 - e^{-2t}) \int_0^1 r k_x(r) \, dr \right) \lambda(dx) \\
\leq (1 - e^{-2t}) \int_{S^{d-1} \times (0,1)} r k_x(r) \, dr \lambda(dx).
\]

This concludes the proof of the lemma.

**Lemma A.2.** Let \( X \) and \( Y \) be two random vectors in \( \mathbb{R}^d \) with respective law \( \mu_X \) and \( \mu_Y \). Let \( r \geq 1 \). Then,

\[ d_{W_r}(\mu_X, \mu_Y) = \sup_{h \in \mathcal{H}_r \cap C_0^\infty(\mathbb{R}^d)} |Eh(X) - Eh(Y)|. \]  

(A.5)

**Proof of Lemma A.2.** Let \( r \geq 1 \). First, it is clear that

\[ d_{W_r}(\mu_X, \mu_Y) \geq \sup_{h \in \mathcal{H}_r \cap C_0^\infty(\mathbb{R}^d)} |Eh(X) - Eh(Y)|. \]

Now, let \( h \in \mathcal{H}_r \) and let \( (h_\varepsilon)_\varepsilon>0 \) be the regularization of \( h \) with the Gaussian kernel, namely, for all \( x \in \mathbb{R}^d \) and all \( \varepsilon > 0 \),

\[ h_\varepsilon(x) := \int_{\mathbb{R}^d} h(x - y) \exp \left( -\frac{||y||^2}{2\varepsilon^2} \right) \frac{dy}{(2\pi)^{d/2} \varepsilon^d}. \]

Note that \( h_\varepsilon \in C^\infty(\mathbb{R}^d) \), the space of infinitely differentiable functions on \( \mathbb{R}^d \), for all \( \varepsilon > 0 \). Moreover,

\[ ||h - h_\varepsilon||_\infty \leq \varepsilon, \quad M_\ell(h_\varepsilon) \leq 1, \quad 0 \leq \ell \leq r. \]

Next, let \( \Psi \) be a compactly supported infinitely differentiable function with values in \([0, 1]\) such that \( \text{supp}(\Psi) \subseteq D(0, 2) \), the closed Euclidean ball centered at the origin and of radius 2, and such that \( \Psi(x) = 1 \), for all \( x \in D \). Then, for any \( R \geq 1 \) and any \( \varepsilon > 0 \), set, for all \( x \in \mathbb{R}^d \),

\[ h_\varepsilon, R(x) := \Psi \left( \frac{x}{R} \right) h_\varepsilon(x). \]
On Stein’s method for multivariate self-decomposable laws with finite first moment

Then, for $X$ and $Y$ two random vectors on $\mathbb{R}^d$ with respective law $\mu_X$ and $\mu_Y$,

$$|\mathbb{E} h(X) - \mathbb{E} h(Y)| \leq |\mathbb{E} h_{\varepsilon,R}(X) - \mathbb{E} h_{\varepsilon,R}(Y)| + 2d\varepsilon + \int_{\mathbb{R}^d} \left( 1 - \Psi \left( \frac{x}{R} \right) \right) d\mu_X(x)$$

$$+ \int_{\mathbb{R}^d} \left( 1 - \Psi \left( \frac{x}{R} \right) \right) d\mu_Y(x),$$

$$\leq |\mathbb{E} h_{\varepsilon,R}(X) - \mathbb{E} h_{\varepsilon,R}(Y)| + 2d\varepsilon + P (\|X\| \geq R) + P (\|Y\| \geq R).$$

Now, for $R \geq 1$ such that $\max \{ P (\|X\| \geq R), P (\|Y\| \geq R) \} \leq \varepsilon,$

$$|\mathbb{E} h(X) - \mathbb{E} h(Y)| \leq |\mathbb{E} h_{\varepsilon,R}(X) - \mathbb{E} h_{\varepsilon,R}(Y)| + (2d + 2)\varepsilon.$$ 

To continue, one needs to estimate the quantities $M_\ell(h_{\varepsilon,R})$, for all $0 \leq \ell \leq r$. First, since $h \in \mathcal{H}_r$,

$$M_0(h_{\varepsilon,R}) := \sup_{x \in \mathbb{R}^d} |h_{\varepsilon,R}(x)| \leq 1.$$ 

