ABSTRACT

The main goal of this study is to compare reactivity and stability of eugenol (1), methyl eugenol (2), and eugenyl acetate (3) in sulfonation reaction to produce new fused ring sultone derivatives. Isolated eugenol can be easily derivatised to methyl eugenol (2) and eugenyl acetate (3) using dimethyl sulfate and acetate anhydride respectively. Eugenol (1), methyl eugenol (2), and eugenyl acetate (3) separately react with chlorosulfuric acid to produce new fused ring sultone derivatives in different yields. Methyl eugenol (2) gave a more stable product compare to eugenol (1) and eugenyl acetate (3).

Keywords: Reactivity, Stability, Eugenol, Methyl Eugenol, Eugenyl Acetate, Fused Ring Sultone

INTRODUCTION

A functional group or substituent is a specific moiety that is responsible for the biological, physical, chemical properties of the compound. The character and identity of the compound depend on the functional groups, structurally eugenol, methyl eugenol, and eugenyl acetate are only different in their functional group attached at 1 position. The compounds have –OH, -OMe, and –OCOMe functional groups respectively (Fig.-1).

Cloves (Syzygium aromaticum) are a well known plant source of eugenol and contained about 70-96% of eugenol. Eugenol shows widely biological activities such as anticancer, antimicrobial, antioxidant, anti-inflammatory, antibacterial, acaricidal, dental caries, and antitumor. Eugenol (1) has been used as a starting material for organic synthesis. Eugenol can be easily transformed into methyl eugenol and eugenyl acetate. Methyl eugenol also exhibits antifungal, antibacterial, nematicidal, antiinflammation, anticancer, and food flavouring, while eugenyl acetate demonstrates antimicrobial and toxic against Artemia salina.

Eugenol and its methyl, acetyl derivatives undergo substitution reaction due to the presence of benzene ring and also undertake addition reaction due to occupancy of alkene moiety. Eugenol (1) and its methyl, acetyl derivatives are compound alike to benzene with hydroxyl, methoxyl, acetyl, and alkene substituents and the substituents lead the regioselectivity for further reaction. The presence of alkene substituent at the terminal of allyl moiety will undergo Markovnikov addition reaction by strong acids such as

Rasayan J. Chem., 13(2), 1193-1198(2020)

chlorosulfonic acid and produce sultone derivatives. Sultones are widely used in industry and having commercial application in detergents, polymers, antistatics. Synthesis of sultone is not remarkable progress and only few are reported.

EXPERIMENTAL

Materials
The cloves were bought from Gangga, West Lombok of Indonesia. The reagent and chemicals were gained from Merck and Sigma included: 3 solvents (hexane, dichloromethane, and methanol), eugenol standard, sodium carbonate anhydrous, sodium hydroxide pellet, chlorosulfonic acid, dimethyl sulfate, acetate anhydride, silica gel 40-60 mesh for chromatography, and aluminium sheet thin layer chromatography (TLC).

Instruments
The chromatograms of GC-MS were obtained on Shimadzu QP-2010 Ultra. The spectra of $^1$H NMR were obtained in CDCl$_3$ on a Bruker spectrometer (400 MHz).

Extraction and Isolation of Eugenol (1)
Powder of clove (50g) was extracted with dichloromethane for 48 hours to provide oil (19.5 g, 39%). Chromatography was used to purify eugenol (1) (7.80 g) (78%) and identified by GC-MS analyses, M$^+$ 164, calculated for C$_{10}$H$_{12}$O$_2$. Fragments: 149 (M$^+$ – CH$_3$), 131, 121, 103, 91, 77 (C$_6$H$_6$, base peak); $^1$H NMR: 3.81 (3H, s, Aromatic -OCH$_3$), 5.05 (2H, m, =CH$_2$), 5.53 (2H, m, Aromatic -OH and -HC=), 5.91(2H, m, -CH$_2$-), 6.66 (1H, s, Aromatic H), 6.67 (1H, d, Aromatic H), 6.82 (1H, d, Aromatic H), and also confirmed by TLC of eugenol standard.

