The syntax of modal graphs is defined in terms of the continuous cut and broken cut following Charles Peirce’s notation in the gamma part of his graphical logic of existential graphs. Graphical calculi for normal modal logics are developed based on a reformulation of the graphical calculus for classical propositional logic. These graphical calculi are of the nature of deep inference. The relationship between graphical calculi and sequent calculi for modal logics is shown by translations between graphs and modal formulas.

1 Introduction

Sequent calculi for normal modal logics can be obtained uniformly from a basic calculus, as has been observed in [23]. The search for generalized cut-free sequent calculi for modal logics has produced display calculus ([3]), hypersequent calculus ([2]), labelled sequent calculus ([10]), hybrid logic calculus ([18]), and deep sequent calculus ([7, 8, 21, 22]). Among these efforts, there are two main approaches. One is the semantic approach; the other largely syntactic. In the semantic approach, labelled calculi exist for a number of complete modal logics. The syntactic approach does not use labels. Each sequent has an obvious corresponding formula. Ordinary sequent calculi and hypersequent calculi for modal logics are syntactic.

Deep inference systems for modal logics, such as deep sequent calculi developed by Brünnler [7, 8] and Stouppa [22], are also largely syntactic. There exists also deep inference for hybrid logic ([19]). The syntax of deep sequents is defined by assuming the negation normal form in classical modal logic and nested sequents. The central idea of deep inference is that deep structures are transformed into appropriate shapes at any position in a derivation that allows the transformation. It has turned out that cut-free sequent calculi can be developed systematically and modularly for normal modal logics.

As often is the case, what is syntactic and what semantic may interestingly overlap, as is the case in the hybrid and two-sided approaches. Also in the graphical and diagrammatic systems the distinction between syntax and semantics is not, and was not originally meant to be by Peirce, razor-sharp, which professes to gain some flexibility when dealing with some more complicated and non-standard systems.

The aim of the present paper is to provide a different kind of deep inference system for normal modal logics. The language is given by Peirce’s alpha and gamma graphs as presented in his theory of existential graphs (see e.g. [13, 14, 17, 24]). Graphs are scribed on the sheet of assertion. Inference rules are formulated as transformation rules from one graph to another graph. In non-modal propositional logic (alpha graphs) and first-order logic (beta graphs), there are basically only two general kinds of transformations: insertions to the graphs and erasures from the graphs. In graphical modal logic, there are two additional kinds of transformations: merges and splits. In a sense also merges and splits are

instances of the operations of insertions and erasures. Thus the fundamental proof rules also in the modal extensions of graphical logic can be classified into two general classes. As usual, these operations are allowed only in certain positions in a graph. It is the notion of a position that is made explicit in graphical logic. This makes such graphical calculi the natural home for deep inference.

Peirce’s theory of existential graphs was generalized into conceptual graphs by Sowa [20] in 1984. Since then conceptual graphs have been widely used within artificial intelligence and cognitive science. Diagrammatic reasoning and their history and philosophy has been studied for many years (see e.g. [1, 15, 16]). As far as modal logics are concerned, van den Berg [4] defines a graphical system for modal logic $K$ which is complete with respect to the Hilbert-style axiomatic system of $K$. Braüner [5] defines a Peircean graphical system for the modal logic $S5$, which is also complete with respect to the Hilbert-style axiomatic system of $S5$. This type of graphical system is also extended by Braüner and Øhrstrøm [6] to modal logics $S4$ and $KD45$. In distinction from the above works, the graphical systems for modal logics presented in this paper are shown to be equivalent to algebraic sequent systems. This means that a range of modal graphical systems can be developed in a systematic and modular fashion.

2 The syntax of modal graphs

We fix a denumerable set of simple propositions $\text{Prop}$ the elements of which are primitive graphs. They occur in a compound graph as basic parts. According to Peirce, the sheet of assertion, or the blank where nothing is scribed on it, is also a primitive graph. It corresponds to tautology $\top$. Henceforth, we denote the blank by $SA$ or omit it altogether when no confusion arises. A primitive graph is a simple proposition or the blank ($SA$).

