Do solar system experiments constrain scalar–tensor gravity?

Abstract It is now established that, contrary to common belief, (electro-)vacuum Brans–Dicke gravity does not reduce to general relativity (GR) for large values of the Brans–Dicke coupling $\omega$. Since the essence of experimental tests of scalar–tensor gravity consists of providing lower bounds on $\omega$, in light of the misguided assumption of the equivalence between the limit $\omega \to \infty$ and the GR limit of Brans–Dicke gravity, the parametrized post-Newtonian (PPN) formalism on which these tests are based could be in jeopardy. We show that, in the linearized approximation used by the PPN formalism, the anomaly in the limit to general relativity disappears. However, it survives to second (and higher) order and in strong gravity. In other words, while the weak gravity regime cannot tell apart GR and $\omega \to \infty$ Brans–Dicke gravity, when higher order terms in the PPN analysis of Brans–Dicke gravity are included, the latter never reduces to the one of GR in this limit. This fact is relevant for experiments aiming to test second order light deflection and Shapiro time delay.

1 Introduction

Deviations from Einstein’s theory of gravity, general relativity (GR), appear in virtually all attempts to introduce quantum corrections to gravity [1–8] (for recent overviews of GR and the challenges it faces, see, e.g., [9–11]). In addition to these deviations (in the form of extra fields, higher order terms in the field equations, and non-minimal couplings to the curvature), compelling motivation to investigate alternatives to GR comes from the 1998 discovery that the current expansion of the universe is accelerated. Within the standard $Λ$-Cold Dark Matter ($Λ$CDM) model of cosmology based on GR, one needs to introduce a completely ad hoc dark energy with a very exotic equation of state to explain the cosmic acceleration [12]. A popular alternative to dark energy consists of modifying gravity at large scales. Many modifications of GR have been proposed, the most studied being $f (R)$ gravity [13,14]. This is a class of theories in which the Einstein–Hilbert Lagrangian density $R$ (the Ricci scalar of spacetime) is promoted to a non-linear function $f (R)$. It turns out [15–17] that this class of theories reduces to a Brans–Dicke theory with Brans–Dicke scalar $\phi = f' (R)$, vanishing Brans–Dicke coupling parameter $\omega$, and the complicated potential $V (\phi) = R f'' (R) - f' (R) |_{R=R(\phi)}$ (see Refs. [15–17] for reviews and [18] for extensions of $f (R)$ gravity).

Brans–Dicke theory, originally introduced in Refs. [19–21] to account for Mach’s principle, has been generalized to the wider class of scalar–tensor theories [22–24] described by the action (we follow the notation of Ref. [25] and use units in which Newton’s constant $G$ and the speed of light $c$ are unity)

$$S_{\mathrm{ST}} = \frac{1}{16\pi} \int d^4 x \sqrt{-g} \left[ \phi R - \frac{\omega (\phi)}{\phi} \nabla^c \phi \nabla_c \phi - V (\phi) \right] + S^{(m)},$$

where the Brans–Dicke scalar $\phi$ corresponds approximately to the inverse of the gravitational coupling strength $G_{\mathrm{eff}}, \omega$ is the Brans–Dicke coupling, and $V (\phi)$ is a potential for $\phi$, which gives a range to this field. $S^{(m)}$ is the matter action. Besides containing the cosmologically motivated class of $f (R)$ theories, scalar–tensor gravity, which adds only a (massive) scalar degree of freedom $\phi \simeq G_{\mathrm{eff}}^{-1}$ to the massless spin two graviton of GR, constitutes a minimal modification of GR and is the prototype of the alternative theory of gravity [26–28]. The field equations are [21–24]

$$R_{ab} - \frac{1}{2} g_{ab} R = \frac{8\pi}{\phi} \left( T_{ab}^{(m)} + \frac{\omega}{\phi^2} \left( \nabla_a \phi \nabla_b \phi - \frac{1}{2} g_{ab} \nabla^c \phi \nabla_c \phi \right) + \frac{1}{\phi} (\nabla_a \nabla_b \phi - g_{ab} \Box \phi) - \frac{V}{2\phi} g_{ab} \right).$$
\[ \square \phi = \frac{1}{2 \omega + 3} \left( \frac{8 \pi T^{(m)}}{\phi} + \phi \frac{d V}{d \phi} - 2V - \frac{d \omega}{d \phi} \nabla^c \nabla_c \phi \right), \tag{3} \]

where \( R_{ab} \) is the Ricci tensor and \( \nabla_a \) is the covariant derivative of the spacetime metric \( g_{ab} \), while \( T^{(m)} = g^{cd} T^{(m)}_{cd} \) is the trace of the matter energy-momentum tensor \( T^{(m)}_{ab} = -\frac{2}{\sqrt{-g^{(m)}}} \frac{\delta S^{(m)}}{\delta g^{(m)}_{ab}} \).