Preparation of Methyl Eugenol (2)
Three necks round-bottomed flask (100 mL) and fit-out with a condenser was filled with eugenol (5 g) and sodium hydroxide (2 g in 20 mL of distilled water) and further stirred (15 min.). Dimethyl sulfate (4.0 mL) was added drop by drop and stirring (30 min.) and refluxed at 103°C (1 h.), and after worked up to give an oil (86.58%). GC-MS gave molecular ion (M$^+$ 178, calculated for C$_{11}$H$_{14}$O$_2$). Fragmentations: 163 (M$^+$ - CH$_3$), 147 (M$^+$ – OCH$_3$), 135, 115, 107, 91, 77 (C$_6$H$_6$). $^1$HNMR: 3.77(3H, s, Aromatic -OCH$_3$), 3.83 (3H, s, Aromatic -OCH$_3$), 5.05 (2H, m, =CH$_2$), 5.50 (1H, m, -HC=), 5.91(2H, m, -CH$_2$-), 6.66 (1H, s, Aromatic H), 6.67 (1H, d, Aromatic H), and 6.82 (1H, d, Aromatic H).

Preparation of Eugenol Acetate (3)
This method was adopted from Sudarma et al. Eugenol (2 g), acetate anhydride (6 g), sodium carbonate (2 g), and ethyl acetate (100 mL) were mixed and stirred (24 h.). The mixture was filtered and evaporated to afford a residue. Water (10 ml) was added and extracted with dichloromethane (25 mL). The dichloromethane layer was dried by sodium carbonate anhydrous and evaporated to afford eugenil acetate (3) (1.1 g, 87.5%). This compound was analyzed by TLC, R$_f$ 0.78 (eluent: CH$_2$Cl$_2$) and GC-MS: M$^+$ 206, calculated for C$_{12}$H$_{14}$O$_3$, fragmentations: 77, 91, 103, 121, 131, 149, 164 (base peak). $^1$HNMR: 2.31 (3H, s, CH$_3$CO$_2$); 3.37 (2H, d); 3.81 (3H, s, OCH$_3$); 5.10 (2H, m); 5.97 (1H,m); 6.77 (2H, m); 6.94 (1H, d).

Synthesis of Sultone (4) from Methyl Eugenol (2)
This method was adopted from Sudarma et al. Methyl eugenol (2) (100 mg) was dissolved in dichloromethane (20 mL) and added drops by drop chlorosulfonic acid (2 mL) with stirring for (30 min.) then refluxed for (15 min.). The dichloromethane was evaporated and added distilled water (10 mL), and adjusted to pH 8 using 1M NaOH, then extracted with dichloromethane (2 x 50 mL). The dichloromethane extract was dried with sodium carbonate anhydrous and evaporated to leave a gum, and recrystallized from methanol to sultone (4) (84%). GC-MS: M$^+$ 258, cal for C$_{11}$H$_{14}$O$_5$, major fragments: 77, 107, 135, 150 (base peak), 179, 243. $^1$H NMR: 6.62 (3H, d, J 6.6 Hz, -CH$_3$); 2.85 – 2.31 (2H, m, -CH$_2$-); 3.83 (3H, s,-OCH$_3$); 3.93 (3H, s, -OCH$_3$); 5.20 (1H, m, -CH-); 6.60 (1H, s, Aromatic H); 7.33(1H, s, Aromatic H).
Synthesis of Sultone (5) from Eugenol (1)
Round bottomed flask (100 mL) and fit-out with a condenser were charged with stirring dichloromethane (50 mL) and eugenol (1g). This solution was added chlorosulfonic acid (10 mL) drops by drop and further stirred at ambient temperature for (30 min.) and refluxed for (15 min.). Work up as synthesis of sultone (4) to give an amorphous grey solid, and recrystallized from methanol to afford sultone (5) (73%). GC-MS gave molecular ion (M⁺ 244), calculated for C₁₀H₁₂SO₅, major fragments: 136 (base peak), 151, 165, 183, 200. ¹H NMR (400.1 MHz, CDCl₃): δ 1.62 (3H, d, J 6.6 Hz, -CH₃); 2.16 (1H, s, OH); 2.85 – 2.31 (2H, m, CH₂); 3.93 (3H, s, -OCH₃); 5.20 (1H, m, -CH-); 6.60 (1H, s, Aromatic H); 7.33 (1H, s, Aromatic H).

Synthesis of Sultone (5) from Eugenyl Acetate (3)
The solution of eugenyl acetate (3) (100 mg) in dichloromethane (20 mL) was filled chlorosulfonic acid (2 mL) drops by drop. The solution was stirred at ambient temperature for (30 min.) then refluxed for (15 min.). Work up as synthesis of sultone (4) to give an amorphous grey solid, and recrystallized from methanol to afford sultone (5) (96%).