The modal graphs are defined inductively from primitive graphs using two special notations: the continuous cut $\otimes$ and the broken cut $\oslash$. The continuous cut means negation. The broken cut means logical contingency (non-necessity). The continuous and broken cuts are called primitive cuts uniformly. There are four combinations of cuts:

1. Double continuous cut: $\otimes\otimes$
2. Double broken cut: $\oslash\oslash$
3. Possibility cut: $\otimes\oslash$
4. Necessity cut: $\oslash\otimes$

The compound cuts consist of two cuts, one nested within the other, with nothing between them. The two primitive cuts and the four compound cuts stated above are called cuts uniformly. They are used as single graph operations that form new graphs from the given ones.

**Definition 1.** The set of all modal graphs $\mathcal{G}_M$ is defined inductively by:

$$\mathcal{G}_M \ni G ::= p \mid SA \mid \langle G \rangle \mid \langle G \rangle \mid G_1 G_2$$

where $p \in \text{Prop}$. The graphs $\langle G \rangle$ and $\langle G \rangle$ are read as “the continuous cut of $G$” and “the broken cut of $G$” respectively. The graph $G_1 G_2$ is called the juxtaposition of $G_1$ and $G_2$ on the sheet of assertion.

Henceforth, when we talk about graphs we mean modal graphs. Given two graphs $G$ and $H$, we define shorthand notations $G \otimes H$, $G \oslash H$ and $G \equiv H$ as below:

$$G \otimes H := \langle G \rangle \langle H \rangle; \quad G \oslash H := \langle G \rangle \langle H \rangle; \quad G \equiv H := \langle G \rangle \langle H \rangle \langle H \rangle \langle G \rangle .$$

**Definition 2.** For any graph $G$, the parsing tree of $G$, denoted by $T(G)$, is defined inductively as follows:

1. $T(p)$ is a single root node $p$. 
2. \( T(SA) \) is a single root node \( SA \).

3. \( T(G_1G_2) \) is a root node \( G_1G_2 \) with children nodes \( T(G_1) \) and \( T(G_2) \).

4. \( T(\langle G \rangle) \) is a root node of \( G \) with one child node \( T(G) \).

5. \( T(\langle G \rangle) \) is a root node of \( G \) with one child node \( T(G) \).

A partial graph of a graph \( G \) is a node in \( T(G) \).

For any graph \( G \), the history of a node \( J \) in \( T(G) \), denoted by \( h(J) \), is the unique path from the root to \( J \). The position of the root is always on the sheet of assertion. We say that \( J \) is a positive (negative) node of \( T(G) \) if there is an even (odd) number of cuts in \( h(J) \).

A position is a point on the area of a graph (but not on the boundary of the cut). Given any graph \( G \), a position in \( G \) is positive (negative) if it is enclosed by an even (odd) number of cuts. Graphs are scribbled at positions. No two graphs, or their parts, can be scribbled at the same position.

A graph context is a graph \( G \{ \} \) with a single slot \( \{ \} \), the empty context, which can be filled by other graphs. The notation \( G\{H\} \) stands for the graph obtained from the graph context \( G\{\} \) by filling the slot by \( H \). An occurrence of a graph \( J \) in a graph \( G \) is called positive (negative), notation \( G\{J^+\} \) (\( G\{J^-\} \)), if it is a positive (negative) node in \( T(G) \).

3 The graphical calculi \( K_g \)

Graphical calculi for modal logics are presented by graphical rules. In general, a graphical rule is of the form

\[
\begin{array}{c}
G \\
\hline
H
\end{array}
\]

where \( G \) and \( H \) are graphs. The graph \( G \) is called the premiss, and \( H \) is called the conclusion.

On the sheet of assertion, the syntax of graphs becomes diagrammatic. This means that the syntax is two-dimensional, it has no separate notation for parentheses, and that its well-formed graphs are scribbled in the ambient space which is continuous, compact, open and non-oriented. The following equalities can be thought of as identifying graphs:

\[
(PM) \ G\{H_1H_2\} = G\{H_2H_1\}; \ (AS) \ G\{H_1(H_2H_3)\} = G\{(H_1H_2)H_3\}.
\]

The permutation (PM) says that to distinguish positions of \( H_1 \) and \( H_2 \) in a partial graph \( H_1H_2 \) of \( G \) has no significance. The associativity (AS) says that the order of forming the graphs indicated by the parentheses in these rules is likewise immaterial. After all, these equalities follow from the basic properties of the space and therefore need no separate statement in the system. Likewise, if two graphs, \( G \) and \( H \), are asserted on the sheet of assertion, the the juxtaposition of them, \( GH \), is at once also asserted.