Scalar–tensor gravity in the Jordan frame (\( g_{ab}, \phi \)), can be reformulated in the Einstein conformal frame \( (\tilde{g}_{ab}, \tilde{\phi}) \) as follows [21]. Perform the conformal transformation of the metric tensor

\[ g_{ab} \rightarrow \tilde{g}_{ab} = \phi g_{ab}, \tag{4} \]

and the scalar field redefinition

\[ d\tilde{\phi} = \sqrt{\frac{2\omega + 3}{16\pi}} \frac{d\phi}{\phi}. \tag{5} \]

Since we restrict ourselves to Brans–Dicke theory with constant \( \omega \), we have the non-linear scalar field redefinition

\[ \phi \rightarrow \tilde{\phi} = \sqrt{\frac{|2\omega + 3|}{16\pi}} \ln \left( \frac{\phi}{\phi_0} \right), \tag{6} \]

where \( \phi_0 \) is an integration constant and \( \omega \neq -3/2 \). Both \( \phi \) and \( g_{ab} \) depend on the parameter \( \omega \), therefore the Einstein frame metric \( \tilde{g}_{ab} \) in general depends on the parameter \( \omega \) (the same is true, in general, for the Einstein frame scalar \( \tilde{\phi} \)).

Using the Einstein frame variables \( (\tilde{g}_{ab}, \tilde{\phi}) \), the Brans–Dicke action (1) (with \( \omega = \text{const.} \)) is rewritten as

\[ S_{BD} = \int d^4x \sqrt{-\tilde{g}} \left[ \frac{\tilde{R}}{16\pi} - \frac{1}{2} \tilde{g}^{ab} \tilde{\nabla}_a \tilde{\phi} \tilde{\nabla}_b \tilde{\phi} - U(\tilde{\phi}) + \frac{\mathcal{L}^{(m)}}{\tilde{\phi}^2(\tilde{\phi})} \right], \tag{7} \]

where

\[ U(\tilde{\phi}) = \frac{V(\phi)}{16\pi \tilde{\phi}^2} \bigg|_{\phi=\tilde{\phi}(\tilde{\phi})}, \tag{8} \]

where we denote Einstein frame quantities with a tilde. Formally, this is the Einstein–Hilbert action of GR with a matter scalar field with canonical kinetic energy density, but this scalar \( \tilde{\phi} \) now couples non-minimally to matter. In the Einstein frame, the Brans–Dicke field equations become

\[ \tilde{R}_{ab} - \frac{1}{2} \tilde{g}_{ab} \tilde{R} = 8\pi \left( \frac{64\pi \tilde{\phi}}{m^4} T^{(m)}_{ab} + \tilde{\nabla}_a \tilde{\phi} \tilde{\nabla}_b \tilde{\phi} - \frac{1}{2} \tilde{g}_{ab} \tilde{g}^{cd} \tilde{\nabla}_c \tilde{\nabla}_d \tilde{\phi} - U(\tilde{\phi}) \tilde{g}_{ab} \right), \tag{9} \]

\[ \tilde{g}^{ab} \tilde{\nabla}_a \tilde{\phi} \tilde{\nabla}_b \tilde{\phi} - \frac{dU}{d\tilde{\phi}} + 8 \sqrt{\frac{2\omega + 3}{2\omega + 3}} \left( -\frac{64\pi \tilde{\phi}}{m^4} \mathcal{L}^{(m)} \right) = 0. \tag{10} \]

From now on we restrict to vacuum Brans–Dicke theory and set \( T^{(m)}_{ab} = 0 \). The explicit coupling between Einstein frame scalar \( \tilde{\phi} \) and matter then disappears and the Einstein frame action (7) is formally the Einstein–Hilbert action and the Einstein frame pair \( (\tilde{g}_{ab}, \tilde{\phi}) \) is formally a scalar field solution of the Einstein equations even though it has been generated by the original Jordan frame spacetime \( (g_{ab}, \phi) \).

