Introduction: Urinary incontinence (UI) is a significant health concern and has been shown to impair women’s activities and also affects the physical and mental health [1]. Studies on UI have reported a prevalence of 32%-64% for all UI and 40-59% for stress urinary incontinence (SUI) including mixed incontinence [2]. Affected women have poorer health seeking behavior for UI. Approximately 54.3% of all pregnant women have detrimental effects on quality of life [3]. Although, pregnancy is an independent risk factor for UI, irrespective of labor and delivery practices, however, despite the multiple references in literature, the pathophysiological effects of pregnancy and mode of delivery on the pelvic floor and lower urinary tract symptoms remain uncertain [4].

Prenatal physiological changes such as increasing pressure of the advancing gravid uterus and growing fetal weight on pelvic floor muscle (PFM) throughout the pregnancy, along with the pregnancy-related changing levels of hormones such as progesterone, estrogen, and relaxin, may lead to reduced strength and supportive and sphincteric function of PFM [5-8]. PFM weakness causes bladder-neck and urethral mobility, leading to urethral sphincter incompetence. Hence, when intra-abdominal pressure is increased with coughing, sneezing, laughing, or moving, the pressure inside the bladder becomes greater than the urethral closure pressure and the urethral sphincter is not strong enough to maintain urethral closure. Urinary leakage will be the result. In particular, SUI is common during pregnancy and puerperium. After delivery, SUI symptoms resolve in the vast majority of cases [9]. The healing process may take some time after the delivery, but in a significant percentage of women, it can persist in subsequent stages of life [10]. In primipara women, SUI symptoms tend to resolve within 3 month after delivery [11].

Multiple risk factors have been associated with UI. Significant risk factors for UI in pregnancy were maternal age ≥35 years, body mass index and parity [12]. Smoking, diabetes, chronic cough and high intake of caffeine are identifiable risk factors for UI [1 3-15].
The information available on UI in postpartum women from India is sparse. Therefore, a study on UI is designed which would add information regarding prevalence of UI in this part of world as incidence and prevalence estimates of incontinence vary widely. Only a few population based studies have investigated prevalence of urinary incontinence during pregnancy by type and severity [16]. Also, data on risk factors for incontinence in pregnancy are scarce.

Material and Methods

This observational study was carried out over six weeks in the department of obstetrics and gynecology, at a tertiary care hospital in Northern India. All the healthy postpartum women admitted in the post natal ward, who had singleton pregnancy, were included in the study. Total 500 subjects were included in the study. Informed consent was obtained from the participants prior to conducting the study and the women were interviewed about the given questionnaire.

Definitions

Urinary incontinence was assessed using standardized questions based on questions validated in previous studies [17,18]. The questionnaire covered the risk factors, symptoms and severity of the UI. Women who had leakage of urine at least once a month, regardless of amount were defined as UI. Women were defined as having stress urinary incontinence if leakage of urine was associated with coughing, laughing, sneezing or physical activity, urge incontinence, if leakage was preceded or accompanied by urgency, and mixed incontinence when symptoms of both stress (SUI) and urge (UUI). Urinary incontinence were present. These definitions follow the standardized terminology for lower urinary tract symptoms endorsed by the International Continence Society [19]. Severity of UI was assessed as slight, moderate or severe based on the frequency and amount of leakage using the incontinence severity index [17,18]. The questionnaire was used to gather information about socio-demographic pattern, predisposing and risk factors, health seeking behavior including the prevalence of UI. Data analysis was done using SPSS version 20. Odd’s ratio and chi-square test was used for univariate analysis.

Observations and Results

During the study, 500 women were interviewed. The mean age of study population was 25.1 years with a range of 19-40 years. The demographic characteristics like age, weight, height, BMI, parity and past delivery mode were not found to have a significant association with UI (Table 1).

Out of 500 participants, 185 primipara participated in study and of those 185 participants, 81 subjects reported incontinence. The prevalence of incontinence was 43.7% in primipara. Similarly, 315 multipara took part in the study and 163 had incontinence which gives a prevalence of 53.4% in multipara women.

In the study population chronic cough (p=0.001) and bladder infections (p=0.013) had significant association with UI. Table 2 shows p value and odds ratio for the risk factors. Out of 500 women 202 reported incontinence, thus giving a prevalence of 40.4%, out of that 192 (45.5%) had SUI, 40(19.8 %) had UUI and 70 (34.6%) had mixed incontinence. Among the incontinent women 31/202 (15.3%) sought treatment. The treatment seeking behavior was not related to severity of UI (Table 3) (Figure 1).

