The quasi-bound states of charged massive scalar fields in the near-extremal charged Reissner-Nordström black-hole spacetime are studied analytically. These discrete resonant modes of the composed black-hole-field system are characterized by the physically motivated boundary condition of ingoing waves at the black-hole horizon and exponentially decaying (bounded) radial eigenfunctions at spatial infinity. Solving the Klein-Gordon wave equation for the linearized scalar fields in the black-hole spacetime, we derive a remarkably compact analytical formula for the complex frequency spectrum which characterizes the quasi-bound state resonances of the composed Reissner-Nordström-black-hole-charged-massive-scalar-field system.

I. INTRODUCTION

The powerful no-hair theorems of Bekenstein and Mayo [1] (see also [2–5]) have revealed the fact that, in asymptotically flat spacetimes, spherically symmetric charged black holes cannot support external static matter configurations made of charged massive scalar fields. It should be emphasized, however, that these mathematically elegant no-hair theorems [1] do not address the following physically interesting question: how long does it take for a newly born charged black hole to shed (that is, to swallow or to radiate to infinity) the external charged fields?

Interestingly, recent numerical investigations [6] of the Klein-Gordon wave equation for charged massive scalar fields in the spherically symmetric Reissner-Nordström black-hole spacetime have demonstrated explicitly that exponentially decaying quasi-bound state charged matter configurations, which are characterized by extremely long lifetimes [7], can be supported in the external spacetime region of the central charged black hole. These external quasi-bound field configurations are characterized by the physically motivated boundary condition of ingoing waves at the outer black-hole horizon and exponentially decaying (bounded) radial eigenfunctions at spatial infinity [8–12].

The main goal of the present paper is to explore the physical properties of these quasi-bound state charged matter configurations in the Reissner-Nordström-black-hole spacetime. To this end, we shall analyze the Klein-Gordon wave equation for the charged massive scalar fields in the charged black-hole spacetime. Interestingly, as we shall explicitly show below, in the extremal $Q/M \to 1$ limit [13, 14] of the central charged black hole, one can derive a remarkably compact analytical formula for the discrete frequency spectrum which characterizes the quasi-bound state resonances of the composed Reissner-Nordström-black-hole-charged-massive-scalar-field configurations.

II. DESCRIPTION OF THE SYSTEM

We consider a scalar field $\Psi$ of mass $\mu$ and charge coupling constant $q$ [15] which is linearly coupled to a Reissner-Nordström black hole of mass $M$ and electric charged $Q$ [16]. The charged black-hole spacetime is described by the spherically symmetric metric [17]

$$ds^2 = -f(r)dt^2 + \frac{1}{f(r)}dr^2 + r^2(d\theta^2 + \sin^2 \theta d\phi^2) ,$$

where

$$f(r) = 1 - \frac{2M}{r} + \frac{Q^2}{r^2} .$$

The horizon radii which characterize the charged Reissner-Nordström black-hole spacetime,

$$r_\pm = M \pm (M^2 - Q^2)^{1/2} ,$$

are determined by the zeros of the dimensionless metric function $f(r)$ [17].

The dynamics of the linearized charged massive scalar fields in the curved black-hole spacetime is governed by the familiar Klein-Gordon wave equation [8–12, 18, 20]

$$[(\nabla^\nu - iqA^\nu)(\nabla_\nu - iqA_\nu) - \mu^2] \Psi = 0 ,$$

where $\nabla^\nu$ and $\nabla_\nu$ are the covariant derivatives in the spacetime metric $g_{\mu\nu}$. The boundary conditions at the black-hole horizon $r = r_+$ and at spatial infinity $r \to \infty$ ensure that the solutions are regular at these points and that the wavefunction is exponentially localized in the exterior region.