\section*{2 $\omega \rightarrow \infty$ vs. GR limit}

In practice, Brans–Dicke theory with $\omega = \text{const.}$ is used to approximate all scalar–tensor theories in experimental tests of gravity in the weak field regime [26–28] (this situation can be different in strong gravity when scalarization is involved, but we are not concerned with this type of situation here). It is clear that Brans–Dicke gravity reduces to GR if $\phi$ becomes constant. Precisely, the GR limit of Brans–Dicke gravity is understood as the limit in which Brans–Dicke gravity coupled to matter reduces to GR sourced by the same type of matter.

The belief that $\phi$ does so in the limit $\omega \rightarrow \infty$ is standard textbook material (e.g., [29]). However, the asymptotics of $\phi$ in this limit are important. While in most cases these asymptotics are $\phi = \phi_\infty + \mathcal{O}(1/\omega)$, where $\phi_\infty$ is a constant [29], many analytic solutions of the Brans–Dicke field equations have been discovered over the years for which $\phi = \phi_\infty + \mathcal{O}(1/\sqrt{|\omega|})$, which do not go over to the corresponding GR solutions with the same form of matter [30–37]. Far from being limited to a few maverick solutions, this problem has later been shown to affect the entire electrovacuum (i.e., $T^{(m)} = 0$) theory [43] and a formal explanation has been given for this “anomalous” behaviour [43–45].

Deviations from GR are well constrained experimentally in the Solar System, where gravity is weak, and to some extent also outside of it [26–28, 46, 47]. Assuming the Brans–Dicke field to be long-ranged, the best limits on scalar–tensor gravity arise from the Cassini probe and are $|\omega| > 40,000$ [48]. In general, experiments provide a lower bound on $|\omega|$, constraining this parameter to be large (unless $\phi$ becomes so massive and short-ranged to escape this limit, as in viable $f(R)$ models [15–17]).

The Solar System experiments probe gravity in vacuo, the situation in which the $\omega \rightarrow \infty$ limit is anomalous. Therefore, how can experiments constraining the deviations from GR in the field of the Sun and forcing $|\omega|$ to be large, apply to a theory that does not reduce to GR in this limit? Can the parametrized post-Newtonian (PPN) approximation, which constitutes the basis for analyzing these experiments [26–

\footnote{Similar anomalies are occasionally reported for instances of Brans–Dicke solutions with non-conformal matter [38–42].}
28,49–51], still discriminate between GR and Brans–Dicke
gravity in the large \( \omega \) regime?

This question is crucially important for experimental tests
of scalar–tensor gravity, but it has not been posed in the lit-
terature thus far. Here we provide an answer: the exact (strong
gravity) electrovacuum theory definitely does not reduce to
GR as \( \omega \to \infty \). In this limit, a (canonical, minimally cou-
pled) scalar field survives in the limit of the field equations
and acts as a matter source \([52,53]\). However, the PPN analy-
sis is limited to the weak field expansion of these field equa-
tions and, in this regime, the offending terms disappear from
these equations, in which the dominant terms introduced by
the scalar degree of freedom \( \phi \) conform, instead, to the usual
PPN analysis. This simplification occurs only to first order in
the deviations of the metric and Brans–Dicke scalar from the
Minkowski background, and are bound to reappear to second
order [54–57].

Now to the technical details. It is clear that, if the Brans–
Dicke scalar becomes constant, Brans–Dicke gravity reduces
to GR and therefore one should recover \( \phi \to \text{const.} \) as \( \omega \to \infty \).
The rate at which \( \phi \) approaches a constant is important.
The gradient \( \nabla \phi \) decays as \( |\omega| \) becomes larger,
\[
\nabla_u \phi = \phi_0 \sqrt{\frac{16\pi}{2\omega + 3}} \exp \left( \sqrt{\frac{16\pi}{2\omega + 3}} \phi \right) \nabla_u \tilde{\phi}.
\]
\( \text{(11)} \)

Consider the Jordan frame field equations and, in particular,
the term which appears in their right hand side
\[
A_{ab} \equiv \frac{\omega}{\phi^2} \left( \nabla_u \phi \nabla_v \phi - \frac{1}{2} g_{ab} \nabla^c \phi \nabla_c \phi \right).
\]
\( \text{(12)} \)