But, for $v \in \mathbb{R}^d$ such that $\|v\| = 1$ and $x \in \mathbb{R}^d$,

$$D(h_{\varepsilon,R})(v)(x) = \sum_{i=1}^d v_i \partial_i (h_{\varepsilon,R})(x)$$

$$= \frac{1}{R} \sum_{i=1}^d v_i h_{\varepsilon}(x) \partial_i (\Psi) \left( \frac{x}{R} \right) + \Psi \left( \frac{x}{R} \right) \sum_{i=1}^d v_i \partial_i (h_{\varepsilon})(x)$$

$$= \frac{h_{\varepsilon}(x)}{R} \langle \nabla (\Psi) \left( \frac{x}{R} \right); v \rangle + \Psi \left( \frac{x}{R} \right) \langle \nabla h_{\varepsilon}(x); v \rangle.$$ 

Thus, for all $R \geq 1$ and all $\varepsilon > 0$

$$M_1(h_{\varepsilon,R}) \leq \frac{1}{R} \sup_{x \in \mathbb{R}^d} \|\nabla (\Psi)(x)\| + 1.$$ 

With a similar reasoning, it follows that $M_\ell(h_{\varepsilon,R}) \leq C_{\ell,\Psi} \left( \sum_{k=1}^{r} 1/R^k \right) + 1$, for all $1 \leq \ell \leq r$, and for some $C_{\ell,\Psi} > 0$ only depending on $\ell$ and $\Psi$. Hence, the function $\tilde{h}_{\varepsilon,R}$ defined, for all $x \in \mathbb{R}^d$, by

$$\tilde{h}_{\varepsilon,R}(x) := \frac{h_{\varepsilon,R}(x)}{\max_{1 \leq \ell \leq r} \left( C_{\ell,\Psi} \left( \sum_{k=1}^{r} 1/R^k \right) + 1 \right)}$$

belongs to $\mathcal{H}_r \cap C_\infty^\alpha(\mathbb{R}^d)$. Finally,

$$|\mathbb{E} h(X) - \mathbb{E} h(Y)| \leq \left( \max_{1 \leq \ell \leq r} \left( C_{\ell,\Psi} \left( \sum_{k=1}^{r} 1/R^k \right) + 1 \right) \right) \left| \mathbb{E} \tilde{h}_{\varepsilon,R}(X) - \mathbb{E} \tilde{h}_{\varepsilon,R}(Y) \right| + (2d + 2)\varepsilon$$

$$\leq \left( \max_{1 \leq \ell \leq r} \left( C_{\ell,\Psi} \left( \sum_{k=1}^{r} 1/R^k \right) + 1 \right) \right) \sup_{h \in \mathcal{H}_r \cap C_\infty^\alpha(\mathbb{R}^d)} |\mathbb{E} h(X) - \mathbb{E} h(Y)| + (2d + 2)\varepsilon.$$ 

Letting first $R$ tend to $+\infty$ and then $\varepsilon$ tend to $0^+$ concludes the proof of the lemma. □

The objective of Theorem A.4 below is to prove that the $d_{W_1}$ distance, between the law of $X$ and the law of $X_t$, decreases exponentially fast as $t$ tends to $+\infty$. For this purpose, for any $r \geq 1$ and any random vectors $X$ and $Y$, let

$$d_{W_1}(X,Y) = \sup_{h \in \mathcal{H}_r} |\mathbb{E} h(X) - \mathbb{E} h(Y)|,$$

Page 26/33
On Stein’s method for multivariate self-decomposable laws with finite first moment

where \( \tilde{H}_r \) is the set of functions which are \( r \)-times continuously differentiable on \( \mathbb{R}^d \) such that \( \|D^\alpha (f)\|_\infty \leq 1 \), for all \( \alpha \in \mathbb{N}^d \) with \( 0 \leq \|\alpha\| \leq r \). Since, for any \( r \geq 1 \), \( H_r \subseteq \tilde{H}_r \),

\[
dw_r(X, Y) \leq dw_{\tilde{r}}(X, Y).
\] (A.7)

The next lemma shows that in (A.6), it is enough to take the supremum over smooth compactly supported functions in \( H_r, r \geq 1 \).