By solving the Klein-Gordon equation under these boundary conditions, one obtains a remarkably compact analytical formula for the complex frequency spectrum which characterizes the quasi-bound state resonances of the composed Reissner-Nordström-black-hole-charged-massive-scalar-field system.
where $A_\nu = -\delta_\nu^0 Q/r$ is the electromagnetic potential of the Reissner-Nordström black hole. Substituting into (3) the metric functions (1) and using the scalar field expansion [21]

$$\Psi(t,r,\theta,\phi) = \int \sum_{lm} e^{im\phi} S_{lm}(\theta) R_{lm}(r;\omega) e^{-i\omega t} d\omega,$$

one finds the characteristic radial differential equation [18–20]

$$f(r) \frac{d}{dr} \left[ r^2 f(r) \frac{dR}{dr} \right] + UR = 0 \quad (6)$$

for the radial scalar eigenfunction $R(r)$, where [22]

$$U = (\omega r - qQ)^2 - f(r) \left[ \mu^2 r^2 + l(l + 1) \right]. \quad (7)$$

We shall be interested in resonant modes of the charged massive scalar fields in the charged black-hole spacetime which are characterized by the physically motivated boundary condition [6, 23]:

$$R(r \to r_+) \sim e^{-i(\omega - \omega_c) y} \quad (8)$$

of purely ingoing waves (as measured by a comoving observer) at the outer horizon of the black hole, where

$$\omega_c = \frac{qQ}{r_+} \quad (9)$$

is the critical (marginal) frequency for the superradiant scattering phenomenon of charged bosonic fields in the charged Reissner-Nordström black-hole spacetime [24], and the radial coordinate $y$ is defined by the relation $dy/dr = 1/f(r)$ [22]. In addition, the quasi-bound state resonances of the linearized charged massive scalar fields that we shall analyze in the present paper are characterized by the asymptotic boundary condition [6, 23]

$$R(r \to \infty) \sim \frac{1}{r} e^{-\sqrt{\mu^2 - \omega^2} r} \quad (10)$$

of exponentially decaying radial eigenfunctions in the bounded regime

$$\omega^2 < \mu^2 \quad (11)$$

of small resonant frequencies.

The characteristic quasi-bound state resonances \{\(\omega(\mu, q, l, M, Q; n)\}\} [20] of the charged massive scalar fields in the charged Reissner-Nordström black-hole spacetime are determined by the set of equations (6), (8), and (10). Interestingly, as we shall explicitly show in the next section, the complex resonant spectrum which characterizes the quasi-bound state resonances of the composed Reissner-Nordström-black-hole-charged-massive-scalar-field system can be determined analytically in the near-extremal \((r_+ - r_-)/r_+ \ll 1\) regime.

### III. THE QUASI-BOUND STATE RESONANCES OF THE CHARGED MASSIVE SCALAR FIELDS IN THE CHARGED REISSNER-NORDSTRÖM BLACK-HOLE SPACETIME

In the present section we shall study analytically the set of equations (6), (8), and (10) which determine the quasi-bound state resonances of the charged massive scalar fields. In particular, below we shall derive a remarkably compact analytical formula for the complex resonant spectrum which characterizes the quasi-bound state massive scalar configurations in the charged Reissner-Nordström black-hole spacetime.

It proves useful to define the dimensionless physical parameters [19, 27]

$$x \equiv \frac{r - r_+}{r_+}; \quad \tau \equiv \frac{r_+ - r_-}{r_+}; \quad k \equiv 2\omega r_+ - qQ; \quad \omega \equiv \frac{\omega - \omega_c}{2\pi T_{BH}} \quad (12)$$

which characterize the composed Reissner-Nordström-black-hole-charged-massive-scalar-field system, where

$$T_{BH} = \frac{r_+ - r_-}{4\pi r_+^2} \quad (13)$$
is the Bekenstein-Hawking temperature of the charged black hole. In addition, we shall use the dimensionless black-hole-field parameter
\[ \beta^2 \equiv (l + 1/2)^2 + (\mu r_+)^2 - k^2 . \] (14)
Below we shall assume \( 0 < \beta \in \mathbb{R}^+ \).