In the literature, the failure of Jordan frame Brans–Dicke the-
ory to reproduce the expected GR limit (which corresponds
to \( \phi = \text{const.} \) and to the vanishing of the right hand side
of the vacuum field equations) has been recognized to fol-
low from the fact that, when the asymptotics is given by
\( \phi = \phi_\infty + O(1/\sqrt{|\omega|}) \), the tensor \( A_{ab} \) does not vanish in the
\( \omega \to \infty \) limit but remains of order unity [30–36,43]. It is
easy to see that, when Eq. (11) is true, the tensor \( A_{ab} \) reads
\[
A_{ab} = \frac{\omega}{\phi^2} \phi_0^2 e^{\frac{16\pi}{2\omega + 3}} \phi \left( \frac{16\pi}{2\omega + 3} \phi \right)^{1/2} \left( \nabla_u \phi \nabla_v \phi \right)
- \frac{1}{2} g_{ab} \nabla^c \phi \nabla_c \phi
= 16\pi \text{sign}(\omega) \left( \frac{\omega}{2\omega + 3} \phi \right)^{1/2} e^{\frac{16\pi}{2\omega + 3} \phi} \left( \nabla_u \phi \nabla_v \phi \right)
- \frac{1}{2} \tilde{g}_{ab} \phi \tilde{g}^{cd} \nabla_c \tilde{\phi} \nabla_d \tilde{\phi}.
\]
\( \text{(13)} \)

for all values of the parameter \( \omega \). Now, in the limit \( \omega \to \infty \)
in which \( \phi \to \phi_0 \), one obtains
\[
A_{ab} \to A^{(\infty)}_{ab} = 8\pi \text{sign}(\omega) \left( \tilde{\nu}_a \tilde{\phi} \tilde{\nu}_b \tilde{\phi} - \frac{1}{2} \tilde{g}_{ab} \tilde{g}^{cd} \tilde{\nu}_c \tilde{\phi} \tilde{\nu}_d \tilde{\phi} \right).
\]
\( \text{(15)} \)

The Einstein frame metric \( \tilde{g}^{(\infty)}_{ab} \) solves the Einstein equations
with the scalar field \( \phi \) as the only matter source. This field
has canonical stress–energy tensor \( A^{(\infty)}_{ab} \), which is obtained
as the limit of the Jordan frame stress–energy tensor, as
\[
8\pi \tilde{T}^{(\infty)}_{ab}[\tilde{\phi}]_{\text{Einstein frame}} = A^{(\infty)}_{ab} \quad \text{Jordan frame limit}
\]
\( \text{(16)} \)

For \( \omega > 0 \), this Einstein frame scalar couples minimally to
the curvature and has canonical kinetic energy density. One
obtains the same metric tensor by considering two candi-
dates for a GR limit of Brans–Dicke theory: the \( \omega \to \infty \)
limit of the Einstein frame metric and the \( \omega \to \infty \) limit of
the Jordan frame metric, which coincide apart from an
irrelevant positive multiplicative constant \( \phi_\infty \). However, this
metric \( \tilde{g}^{(\infty)}_{ab} = g_{ab} \) obtained with these two different meth-
ods is not a solution of the vacuum Einstein equations (this
would require instead \( A^{(\infty)}_{ab} \) to vanish identically). Instead,
\( g^{(\infty)}_{ab} = g_{ab} \) solves the coupled Einstein–Klein–Gordon
equations and, therefore, vacuum Brans–Dicke theory does
does not reproduce vacuum GR in the limit, as it should be for
a correct “limit to GR”.

3 PPN analysis and Brans–Dicke anomaly

It is well known that the only stationary, spherically sym-
metric, asymptotically flat black hole solution of Brans–Dicke
gravity with \( V(\phi) = 0 \) is the Schwarzschild metric [58–61].
If one assumes the absence of an event horizon, however, the
most general static, spherically symmetric, asymptoti-

cally flat solution of the vacuum Brans–Dicke field equations
with vanishing potential is parametrized by three continuous
real parameters \( (\alpha_0, \beta_0, \gamma) \) (see, e.g., [62,63] and references
therein). In detail, for \( \gamma \neq 0 \) the general solution reads
\[
dx^2 = -e^{(\alpha_0 + \beta_0)/r} dt^2 + e^{(\beta_0 - \alpha_0)/r} \left( \frac{\gamma}{r \sinh(\gamma/r)} \right)^4 d\sigma^2
+ e^{(\beta_0 - \alpha_0)/r} \left( \frac{\gamma}{r \sinh(\gamma/r)} \right)^2 r^2 d\Omega^2_{(2)},
\]
\( \text{(17)} \)
\[
\phi(r) = \phi_0 e^{-\beta_0/r} \quad \beta_0 = \frac{\sigma}{\sqrt{2|\omega + 3|}}.
\]
\( \text{(18)} \)