The continuous and broken cuts have different meanings in general. However, the continuous cut of \( SA \) is tantamount to the broken cut of \( SA \) in the sense that it is impossible to falsify a tautology. Hence we assume the following equality:

\[
(Normality) \ \bigcirc = \bigcirc.
\]

This equality says that contradiction is impossible. Its algebraic meaning is the normality condition in modal algebras (Section 5).

**Definition 3.** The graphical calculus \( K_g \) for the minimal normal modal logic \( K \) consists of the following axiom and graphical rules:
1. **Axiom:** \( \text{SA} \) (The Sheet of Assertion)

2. **Alpha rules:**
   - **Deletion:**
     \[
     \frac{G\{H^+\}}{G\{\text{SA}\}} \quad \text{(DEL)}
     \]
     Every positive partial graph \( H \) in a graph \( G \) can be deleted.
   - **Insertion:**
     \[
     \frac{G\{H^−\}}{G\{(JH)^−\}} \quad \text{(INS)}
     \]
     Any graph can be inserted into a negative position in a graph \( G \).
   - **Double cut:**
     \[
     \frac{G\{H\}}{G\{(JH)^−\}} \quad \text{(DC1)} \quad \quad \frac{G\{(JH)^−\}}{G\{H\}} \quad \text{(DC2)}
     \]
     Any partial graph \( H \) of a graph \( G \) can be replaced by the double cut of \( H \), and vice versa.
   - **Iteration/deiteration:**
     \[
     \frac{K\{GH\{J\}\}}{K\{GH\{GJ\}\}} \quad \text{(IT)} \quad \frac{K\{GH\{GJ\}\}}{K\{GH\{J\}\}} \quad \text{(DEIT)}
     \]
     where \( H \{ \} \) is a broken-cut-free graph context, namely, no broken cut occurs in \( H \{ \} \). In a graph \( K\{GH\{J\}\} \), the partial graph \( G \) can be iterated or deiterated at any position in \( H \).

3. **Modal rules:**
   - **(K1)**
     \[
     \frac{J\{(GH)^+\}}{J\{\text{SA}\}}
     \]
     (K1) and (K2) mean that the necessity cut distributes over juxtaposition. We call the rule (K1) splitting and (K2) merging. (DMN) is the rule of downward monotonicity.

   - **(K2)**
     \[
     \frac{J\{G^+\}}{J\{GH\}}
     \]
     \[
     \frac{J\{(G^+H)^+\}}{J\{H^+:G^+:\}}
     \]
   - **(DMN)**
     \[
     \frac{p \{q\} \succ p \{\text{q}\}}{p \{\text{q}\} \succ p \{pq\}} \quad \text{(I)} \quad \frac{p \{\text{q}\} \succ p \{\text{q}\}}{p \{\text{q}\} \succ p \{\text{q}\}} \quad \text{(II)}
     \]
     The premises of (I) and (II) are valid, but their conclusions are not valid in the algebraic semantics for \( K_8 \) (Section 5). (I) is a counterexample to the validity of iteration into broken cut, and (II) is a counterexample to the validity of deiteration from a broken cut.

**Remark 1.** The restriction on the context \( H \{ \} \) in (IT) and (DEIT) rules is significant. Iteration/deiteration in a modal context may lead to invalid inferences. For example, consider the following two inferences where the rules (IT) and (DEIT) are applied into the broken cut:

   - **(I)**
     \[
     \frac{p \{q\} \succ p \{\text{q}\}}{p \{\text{q}\} \succ p \{pq\}} \quad \text{(I)}
     \]
     - **(II)**
       \[
       \frac{p \{\text{q}\} \succ p \{\text{q}\}}{p \{\text{q}\} \succ p \{\text{q}\}} \quad \text{(II)}
       \]