Using the dimensionless parameters \( \{1, 2\} \), one can express the radial differential equation \( (\ref{15}) \) in the from \( \{3, 4\} \)
\[ x(x + \tau) \frac{d^2 R}{dx^2} + (2x + \tau) \frac{dR}{dx} + UR = 0 , \] (15)
where the effective radial potential is given by
\[ U = U(x; \mu, q, \omega, l, M, Q) = \frac{(\omega r_+ x^2 + k x + x\tau/2)^2}{x(x + \tau)} - l(l + 1) - (\mu r_+ + x)^2 . \] (16)
As shown in \( \{3\} \), for near-extremal black holes in the \( \tau \ll 1 \) regime, the characteristic differential equation \( (\ref{16}) \) is amenable to an analytical treatment in the two asymptotic regions \( x \ll 1 \) and \( x \gg \tau \times \max(1, \omega) \) \( \{23\} \). Interestingly, and most importantly for our analysis, by performing a standard matching procedure of the two analytical solutions \( \{9\} \), one may determine the complex spectrum \( \{\omega_1(\mu, q, l, M, Q; n)\} \) of resonant frequencies which characterize the quasi-bound state configurations of the charged massive scalar fields in the charged Reissner-Nordström black-hole spacetime.

We shall first analyze the radial equation \( (\ref{15}) \) in the near-horizon region
\[ x \ll 1 . \] (17)
In this spatial region one may approximate the effective radial potential \( (\ref{16}) \) by \( U \rightarrow U_{\text{near}} \equiv (k x + x\tau/2)/[x(x + \tau)] - l(l + 1) - (\mu r_+)^2 . \) One can express the physically acceptable \( \{31\} \) near-horizon solution of the radial differential equation \( (\ref{15}) \) in the form \( \{9, 29, 32, 33\} \)
\[ R(x) = x^{-i\frac{\omega}{2}}(\frac{x}{\tau} + 1)^{i\frac{\omega}{2} - ik} \times \frac{\Gamma(1 - i\omega)\Gamma(-2\beta)}{\Gamma(1/2 - \beta - ik)\Gamma(1/2 - \beta + ik - i\omega)} (\frac{x}{\tau})^{-1/2 - \beta + ik} \times 2F1(\frac{1}{2} + \beta - ik, \frac{1}{2} + \beta - ik; 1 - i\omega; -x/\tau) , \] (18)
where \( 2F1(a, b; c; z) \) is the familiar hypergeometric function.

Using Eq. 15.3.7 of \( \{33\} \) one may express \( (\ref{19}) \) in the form
\[ R(x) = x^{4\frac{\omega}{2}}(\frac{x}{\tau} + 1)^{4\frac{\omega}{2} - 4ik} \times \frac{\Gamma(1 - i\omega)\Gamma(-2\beta)}{\Gamma(1/2 - \beta - ik)\Gamma(1/2 - \beta + ik - i\omega)} (\frac{x}{\tau})^{-1/2 - \beta + 4ik} \times 2F1(\frac{1}{2} + \beta - ik, \frac{1}{2} + \beta - ik + i\omega; 1 + 2\beta; -x/\tau) + (\beta \rightarrow -\beta) , \] (19)
where the notation \( \beta \rightarrow -\beta \) means “replace \( \beta \) by \( -\beta \) in the preceding term”. Substituting into \( (\ref{19}) \) the asymptotic expression (see Eq. 15.1.1 of \( \{33\} \))
\[ 2F1(a, b; c; z) \rightarrow 1 \text{ for } \frac{ab}{c} \cdot z \rightarrow 0 , \] (20)
one obtains \( \{9\} \)
\[ R(x) = \frac{\Gamma(1 - i\omega)\Gamma(-2\beta)\tau^{1/2 + \beta - i\omega/2}}{\Gamma(1/2 - \beta - ik)\Gamma(1/2 - \beta + ik - i\omega)} x^{\frac{\omega}{2} - \beta} + (\beta \rightarrow -\beta) \] (21)
in the intermediate spatial region
\[ \tau \times \max(1, \omega) \ll x \ll 1 . \] (22)