where \( d\Omega^2_{(2)} \equiv d\theta^2 + \sin^2 \theta d\phi^2 \), \( \sigma \) denotes a scalar charge,
and \( 4 \gamma^2 = \alpha_0^2 + 2\sigma^2 \). If instead \( \gamma = 0 \), the solution is
given by the Brans class IV spacetime \([62,64]\) \footnote{The last condition only holds for \( \gamma > 0 \) and there is no loss of
generality in choosing \( \gamma > 0 \) when \( \gamma \neq 0 \).}
\[ ds^2_{(0)} = -e^{(\omega_0 + \beta_0)/r} \, dt^2 + e^{(\beta_0 - \omega_0)/r} \left( dr^2 + r^2 d\Omega^2_{(2)} \right), \]  
\[ \phi(r) = \phi_0 \, e^{-\beta_0/r}. \]  

It is easy to see that, for this class of solutions, the scalar field approaches a constant value \( \phi_\infty = \phi_0 \) in the limit \( \omega \to \infty \) as 
\[ \phi(r) \sim \phi_0 - \frac{\phi_0 \sigma}{\sqrt{2|\omega|} \, r} + O \left( \frac{1}{|\omega|} \right), \]  
which is indeed the typical behavior for which the anomaly comes up.

Now, for \( \omega \to \infty \), Eq. (17) reduces to the Fisher–Janis–Newman–Winicour–Buchdahl–Wyman metric in the limit, which is known to be the general static, spherical, asymptotically flat solution for the vacuum Einstein field equations (namely the Minkowski space, since we have assumed the absence of event horizons). Instead, this family of solutions approaches two families of spacetimes corresponding to non-vacuum solutions of the Einstein field equations, thus breaking the equivalence between the GR limit of Brans–Dicke gravity and the limit \( \omega \to \infty \).

It is then interesting to see how the PPN analysis of scalar–tensor theories is affected by this anomalous behavior. Using the wisdom coming from the general static, spherical, asymptotically flat non-black-hole class of solutions of vacuum Brans–Dicke gravity one can show that, whilst the equivalence of the two limits is not affected at the first post-Newtonian order, an effective scalar field stress–energy tensor survives at the next-to-leading order in the \( \omega \to \infty \) limit. This, in turn, prevents the full Brans–Dicke theory from reducing to GR in this limit.

In the weak field limit the metric and scalar field are expanded as 
\[ g_{\mu\nu} = \eta_{\mu\nu} + h_{\mu\nu}, \]  
\[ g^{\mu\nu} = \eta^{\mu\nu} - h^{\mu\nu} + \frac{1}{2} h^{\mu\alpha} h^{\nu}_{\alpha} + O(h^3), \]  
\[ \phi = \phi_0 + \varphi^2 + \frac{1}{2} + O(\varphi^3), \]  
where \( \eta_{\mu\nu} \) is the Minkowski metric and \( \phi_0 \) is a constant, while \( h_{\mu\nu} \) and \( \varphi \) are small perturbations. From Eqs. (17) and (19) one infers that 
\[ h_{\mu\nu} \sim \frac{\alpha_0 + \beta_0}{r} \]  
in the weak field limit. Besides, since \( \beta_0 \sim \sigma / \sqrt{2|\omega|} \) for large \( \omega \), one can conclude that 
\[ h_{\mu\nu} \sim \frac{\alpha_0}{r} \pm \sigma \frac{1}{\sqrt{2|\omega|} \, r} \]  
as \( \omega \to \infty \), which further implies that the anomaly does not show up in the weak field expansion of the left hand side of Eq. (2) since this contains only positive powers of \( h_{\mu\nu} \) and its derivatives. However, the right hand side of Eq. (2) for \( V(\phi) = 0 \) and in \( \text{vacuo} \) has a peculiar behavior. Indeed, expanding this term up to third order one finds 
\[ \frac{\omega}{\phi^2} \left( \partial_\mu \phi \partial_\nu \phi - \frac{1}{2} g_{\mu\nu} \partial_\alpha \phi \partial^\alpha \phi \right) + \nabla_\mu \partial_\alpha \phi \]  
\[ = \frac{\omega}{\phi_0^2} \left( \partial_\mu \phi \partial_\nu \phi - \frac{1}{2} \eta_{\mu\nu} \partial_\alpha \phi \partial^\alpha \phi \right) \]  
\[ + \frac{1}{\phi_0^2} \left[ \partial_\mu \partial_\nu \phi + \partial_\mu \partial_\alpha (\varphi^2 / 2) \right] \]  
\[ + (\partial_\mu h_{\nu\alpha} + \partial_\nu h_{\mu\alpha} - \partial_\alpha h_{\mu\nu}) \partial^\alpha \phi \]  
\[ + O(\varphi^3, h \varphi^2, h^2 \partial \phi). \]