The graphs \( G \succ \text{SA} \) and \( G \succ G \) are derivable in \( K_8 \).
Proof. We have the following proofs:

\[
\begin{array}{c}
\frac{SA}{G} \quad (DC1) \\
\frac{SA}{G \circ G} \quad (INS) \\
\end{array}
\]

This completes the proof.

\[
\qed
\]

**Proposition 1.** The following rules are admissible in \( K_s \):

1. De Morgan rules:

\[
\frac{GH}{G \circ H} \quad (DM1) \quad \frac{G \circ H}{GH} \quad (DM2)
\]

2. Contraposition and transitivity rules:

\[
\frac{G \supset H}{H \supset G} \quad (CP) \quad \frac{G \supset H \supset J}{G \supset J} \quad (TR)
\]

3. Prefixing and Modus Ponens:

\[
\frac{G}{H \supset G} \quad (PF) \quad \frac{G \supset H}{H} \quad (MP)
\]

4. Lattice rules:

\[
\begin{array}{c}
\frac{G_1 \supset H}{G_1 G_2 \supset H} \quad (&L) \\
\frac{G \supset H \supset J}{G \supset H J} \quad (&R) \\
\frac{G \supset J \supset H \supset J}{G \circ H \supset J} \quad (\oplus L) \\
\frac{G \supset H_i}{G \supset H_1 \oplus H_2} \quad (\oplus L) \\
\frac{G \supset H \supset J}{H \supset G \supset J} \quad (NL) \\
\frac{GH \supset J}{H \supset (G \supset J)} \quad (NR)
\end{array}
\]

5. Residuation rules:

\[
\begin{array}{c}
\frac{GH \supset J}{G \supset (H \supset J)} \quad (RG1) \\
\frac{G \supset (H \supset J)}{GH \supset J} \quad (RG2)
\end{array}
\]

6. Distributivity:

\[
\begin{array}{c}
\frac{G (H \circ J)}{GH \circ J} \quad (D1) \\
\frac{GH \circ J}{G \circ (H \circ J)} \quad (D2)
\end{array}
\]

7. Upward monotonicity:

\[
\begin{array}{c}
\frac{G \supset H}{G \supset (H \supset H)} \quad (UMN) \\
\frac{G \supset H}{G \supset (G \supset H)} \quad (UMP) \\
\frac{G \supset H}{G \supset (H \supset H)} \quad (UMDB)
\end{array}
\]

8. Replacement of equivalents:

\[
\frac{G \equiv H}{J \{G\} \equiv J \{H\}} \quad (RE)
\]

9. Necessitation rule:

\[
\frac{G}{\langle G \rangle} \quad (Nec)
\]
Graphical Sequent Calculi for Modal Logics

Proof. For (DM1) and (DM2), we have the following simple proofs that only use the double-cut rules:

\[
\frac{GH}{\frac{G}{\frac{\frac{\frac{G}{H}}{}}{}}}{(DC1)} \quad \frac{\frac{\frac{G}{H}}{}}{\frac{G}{\frac{\frac{\frac{G}{H}}{}}{}}}{(DC1)} \quad \frac{\frac{G}{H}}{\frac{\frac{G}{\frac{\frac{G}{H}}{}}{}}}{(DC2)} \quad \frac{\frac{G}{H}}{\frac{\frac{\frac{G}{H}}{}}{}}}{(DC2)}
\]

(TR) is shown as follows:

\[
\frac{G}{\frac{\frac{J}{H}}{}}{\text{(IT)}} \quad \frac{\frac{J}{H}}{\frac{\frac{\frac{J}{H}}{}}{}}{\text{(IT)}} \quad \frac{\frac{J}{H}}{\frac{\frac{\frac{J}{H}}{}}{}}{\text{(IT)}} \quad \frac{\frac{J}{H}}{\frac{\frac{\frac{J}{H}}{}}{}}{\text{(IT)}}
\]