**Lemma A.3.** Let \( X \) and \( Y \) be two random vectors in \( \mathbb{R}^d \) with respective law \( \mu_X \) and \( \mu_Y \). Let \( r \geq 1 \). Then,

\[
dw_r(\mu_X, \mu_Y) = \sup_{h \in \tilde{H}_r \cap C_c^\infty (\mathbb{R}^d)} |Eh(X) - Eh(Y)|. \] (A.8)

**Proof of Lemma A.3.** By definition,

\[
dw_r(\mu_X, \mu_Y) \geq \sup_{h \in \tilde{H}_r \cap C_c^\infty (\mathbb{R}^d)} |Eh(X) - Eh(Y)|.
\]

Let \( h \in \tilde{H}_r \) and let \( (h_\varepsilon)_{\varepsilon > 0} \) be a regularization by convolution of \( h \), such that \( h_\varepsilon \in C_c^\infty (\mathbb{R}^d) \) and

\[
\|h - h_\varepsilon\|_∞ \leq \varepsilon, \quad \|D^\alpha (h_\varepsilon)\|_∞ \leq 1, \quad \alpha \in \mathbb{N}^d, \quad 0 \leq \|\alpha\| \leq r, \quad r \geq 1.
\]

Let \( \psi \) be a compactly supported, even, infinitely differentiable function on \( \mathbb{R} \) with values in \([0, 1]\) such that \( \psi(x) = 1 \), for \( x \in [-1, 1] \). Then, for all \( M \geq 1 \), \( \varepsilon > 0 \) and \( x \in \mathbb{R}^d \) set

\[
\Psi_M(x) = \prod_{i=1}^d \psi(\frac{x_i}{M})
\]

and set also,

\[
h_{M, \varepsilon}(x) = \Psi_M(x) h_\varepsilon(x).
\]

Clearly, by construction, \( h_{M, \varepsilon} \in C_c^\infty (\mathbb{R}^d) \). Then, for all \( M \geq 1 \) and \( \varepsilon > 0 \),

\[
|Eh(X) - Eh(Y)| \leq |Eh_{M, \varepsilon}(X) - Eh_{M, \varepsilon}(Y)| + 2d\varepsilon + \int_{\mathbb{R}^d} |1 - \Psi_M(x)| \, d\mu_X(x)
\]

\[
+ \int_{\mathbb{R}^d} |1 - \Psi_M(y)| \, d\mu_Y(y).
\]

Choosing \( M \geq 1 \) large enough,

\[
|Eh(X) - Eh(Y)| \leq |Eh_{M, \varepsilon}(X) - Eh_{M, \varepsilon}(Y)| + (2d + 2)\varepsilon.
\]

Next, by the very definition of \( h_{M, \varepsilon} \)

\[
\|h_{M, \varepsilon}\|_∞ \leq 1,
\]

and, moreover, by Leibniz formula, for all \( \alpha \in \mathbb{N}^d \) with \( 1 \leq \|\alpha\| \leq r \) and \( x \in \mathbb{R}^d \),

\[
|D^\alpha (h_{M, \varepsilon})(x)| \leq \sum_{\beta \leq \alpha} \binom{\alpha}{\beta} |D^\beta (\Psi_M)(x)| |D^{\alpha - \beta} (h_\varepsilon)(x)|
\]

\[
\leq |D^\alpha (h_\varepsilon)(x)| + \sum_{\beta \leq \alpha, \beta \neq 0} \binom{\alpha}{\beta} |D^\beta (\Psi_M)(x)| |D^{\alpha - \beta} (h_\varepsilon)(x)|
\]

\[
\leq 1 + \sum_{\beta \leq \alpha, \beta \neq 0} \binom{\alpha}{\beta} |D^\beta (\Psi_M)(x)|.
\]

Now, for all \( \beta \leq \alpha \), \( \beta \neq 0 \) and \( x \in \mathbb{R}^d \),

\[
|D^\beta (\Psi_M)(x)| \leq \frac{1}{M^{\beta_1}} \prod_{1 \leq j \leq d} \sup_{x \in \mathbb{R}} |\psi(\beta_j)(x)|,
\]

\[
\frac{1}{M^{\beta_1}} \prod_{1 \leq j \leq d} \sup_{x \in \mathbb{R}} |\psi(\beta_j)(x)|.
\]
On Stein’s method for multivariate self-decomposable laws with finite first moment