We shall next analyze the radial scalar equation \( (\ref{15}) \) in the far-region
\[ x \gg \tau \times \max(1, \omega) . \] (23)
In this spatial region one may approximate \( (\ref{15}) \) by \( \{9\} \)
\[ x^2 \frac{d^2 R}{dx^2} + 2x \frac{dR}{dx} + U_{\text{far}} R = 0 , \] (24)
where the effective far-region potential is given by $U \to U_{\text{far}} = (\omega r_+ x + k)^2 - l(l + 1) - [\mu r_+(1 + x)]^2$. Defining the dimensionless variables

$$
\epsilon \equiv \sqrt{\mu^2 - \omega^2 r_+} \quad ; \quad \kappa \equiv \frac{\omega kr_+ - (\mu r_+)^2}{\epsilon},
$$

one can express the far-region solution of radial differential equation (24) in the form \cite{9, 29, 32, 33}

$$
R(x) = N_1 \times (2\epsilon)^\frac{1}{2} x^{-\frac{1}{2} - \beta} e^{-\epsilon x} F_1 \left(\frac{1}{2} - \beta - \kappa, 1 - 2\beta, 2\epsilon x\right) + N_2 \times (\beta \to -\beta),
$$

where $F_1(a, b, z)$ is the familiar confluent hypergeometric function and $\{N_1, N_2\}$ are normalization constants.

Substituting into (26) the asymptotic expression (see Eq. 13.1.2 of \cite{33})

$$
1 F_1(a, b, z) \to 1 \quad \text{for} \quad \frac{a}{b}, z \to 0,
$$

one obtains \cite{9}

$$
R(x) = N_1 \times (2\epsilon)^\frac{1}{2} x^{-\frac{1}{2} - \beta} + N_2 \times (\beta \to -\beta)
$$

in the intermediate spatial region

$$
\tau \times \text{max}(1, \omega) \ll x \ll 1.
$$

Matching the analytically derived radial solutions (21) and (28), which are both valid in the overlap region $\tau \times \text{max}(1, \omega) \ll x \ll 1$, one finds the normalization constants \cite{9, 34}

$$
N_1(\beta) = \frac{\Gamma(1 - i\omega)}{\Gamma(\frac{1}{2} - \beta - ik) \Gamma(\frac{1}{2} - \beta + i\omega)} \tau^{-\frac{1}{2} + \beta + i\omega} \quad \text{and} \quad N_2(\beta) = N_1(-\beta)
$$

of the radial solution (26). In addition, using Eq. 13.5.1 of \cite{33}, one finds the asymptotic spatial behavior

$$
R(x \to \infty) \to \left[ N_1 \times (2\epsilon)^\kappa \frac{\Gamma(1 - 2\beta)}{\Gamma(\frac{1}{2} - \beta + \kappa)} x^{-1 + \kappa} (-1)^{-\frac{1}{2} + \beta + \kappa} + N_2 \times (\beta \to -\beta) \right] e^{-\epsilon x}
$$

$$
+ \left[ N_1 \times (2\epsilon)^{-\kappa} \frac{\Gamma(1 - 2\beta)}{\Gamma(\frac{1}{2} - \beta - \kappa)} x^{-1 - \kappa} + N_2 \times (\beta \to -\beta) \right] e^{\epsilon x}
$$

(31)

for the radial eigenfunction (26). Remembering that the quasi-bound configurations of the charged massive scalar fields in the charged Reissner-Nordström black-hole spacetime are characterized by exponentially decaying radial eigenfunctions at spatial infinity [see Eqs. (10) and (11)], one arrives at the important conclusion that the coefficient of the exploding exponent $e^{\epsilon x}$ in the asymptotic spatial expression (31) should vanish:

$$
N_1 \times (2\epsilon)^{-\kappa} \frac{\Gamma(1 - 2\beta)}{\Gamma(\frac{1}{2} - \beta - \kappa)} x^{-1 - \kappa} + N_2 \times (\beta \to -\beta) = 0.
$$

(32)

Finally, substituting the normalization constants (30) into (32), one obtains the (rather cumbersome) resonance equation \cite{9}

$$
\left[ \frac{\Gamma(2\beta)}{\Gamma(-2\beta)} \right]^2 \frac{\Gamma(\frac{1}{2} - \beta - ik) \Gamma(\frac{1}{2} - \beta + \kappa)}{\Gamma(\frac{1}{2} - \beta - \kappa) \Gamma(\frac{1}{2} + \beta + ik - i\omega)} = (2\epsilon)^{2\beta}
$$

(33)

for the complex frequency spectrum $\{\omega(\mu, q, l, M, Q; n)\}$ which characterizes the quasi-bound state resonances of the linearized charged massive scalar fields in the near-extremal charged Reissner-Nordström black-hole spacetime.