RESULTS AND DISCUSSION
Eugenol (1) is a naturally occurring compound that is easily isolated from clove oil and has been used for the synthesis of fused ring sultone derivatives via methyl eugenol (2) or eugenyl acetate (3) (Fig.-2).

Eugenol (1) is aromatic alcohol characterized by the presence of an -OH group and is possibly reduce the yield of sultone (5) (73%) due to its reactivity against electrophilic aromatic substitution, oxidation, etc. The existing of hydroxyl group in eugenol (1) make it can form hydrogen bond and leads to increase boiling points. The presence of a strong base and also semi-polar solvents can deprotonate the hydroxyl group of eugenol (1) and make the difference in electronegativity between the carbon of aromatic ring and the oxygen atoms.

The yield of fused ring sultone derivatives could be increased, presumably by the protection of –OH group of eugenol (1), without protection the yield of sultone derivative (5) is 73% only. Protection of –

SYNTHESIS OF NEW FUSED RING SULTONE
I. M. Sudarma et al.
OH group is one common synthetic strategies, esterification and methylation are two ways to protect it. Eugenol (1) can be easily acylated by acetate anhydride with a catalyst to produce eugenyl acetate (3) in high yield. Chemical transformation of eugenyl acetate (3) using chlorosulfonic acid expected to afford sultone (6), however, it produces sultone (5) in high yield (96%) (Fig.-3).

Eugenol (1) can be easily methylated with dimethyl sulfate to form ether functional group or methyl eugenol (2) in high yield (84%). Sulfonation reaction of this compound with chlorosulfonic acid in the same manner of eugenol (1) and eugenyl acetate (3) leads to the formation of desire product, sultone derivative (4) (84.03%). The chromatogram of GC-MS showed a peak of sultone (4) present at the retention time of 13.031 minutes (Fig.-4).

1H nuclear magnetic resonance confirmed the difference between sultone derivative (4) and (5). Sultone derivative (4) gave two methoxyl groups at δ 3.83 (3H, s, -OCH3) and 3.93 (3H, s, -OCH3) while sultone derivative (5) gave one –OH at δ 2.16 (1H, s, OH) and one methoxyl at δ 3.93 (3H, s, -OCH3).

The product of sulfonation reaction of eugenol (1), methyl eugenol (2), and eugenyl acetate (3) in the same condition was summarized in Table-1.

| Starting Material     | Condition                        | Product (%) |
|-----------------------|----------------------------------|-------------|
| Eugenol (1)           | CISO3H/Dichloromethane, rt. 0.5 h, reflux 15 min | Sultone (5) (73%) |
| Methyl eugenol (2)    | CISO3H/Dichloromethane, rt. 0.5 h, reflux 15 min | Sultone (5) (96%) |
| Eugenyl acetate (3)   | CISO3H/Dichloromethane, rt. 0.5 h, reflux 15 min | Sultone (4) (84%) |

Table-1 showed that sulfonation reaction of eugenol (1), methyl eugenol (2), and eugenyl acetate (3) separately gave significant differences in percent yield of sultone. Eugenol (1) gave in moderate yield
SYNTHESIS OF NEW FUSED RING SULTONE

I. M. Sudarma et al.

(73%) of sultone (5); methyl eugenol (2) produced in high yield (84%) of sultone (4); eugenyl acetate (3) expected to produce sultone (6), however, its produced in high yield (96%) of sultone (5). Acetyl group at sultone (6) was hydrolyzed to form sultone (5) due to the carbonyl of acetyl could be attacked by a strong nucleophile. Different reactivity and stability of eugenol (1), methyl eugenol (2), and eugenyl acetate (3) in sulfonation reaction would give a different yield of sultone derivatives. The –OH of eugenol presumably more reactive or less stable compare to methyl eugenol and eugenyl acetate.

CONCLUSION

Methyl eugenol (2) was more stable compare to eugenol (1) and eugenyl acetate (3) in sulfonation reaction to produce a new fused ring of sultone derivatives (4) and (5).

ACKNOWLEDGMENT

The University of Mataram and The Ministry of Culture and Education, the Republic of Indonesia highly appreciated Research Grant 2019/2020 to support the financing for this research works.