For (D1) and (D2), we have the following proofs (9):

\[
\frac{\frac{G}{\frac{\frac{H}{J}}{}}}{\frac{G}{\frac{\frac{\frac{H}{GJ}}{}}{}}}{\text{(IT)}} \quad \frac{\frac{G}{\frac{\frac{H}{GJ}}{}}}{\frac{G}{\frac{\frac{\frac{G}{H}}{}}{}}}{\text{(IT)}} \quad \frac{\frac{G}{\frac{\frac{H}{GJ}}{}}}{\frac{G}{\frac{\frac{\frac{G}{H}}{}}{}}}{\text{(IT)}} \quad \frac{\frac{G}{\frac{\frac{H}{GJ}}{}}}{\frac{G}{\frac{\frac{\frac{G}{H}}{}}{}}}{\text{(IT)}}
\]

The rule (RE) is shown by induction on the construction of \( J \{ \} \) as follows. Assume \( G \equiv H \). If \( J \{ \} = \{ \} \), the conclusion is the same as the premiss. Suppose \( J \{ \} = J' \{ \} \). By induction hypothesis, we have \( J' \{ G \} \equiv J' \{ H \} \). Then it is easy to show \( J' \{ G \} \equiv J' \{ H \} \). Assume \( J \{ \} = J_1 J_2 \{ \} \). By induction hypothesis, we have \( J_2 \{ G \} \equiv J_2 \{ H \} \). Then it is easy to show \( J_1 J_2 \{ G \} \equiv J_1 J_2 \{ H \} \).

The rule (UMN) is obtained from (DMN) by the rule of contraposition (CP). (Nec) is shown by (PF), (UMN) and (TR). The other rules are easily shown. \( \square \)

Theorem 1 (Cut-elimination). The following cut-elimination rule

\[
\frac{J \{ G \} \{ J \} \{ G \}}{J \{ SA \}} {\text{(Cut-E)}}
\]

is admissible in \( K_\beta \).

Proof. Clearly \( G \{ G \} \equiv SA \) is provable in \( K_\beta \). By (RE), we have \( J \{ G \} \{ J \} \{ G \} \equiv J \{ SA \} \). Assume \( \vdash_{K_\beta} J \{ G \} \{ J \} \{ G \} \). By (TR), we have \( \vdash_{K_\beta} J \{ SA \} \). \( \square \)

4 Extensions

Extensions of \( K_\beta \) can be obtained by adding some characteristic rules. The formulation of these characteristic rules will make use of the cuts, including the six cuts (two primitive and four combined ones)
we introduced in Section 2. We say that the occurrence of a cut in a graph is positive (negative) if it is enclosed evenly (oddly) by primitive cuts (continuous or broken cuts).

A normal modal graphical calculus is an extension of $K_g$ with a set of graphical rules. Given a set of rules $\Sigma = \{R_i | i \in I\}$, the notation $K\Sigma$ denotes the calculus generated by rules in $\Sigma$. Let us have the following rules of transformation as the basic rules for various systems of graphical modal logic:

(D) Any positive necessity cut can be transformed into a possibility cut. Any negative possibility cut can be transformed into a necessity cut.

\[
\frac{J\{G^+\}}{J\{G^-\}} (D^+) \quad \frac{J\{G^+\}}{J\{G^-\}} (D^-)
\]

(T) Any positive continuous cut can be transformed into a broken cut. Any negative broken cut can be transformed into a continuous cut.

\[
\frac{J\{G^+\}}{J\{G^+\}} (T^+) \quad \frac{J\{G^-\}}{J\{G^-\}} (T^-)
\]

(4) Any positive necessity cut can be doubled. Any negative possibility cut can be doubled.

\[
\frac{J\{G^+\}}{J\{G^+\}} (4^+) \quad \frac{J\{G^-\}}{J\{G^-\}} (4^-)
\]

(B) Any positive double broken cut can be deleted. Any double broken cut can be inserted into a negative position.

\[
\frac{J\{G^+\}}{J\{G^+\}} (B^+) \quad \frac{J\{G^-\}}{J\{G^-\}} (B^-)
\]

(5) Any positive double broken cut can be transformed into a necessity cut. Any negative possibility cut can be transformed into a double broken cut.

\[
\frac{J\{G^+\}}{J\{G^+\}} (5^+) \quad \frac{J\{G^-\}}{J\{G^-\}} (5^-)
\]