The assumption $0 < \beta \in \mathbb{R}$ \cite{28} implies the strong inequality

$$
\delta \equiv (2\epsilon \tau)^{2\beta} \ll 1 \quad \text{for} \quad \tau \to 0
$$

(34)

in the low-temperature $\tau \to 0$ limit. In this regime of near-extremal ($\tau \to 0$) black holes, the discrete resonant solutions of Eq. (33) can be expressed in the compact form

$$
\omega_n \equiv k - i(n + \frac{1}{2} + \beta - \eta \cdot \delta) \quad ; \quad 0 \leq n \in \mathbb{Z}.
$$

(35)
The dimensionless constant $\eta$ in (35) can be determined by substituting the leading order expansion (see Eq. 6.1.34 of [33])

$$\frac{1}{\Gamma\left(\frac{1}{2} + \beta + ik - i\varpi\right)} = (-1)^n n! \eta \cdot \delta + O(\delta^2)$$  \hspace{1cm} (36)

into the l.h.s of the resonance equation (33). This yields

$$\eta = \frac{\mathcal{F}}{(-1)^n n!}$$  \hspace{1cm} (37)

where [see Eq. (33)]

$$\mathcal{F} = \left[\frac{\Gamma(-2\beta)}{\Gamma(2\beta)}\right]^2 \frac{\Gamma\left(\frac{1}{2} + \beta - ik\right)\Gamma\left(\frac{1}{2} + \beta - \kappa\right)}{\Gamma\left(\frac{1}{2} - \beta - ik\right)\Gamma\left(\frac{1}{2} - \beta - \kappa\right)}.$$

IV. SUMMARY

In summary, in this paper we have studied analytically the quasi-bound state resonances of charged massive scalar fields in the near-extremal charged Reissner-Nordström black-hole spacetime. These characteristic resonant modes of the composed black-hole-field system are characterized by the physically motivated boundary condition of purely ingoing waves at the black-hole horizon and asymptotically decaying (bounded) radial eigenfunctions at asymptotic spatial infinity.

Solving the Klein-Gordon wave equation for the linearized charged massive scalar fields in the near-extremal ($MT_{BH} \rightarrow 0$) charged black-hole spacetime, we have derived the compact analytical formula [see Eqs. (9), (12), (13), (14), (34), and (35)] [35]

$$\omega_n = \omega_c + 2\pi T_{BH} \cdot \left\{ qQ - i \left[ n + \frac{1}{2} + \sqrt{(l + 1)^2/2} + M^2(\mu^2 - q^2) \right] + O(MT_{BH}, \delta) \right\} ; \quad n = 0, 1, 2, ...$$  \hspace{1cm} (39)

for the complex resonant spectrum which characterizes the quasi-bound state configurations of the composed Reissner-Nordström-black-hole-charged-massive-scalar-field system.

We shall use natural units in which $G = 1$. Here $M$ and $Q$ are respectively the mass and electric charge of the central Reissner-Nordström black hole. The integer parameters $\ell$ and $m$ are the familiar discrete eigenvalues of the angular spherical harmonic functions $Y_{\ell m}(\theta, \phi)$ which characterize the scalar field mode. We shall henceforth omit these harmonic indices for brevity.

Note that $\mu$ and $q > 0$ for $\mu > h$ and $q > h$, respectively. Hence, these physical parameters of the charged massive scalar fields have the dimensions of (length)$^{-1}$. Here the integer parameters $\ell$ and $l \geq |m|$ are respectively the azimuthal harmonic index and the spherical harmonic index which characterize the scalar field mode. We shall henceforth omit these harmonic indices for brevity.

The integer parameters $\ell$ with $l = 0, 1, 2, ...$ are the familiar discrete eigenvalues of the angular spherical harmonic functions $S_{\ell m}(\theta)$. This fact allows one to match these mathematical solutions in the overlap radial region of purely ingoing waves at the outer black-hole horizon.

Here $\ell (l + 1)$ with $l = 0, 1, 2, ...$ are the familiar discrete eigenvalues of the angular spherical harmonic functions $S_{\ell m}(\theta)$.