Now, assuming that we work within the scenario that leads to the exact solutions discussed above and using the asymptotics (21) and (25) it is easy to see that, while at the first post-Newtonian order the scalar field contribution disappears, to second order in the PPN expansion the first term in the left hand side of Eq. (26) is \( O(\omega^0) \) and survives the limit \( \omega \to \infty \), breaking the equivalence between these two limits.

Let us now make more quantitative predictions using the line element (17) as an example. First, in (17) one identifies the areal radius 
\[ R(r) = e^{(\beta_0 - \omega_0)/2r} \frac{\gamma / r}{\sinh(\gamma / r)} \, r. \]

Expanding for large \( r \), one finds 
\[ R = r + \frac{\beta_0 - \omega_0}{2} + \frac{3(\beta_0 - \omega_0)^2 - 4 \gamma^2}{24 r} + O \left( \frac{1}{r^2} \right), \]
that implies 
\[ dr^2 \simeq \left( 1 + \frac{3(\beta_0 - \omega_0)^2 - 4 \gamma^2}{12 r^2} \right) dR^2. \]

Hence one can implicitly recast the line element (17) in terms of the areal radius as 
\[ ds^2_{\mu \neq 0} = g_{tt} \, dt^2 + g_{RR} \, dR^2 + R^2 \, r^2 \, d\Omega^2_{(2)}, \]
with 
\[ g_{tt} = -e^{(\omega_0 + \beta_0)/r} \]  
\[ = - \left( 1 + \frac{\alpha_0 + \beta_0}{r} + \frac{(\alpha_0 + \beta_0)^2}{2r^2} \right) + O \left( \frac{1}{r^3} \right), \]
Performing the usual PPN identifications

\[ g_{tt} = -(1 + 2 \Psi(r)) \quad \text{and} \quad g_{RR} = 1 + 2 \Phi(r), \quad (33) \]

the post-Newtonian parameter \( \gamma_{\text{PPN}} \) (not to be confused with \( \gamma \)) reads

\[
\gamma_{\text{PPN}} = -\frac{\Psi(r)}{\Phi(r)} = \frac{\alpha_0 + \beta_0}{\alpha_0 - \beta_0} \left( 1 + \frac{5\alpha_0^2 - 6\alpha_0\beta_0 + \beta_0^2 - 4\gamma^2}{4(\alpha_0 - \beta_0) r} \right) + O\left( \frac{1}{r^2} \right). \quad (34)
\]

Taking the limit \( \omega \to \infty \) (i.e. \( \beta_0 \to 0 \)), one finds

\[
\lim_{\omega \to \infty} (\gamma_{\text{PPN}} - 1) = \frac{5\alpha_0^2 - 4\gamma^2}{4\alpha_0 r} + O\left( \frac{1}{r^2} \right), \quad (35)
\]

which is always non-vanishing when the scalar charge \( \sigma \neq 0 \).

### 4 Conclusions

As a conclusion, the PPN analysis narrowly escapes the problem of the GR limit arising in the full theory. It is clear, however, that this problem will reappear as soon as second and higher order terms are included in the weak field expansion and, of course, in the full strong gravity regime. To second order, the PPN analysis of scalar–tensor gravity is in jeopardy. The divergence between PPN predictions and the \( \omega \to \infty \) limit of Brans–Dicke theory will then be relevant. In particular, this divergence will become important in the experimental determination of light deflection by the gravitational field of the Sun to second order in the PPN expansion [54–57]. These deviations could be obtained, in principle, with high precision astrometry, in testing strong gravity effects with the Event Horizon Telescope [65, 66] and, potentially, in tests based on gravitational waves [67–72]. Such strong gravity effects, which look more promising for detecting scalar–tensor gravity effects or further constraining the theory, will be explored in future work.

\[ ^3 \text{Note that for large values of } r \text{ one has } R \simeq r. \]