Thus,

\[ |D^\alpha (h_{M,\varepsilon})(x)| \leq 1 + C_{d,\alpha} \sum_{\beta \leq \alpha, \beta \neq 0} \frac{1}{M^{1/\beta_1}} \]

for some \( C_{d,\alpha} > 0 \) only depending on \( d, \alpha \) and \( \psi \). This implies that

\[ |E h(X) - E h(Y)| \leq \left( 1 + C_{d,r} \sum_{1 \leq |\alpha| \leq r} \sum_{\beta \leq \alpha, \beta \neq 0} \frac{1}{M^{1/\beta_1}} \right) \sup_{c \in \mathbb{C}(R^d)} |E h(X) - E h(Y)| \\
+ (2d + 2)\varepsilon, \]

for some \( C_{d,r} > 0 \) only depending on \( d, r \) and \( \psi \). The conclusion follows by, first taking \( M \to +\infty \), and then \( \varepsilon \to 0^+ \).

\( \Box \)

**Theorem A.4.** Let \( X \) be a non-degenerate self-decomposable random vector in \( R^d \), without Gaussian component, with law \( \mu_X \), characteristic function \( \varphi \) and such that \( E \|X\| < \infty \). Assume further that, for any \( 0 < a < b < +\infty \) the functions \( k_x \) given by (2.5) satisfy the following condition

\[ \sup_{x \in S_{d-1}} \sup_{r \in (a,b)} k_x(r) < +\infty. \quad (A.9) \]

Let \( X_t, t > 0 \) be random vectors each with law \( \mu_{X_t} \), with characteristic function \( \varphi_t \), given, for all \( \xi \in R^d \) by

\[ \varphi_t(\xi) = \frac{\varphi(\xi)}{\varphi(e^{-t}\xi)}. \quad (A.10) \]

Then, for \( t > 0 \),

\[ d_{W_1}(\mu_{X_t}, \mu_X) \leq C_d e^{-\frac{t}{2(\alpha + 1)}}, \quad (A.11) \]

for some \( C_d > 0 \) independent of \( t \).

**Proof of Theorem A.4.** Step 1: Let \( r \geq 2 \) and let \( h \in \tilde{H}_{r-1} \). Let \( (h_{\varepsilon})_{\varepsilon > 0} \) be a regularization by convolution of \( h \) such that

\[ \|h - h_{\varepsilon}\|_\infty \leq \varepsilon, \quad \|D^\alpha (h_{\varepsilon})\|_\infty \leq 1, \quad 0 \leq |\alpha| \leq r - 1. \]

For \( \alpha \in \mathbb{N}^d \) such that \( |\alpha| = r \), let us estimate \( \|D^\alpha (h_{\varepsilon})\|_\infty \). By definition, for all \( x \in R^d \),

\[ h_{\varepsilon}(x) = \int_{R^d} h(y) \exp \left( -\frac{\|x - y\|^2}{2\varepsilon^2} \right) \frac{dy}{(2\pi)^{d/2} \varepsilon^d}. \]

Now, by Rodrigues formula, for all \( j \in 1, ..., d \),

\[ \partial_{x_j}^{\alpha_j} \left( \exp \left( -\frac{x_j^2}{2} \right) \right) = (-1)^{\alpha_j} H_{\alpha_j}(x_j) \exp \left( -\frac{x_j^2}{2} \right). \]

where \( H_{\alpha_j} \) is the Hermite polynomial of degree \( \alpha_j \). Thus, for all \( \alpha \in \mathbb{N}^d \) and \( x \in R^d \),

\[ D^\alpha \left( \exp \left( -\frac{\|x\|^2}{2} \right) \right) = (-1)^{\alpha} H_{\alpha}(x) \exp \left( -\frac{\|x\|^2}{2} \right). \]
On Stein’s method for multivariate self-decomposable laws with finite first moment

where \( H_\alpha(x) = \prod_{j=1}^d H_\alpha(x_j) \). Hence, for all \( \alpha \in \mathbb{N}^d \) such that \( |\alpha| = r \), for all \( x \in \mathbb{R}^d \) and for some \( \beta \in \mathbb{N}^d \) such that \( |\beta| = r - 1 \) and \( \alpha - \beta \geq 0 \)