Table 1: Study Group Characteristics.

| Characteristics                  | Group I (n=202) (Incontinence Present) | Group II (n=298) (Incontinence Absent) | P value |
|----------------------------------|----------------------------------------|----------------------------------------|---------|
| Age (years)                      | 25.1±3.2                               | 24.9±3.6                               | 0.703   |
| Weight (kg)                      | 57.7±5.0                               | 57.6±5.1                               | 0.912   |
| Height (cm)                      | 151.7±5.0                              | 151.9±5.2                              | 0.815   |
| BMI (kg/m²)                      | 24.9±2.3                               | 25.0±2.1                               | 0.886   |
| Parity                           |                                        |                                        |         |
| Primipara                        | 81                                     | 104                                    | 0.294   |
| Multipara                        | 163                                    | 152                                    |         |
| Past Delivery Mode               |                                        |                                        |         |
| No Past Delivery                 | 91                                     | 86                                     | 0.535   |
| Previous Normal Delivery         | 126                                    | 88                                     |         |

Prevalence and Risk Factors of Urinary Incontinence Among Women Delivering in a Tertiary Care Center of Northern India

Table 2: Risk factors for urinary incontinence.

| Risk Factors     | Odd’s Ratio | (95% Confidence Interval) |
|------------------|-------------|---------------------------|
| Bladder Infection| 3.75        | 1.2-11.2                  |
| Pelvic Pain      | 1.58        | 0.5-4.7                   |
| Chronic Cough    | 4.99        | 1.7-14.5                  |
| Constipation     | 3.23        | 0.7-13.3                  |

Table 3: Frequency of urinary incontinence and treatment seeking behavior.

| Severity of UI | No. of Subjects | Percentage | Treatment Seeking Subjects |
|----------------|-----------------|------------|---------------------------|
| Slight         | 42/202          | 20.7%      | 3 (7.1%)                  |
| Moderate       | 102/202         | 50.4%      | 15 (14.7%)                |
| Severe         | 44/202          | 21.7%      | 8 (18.1%)                 |
| Very Severe    | 14/202          | 6.9%       | 5 (35.4%)                 |

Figure 1: Bar diagram of frequency of urinary incontinence and treatment seeking behavior.

Discussion

Pregnancy is associated with lower urinary tract symptoms and UI is also very troublesome complaints. The most common type of UI is SUI. Subjects who had incontinence in our study was 40.4% which is in the range of the previous study in the literature [20]. In our study SUI was the most common form of incontinence (45.5%) followed by mixed incontinence (34.6%) and thereafter UUI (19.8%). This was also in accordance to previous studies in the literature, which shows that SUI is the most common in pregnancy [21,22]. The fact that SUI is the most common form of UI suggests that pelvic floor exercise can be used for effective prevention of SUI during pregnancy and postpartum period [23]. It has been seen in the previous studies that six weeks pelvic floor muscle exercise programme was able to decrease the severity of symptoms of incontinence with SUI. Despite that nearly half of the pregnant women population was affected by UI, the treatment seeking behavior was only 15.3% of all incontinent women. It was also very interesting to note that only 6.9% of women with very severe UI did seek treatment.

The prevalence of incontinence in primipara was slightly higher than previously reported in literature [21]. In our study 53.4% multipara had incontinence which shows that parity has association with incontinence. In this study sociodemographics pattern did not have any association with UI. Chronic cough and bladder infections had significant relation with UI. After
univariate analysis the Odd’s ratio for UI in subjects with chronic cough and bladder infections was 4-5 times more. Chronic cough itself has direct association with UI [24]. Sudden increase in intra-abdominal pressure leads to exhaustion of pelvic floor muscles. Hence, UI was found to be more common with multiparity, chronic cough and bladder infections in our study.

Limitations

The study population was limited to our tertiary care center. Also, none of the subjects was examined gynaecologically for UI and UI was only inquired verbally which may reduce the accuracy of diagnosis.

Conclusion

A significant number of antenatal women are suffering from UI and it is substantially affecting the quality of life. The women in India are suffering from unawareness about the condition, hence making it difficult to diagnose for physician and further early treatment. Primary prevention of UI is needed by increasing public awareness about pelvic floor muscle exercise during and after pregnancy.