**Definition 4.** Let $(X) = \{(X^+), (X^-)\}$ for $X \in \{D,T,4,B,5\}$. We define the following graphical calculi:

- $KD_g = K_g(D)$
- $KB_g = K_g(B)$
- $K4_g = K_g(4)$
- $K5_g = K_g(5)$
- $KT_g = K_g(T)$
- $KDB_g = KD_g(B)$
- $KB4_g = KB_g(4)$
- $KD4_g = KD_g(4)$
- $KD5_g = KD_g(5)$
- $KB5_g = KB_g(5)$
- $K45_g = K4_g(5)$
- $KTB_g = KT_g(B)$
- $S4_g = KT_g(4)$
- $S5_g = KT_g(5)$

Let $S$ be any one of the systems in Definition 4. Let $S^+$ and $S^-$ be the systems obtained from $S$ by dropping the negative and positive rules respectively.

**Theorem 2.** $S^+ = S = S^-$. 

Proof. Consider $\mathbf{KT}^+ = \mathbf{K}_p(T^+)$. It suffices to show that $(T^-)$ is provable in $\mathbf{KT}^+$. Assume that $J\{\langle \mathbf{G}^- \rangle \}$ is provable in $\mathbf{KT}^+$. There are two cases:

Case 1. $J\{\langle \mathbf{G}^- \rangle \} = J'(\langle \mathbf{H} \mathbf{G} \rangle)$. First, it is easy to prove $(\mathbf{G}) \supset (\mathbf{G})$ in $\mathbf{KT}^+$. Then we have the following proof:

\[
\frac{(\mathbf{G}) \supset (\mathbf{G})}{(H \mathbf{G}) \supset (\mathbf{G})} \quad \text{(\&L)} \quad \frac{(H \mathbf{G}) \supset (\mathbf{G})}{(H \mathbf{G}) \supset (\mathbf{G})} \quad \text{(TR)} \quad \frac{(H \mathbf{G}) \supset (\mathbf{G})}{(H \mathbf{G}) \supset (\mathbf{H} \mathbf{G})} \quad \text{(\&L)} \quad \frac{(H \mathbf{G}) \supset (\mathbf{H} \mathbf{G})}{(H \mathbf{G}) \supset (\mathbf{H} \mathbf{G})} \quad \text{(\&R)} \quad \frac{(H \mathbf{G}) \supset (\mathbf{H} \mathbf{G})}{(H \mathbf{G}) \supset (\mathbf{H} \mathbf{G})} \quad \text{(DMN)} \quad \frac{(H \mathbf{G}) \supset (\mathbf{H} \mathbf{G})}{(H \mathbf{G}) \supset (\mathbf{H} \mathbf{G})} \quad \text{(Alpha rules)}
\]

Case 2. $J\{\langle \mathbf{G}^- \rangle \} = J'(\langle \mathbf{H} \mathbf{G} \rangle)$. We have the following proof:

\[
\frac{(\mathbf{G}) \supset (\mathbf{G})}{(H \mathbf{G}) \supset (\mathbf{G})} \quad \text{(Alpha rules)} \quad \frac{(H \mathbf{G}) \supset (\mathbf{G})}{(H \mathbf{G}) \supset (\mathbf{G})} \quad \text{(CP)} \quad \frac{(H \mathbf{G}) \supset (\mathbf{G})}{(H \mathbf{G}) \supset (\mathbf{G})} \quad \text{(Alpha rules)}
\]

Hence $(T^-)$ is provable in $\mathbf{KT}^+$. The remaining cases of $S$ are shown similarly. □

5 Graphical and sequent calculi

The set of all modal formulas $\mathcal{L}_M$ is defined by the following inductive rule:

\[\mathcal{L}_M \ni \alpha ::= p \mid \top \mid \neg \alpha \mid (\alpha \land \beta) \mid \Box \alpha,\]

where $p \in \mathbf{Prop}$. Other propositional connectives $\bot, \lor, \to$ and $\iff$ are defined as usual. The dual operator of $\lozenge$ is defined as $\lozenge \alpha := \neg \Box \neg \alpha$. A basic sequent is an expression of the form $\alpha \vdash \beta$.