\[
D^\alpha(h_{\varepsilon})(x) = \int_{\mathbb{R}^d} D^\beta(h(y)) D^{\alpha - \beta} \left( \exp \left( -\frac{||x-y||^2}{2\varepsilon^2} \right) \right) \frac{dy}{(2\pi)^{\frac{d}{2}}}.
\]

\[
D^\alpha(h_{\varepsilon})(x) = \frac{(-1)^r}{\varepsilon^d} \int_{\mathbb{R}^d} D^\beta(h(y)) H_{\alpha - \beta}(x - y) \exp \left( -\frac{||x-y||^2}{2\varepsilon^2} \right) \frac{dy}{(2\pi)^{\frac{d}{2}}}.
\]

Then,

\[
\|D^\alpha(h_{\varepsilon})\|_\infty \leq \frac{1}{\varepsilon} \int_{\mathbb{R}^d} |H_{\alpha - \beta}(y)| \exp \left( -\frac{||y||^2}{2} \right) \frac{dy}{(2\pi)^{\frac{d}{2}}} \leq C_{\alpha} \varepsilon^{-1} \leq C_r \varepsilon^{-1},
\]

for some \( C_{\alpha} > 0, C_r > 0 \) depending only on \( \alpha \), on \( d \) and on \( r \). Let \( Z \) and \( Y \) be two random vectors with respective law \( \mu_Z \) and \( \mu_Y \) such that \( d_{W_r}(Z, Y) < 1 \). Then,

\[
|E \mu_Z - E \mu_Y| \leq 2d \varepsilon + |E \mu_Z - E \mu_Y|.
\]

Choosing \( \varepsilon \in (0, C_r) \),

\[
|E \mu_Z - E \mu_Y| \leq 2d \varepsilon + \frac{C_r}{\varepsilon} d_{W_r}(Z, Y)
\]

\[
\leq \max(2d, C_r) \left( \varepsilon + \varepsilon^{-1} d_{W_r}(Z, Y) \right).
\]

Taking \( \varepsilon \leq C_r / (1 + C_r) \sqrt{d_{W_r}(Z, Y)} \) yields,

\[
d_{W_{r-1}}(Z, Y) \leq \tilde{C}_r \sqrt{d_{W_r}(Z, Y)},
\]

for some \( \tilde{C}_r > 0 \) only depending on \( r \) and on \( d \). Now, let \( Z \) and \( Y \) be two random vectors such that \( d_{W_r}(Z, Y) < 1 \). Then, thanks to (2.15), \( d_{W_m}(Z, Y) < 1 \), for all \( 2 \leq m \leq r \). By induction, we get

\[
d_{W_{r-1}}(Z, Y) \leq \frac{C_r}{\sqrt{d_{W_r}(Z, Y)}} \frac{m-1}{m}, \quad (A.12)
\]

for some \( \overline{C}_r > 0 \) only depending on \( r \) and on \( d \).

**Step 2:** Let \( g \) be an infinitely differentiable function with compact support contained in the closed Euclidean ball centered at the origin of radius \( R + 1 \), for some \( R > 0 \). Then by Fourier inversion and Fubini theorem, for all \( t > 0 \),

\[
|E g(X) - E g(X_t)| \leq e^{-tE\|X\|} \left( \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |F(g)(\xi)| \|\xi\| d\xi \right)
\]

\[
\leq e^{-tE\|X\|} \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |F(g)(\xi)| \left( \frac{1 + \|\xi\|}{1 + \|\xi\|} \right)^{d+2} \|\xi\| d\xi
\]

\[
\leq e^{-tE\|X\|} \sup_{\xi \in \mathbb{R}^d} \left( |F(g)(\xi)| \left( 1 + \|\xi\|^{d+2} \right) \right) \left( \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} \frac{\|\xi\| d\xi}{(1 + \|\xi\|)^{d+2}} \right).
\]

Moreover, for all \( p \geq 2 \)

\[
\sup_{\xi \in \mathbb{R}^d} \left( |F(g)(\xi)| \left( 1 + \|\xi\|^p \right) \right) \leq C_d (R + 1)^d \left( \|g\|_\infty + \max_{1 \leq j \leq d} \|\partial_{\xi_j}^p g\|_\infty \right).
\]

EJP 24 (2019), paper 29. http://www.imstat.org/ejp/
On Stein’s method for multivariate self-decomposable laws with finite first moment

for some $C_d > 0$ depending on the dimension $d$ only. Thus, for all $t > 0$

$$|Eg(X) - Eg(X_t)| \leq \tilde{C}_d e^{-t} E\|X\|(R + 1)^d \left(\|g\|_\infty + \max_{1 \leq j \leq d} \|\partial^{d+2}_j (g)\|_\infty\right). \quad (A.13)$$

**Step 3:** Let $h \in C^\infty_c (\mathbb{R}^d) \cap \mathcal{F}_{d+2}$. Let $\Psi_R$ be a compactly supported infinitely differentiable function on $\mathbb{R}^d$ whose support is contained in the closed Euclidean ball centered at the origin of radius $R + 1$, with values in $[0,1]$ and such that $\Psi_R(x) = 1$, for all $x$ such that $\|x\| \leq R$. Then, for all $t > 0$

$$|Eh(X) - Eh(X_t)| \leq |Eh(X)\psi_R(X) - Eh(X_t)\Psi_R(X_t)| + |Eh(X)(1 - \Psi_R(X))| + |Eh(X_t)(1 - \Psi_R(X_t))|.$$

Next, note that

$$|Eh(X_t)(1 - \Psi_R(X_t))| \leq \int_{\mathbb{R}^d} (1 - \Psi_R(x)) d\mu_t(x) \leq P(\|X_t\| \geq R) \leq \frac{E\|X_t\|}{R} \leq \frac{1}{R} \sup_{t > 0} E\|X_t\|,$$

using Lemma A.1. A similar bound holds true for $|Eh(X)(1 - \Psi_R(X))|$. Moreover, from (A.13),

$$|Eh(X) - Eh(X_t)| \leq \frac{C_d}{R} + \tilde{C}_d e^{-t} E\|X\|(R + 1)^d \left(\|h\Psi_R\|_\infty + \max_{1 \leq j \leq d} \|\partial^{d+2}_j (h\Psi_R)\|_\infty\right),$$

for some constant $C_d$ depending on $d$. Now,

$$\|h\Psi_R\|_\infty \leq 1,$$

and, by taking for $\Psi_R$ an appropriate tensorization of one dimensional bump functions $\psi_R$,

$$\max_{1 \leq j \leq d} \|\partial^{d+2}_j (h\Psi_R)\|_\infty \leq \tilde{D},$$

for some $\tilde{D} > 0$ independent of $R$ and $h$. Hence,

$$|Eh(X) - Eh(X_t)| \leq C_d \left(\frac{1}{R} + (R + 1)^d e^{-t} E\|X\|\right).$$

Choosing $R = e^{t/(d+1)}$, for all $t > 0$, it follows that

$$d_{W_{d+2}}(X,X_t) \leq \tilde{C}_d e^{-\frac{t}{d+1}},$$

for some $\tilde{C}_d > 0$, and from (A.12) with $r = d + 2$,

$$d_{\tilde{W}_1}(X,X_t) \leq \overline{C}_d \left(d_{W_{d+2}}(X,X_t)\right)^{\frac{1}{d+1}} \leq C_d e^{-\frac{t}{d+1}(d+1)}.$$

The inequality (A.7) concludes the proof of the theorem.

Math. J. 30(3):490–493, 1989. MR-1010851

Acknowledgments. We are grateful to an anonymous referee and to an associate editor
for insightful remarks which led to improvements in the presentation of this manuscript.
Advantages of publishing in EJP-ECP

- Very high standards
- Free for authors, free for readers
- Quick publication (no backlog)
- Secure publication (LOCKSS\(^1\))
- Easy interface (EJMS\(^2\))

Economical model of EJP-ECP

- Non profit, sponsored by IMS\(^3\), BS\(^4\), ProjectEuclid\(^5\)
- Purely electronic

Help keep the journal free and vigorous

- Donate to the IMS open access fund\(^6\) (click here to donate!)
- Submit your best articles to EJP-ECP
- Choose EJP-ECP over for-profit journals