**Definition 5.** The basic sequent calculus $\mathbf{SK}$ consists of the following axioms and rules:

1. **Axioms:**

   (Id) $\alpha \vdash \alpha$,  
   (T) $\alpha \vdash \top$,  
   (D) $\alpha \land (\beta \lor \gamma) \vdash (\alpha \land \beta) \lor (\alpha \land \gamma)$,  
   (Em) $\top \vdash \alpha \land \neg \alpha$,  
   (Gen) $\top \vdash \Box \top$,  
   (\Box \land) $\Box \alpha \land \Box \beta \vdash \Box (\alpha \land \beta)$.

2. **Rules for propositional connectives:**

   \[
   \frac{-\alpha \vdash \beta}{\beta \vdash \alpha} \quad \text{(-L)} \quad \frac{\alpha \vdash \neg \beta}{\beta \vdash \alpha} \quad \text{(-R)} \quad \frac{\alpha \vdash \beta}{\alpha \vdash \gamma} \quad \text{(Tr)}
   \]

   \[
   \frac{\alpha \land \beta \vdash \alpha_i \land \alpha_2 \vdash \beta}{\alpha \land \beta \vdash \alpha_i \land \alpha_2 \vdash \beta} \quad \text{(^L}(i = 1, 2) \quad \frac{\beta \vdash \alpha_i \land \alpha_2 \vdash \beta}{\beta \vdash \alpha_i \land \alpha_2 \vdash \beta} \quad \text{(^R)}
   \]

3. **Modal rule:**

   \[
   \frac{\alpha \vdash \beta}{\Box \alpha \vdash \Box \beta} \quad \text{(^D)}
   \]
By the standard Lindenbaum–Tarski construction, one can easily obtain the following completeness result:

**Theorem 3.** A sequent is derivable in $\text{SK}$ iff it is valid in all modal algebras.

We shall present the translations between the modal language $\mathcal{L}_M$ and the graphical language $\mathcal{G}_M$, and then prove the connections between the graphical calculus $\text{K}_g$ and the sequent calculus $\text{SK}$.

**Definition 6.** The translation $\pi: \mathcal{G}_M \rightarrow \mathcal{L}_M$ is defined inductively by

$$
\pi(p) = p; \quad \pi(\top) = \top; \quad \pi(\neg G) = \neg \pi(G);
$$

$$
\pi(\Diamond G) = \Diamond \neg \pi(G); \quad \pi(G_1 G_2) = \pi(G_1) \land \pi(G_2).
$$

The translation $\sigma: \mathcal{L}_M \rightarrow \mathcal{G}_M$ is defined inductively by

$$
\sigma(p) = p; \quad \sigma(\top) = \top; \quad \sigma(\neg \varphi) = \sigma(\varphi),
$$

$$
\sigma(\Box \varphi) = \Box \sigma(\varphi); \quad \sigma(\varphi_1 \land \varphi_2) = \sigma(\varphi_1) \land \sigma(\varphi_2).
$$

The two translations $\pi$ and $\sigma$ are related to each other. The relationship can be presented by the following result:

**Proposition 2.** There are functions $\delta: \mathcal{L}_M \rightarrow \mathcal{L}_M$ and $\rho: \mathcal{G}_M \rightarrow \mathcal{G}_M$ such that the following diagrams commute:

\[
\begin{array}{ccc}
\mathcal{L}_M & \xrightarrow{\sigma} & \mathcal{G}_M \\
\delta & & \pi \\
\mathcal{G}_M & \xrightarrow{\pi} & \mathcal{L}_M \\
\mathcal{L}_M & \xrightarrow{\rho} & \mathcal{G}_M \\
\end{array}
\]

i.e., $\pi \circ \sigma = \delta$ and $\sigma \circ \pi = \rho$.

**Proof.** As we are using them later on, let us first define the two (redundant) functions $\delta$ and $\rho$ as follows. Define the function $\delta$ inductively by: $\delta(p) = p$, $\delta(\top) = \top$, $\delta(\neg \varphi_1 \land \varphi_2) = \delta(\varphi_1) \land \delta(\varphi_2)$, and $\delta(\Box \varphi) = \neg \Diamond \neg \varphi$. By induction on the construction of a modal formula $\varphi$ one can easily show $\sigma(\pi(\varphi)) = \delta(\varphi)$. Hence (I) commutes. Define the function $\rho$ inductively as follows:

$$
\rho(p) = p, \quad \rho(\top) = \top, \quad \rho(G_1 G_2) = G_1 G_2,
$$

$$
\rho(\Diamond G) = \Diamond G, \quad \rho(\Box G) = \Box G.
$$

By induction on the construction of a graph $G$ one can easily show that $\sigma(\pi(G)) = \rho(G)$. Hence (II) commutes.

A formula context is a formula structure $\alpha \{ \}$ with a single slot $\{ \}$ which can be filled with a formula. Let $\alpha \{ \beta \}$ be the formula obtained from $\alpha \{ \}$ by filling the slot by $\beta$. The notation $\alpha \{ \beta^+ \}$ stands for that $\beta$ is positive in $\alpha$, i.e., $\beta$ is in the scope of an even number of negation symbols. Similarly we use the notation $\alpha \{ \beta^- \}$.

**Lemma 2.** The following hold in $\text{SK}$:
Proof. By induction on the construction of \( \alpha \). We sketch the proof of (1) and (2) by simultaneous induction. The case \( \alpha = \{ \} \) is obvious. Suppose \( \alpha = \{ \beta \} := -\alpha' \beta \) and \( \beta \vdash \top \gamma \). There are two cases:

Case 1. \( -\alpha' \beta^+ \). Then \( \alpha' \beta^- \). By induction hypothesis, we have \( \alpha' \beta \vdash \top \alpha' \beta \). Then \( -\alpha' \beta \vdash \top -\alpha' \beta \).

Case 2. \( -\alpha' \beta^- \). Then \( \alpha' \beta^+ \). By induction hypothesis, we have \( \alpha' \beta \vdash \top \alpha' \gamma \). Then \( -\alpha' \gamma \vdash \top -\alpha' \beta \).

The case \( \alpha = \{ \alpha_1 \} \wedge \alpha_2 \) or \( \alpha = \{ \alpha_1 \} \wedge \alpha_2 \) is obvious. Suppose \( \alpha = \{ \} = -\alpha' \} \) and \( \beta \vdash \top \gamma \). Assume \( \square \alpha' \beta^+ \). Then by induction hypothesis we have \( \alpha' \beta \vdash \top \alpha' \gamma \). Then by (□) we have \( \square \alpha' \beta^- \). The case for \( \square \alpha' \beta^- \) is similar.

Lemma 3. For any graph \( G \), if \( \vdash_{K_n} G \), then \( \top \vdash_{SK} \pi(G) \).

Proof. Assume \( \vdash_{K_n} G \). Let \( G_0, \ldots, G_n = G \) be a proof of \( G \). We show \( \top \vdash_{SK} \pi(G) \) by induction on \( i \leq n \). If \( G_i \) is \( SA \), clearly we have \( \top \vdash_{SK} \pi(G_i) \). Assume that \( G_i \) is obtained from \( G' \) by a rule \((R)\). If \( (R) \) is an alpha rule, it is easy to get the conclusion by induction hypothesis and Lemma 2. Suppose that \( (R) \) is a modal rule.

(1). \((R) = (K1) \) or \( (K2) \). Let \( G_i = J\{ (H \cap K) \} \) and \( G' = J\{ (H \cup K) \} \). By induction hypothesis, we have \( \top \vdash_{SK} \pi(J\{ \pi((H \cap K)) \}) \). By induction hypothesis, we get \( \top \vdash_{SK} \pi(G_i) \).

(2). \((R) = (DMN) \). Let \( G_i = J\{ (H \supset K) \} \) and \( G' = J\{ (H \supset K) \} \). By induction hypothesis, we have \( \top \vdash_{SK} \pi(J\{ \pi((H \supset K)) \}) \). By induction hypothesis, we get \( \top \vdash_{SK} \pi(G_i) \).

Lemma 4. For any formula \( \alpha \), if \( \top \vdash_{SK} \alpha \), then \( \vdash_{K_n} \sigma(\alpha) \).

Proof. By induction on the derivation of \( \top \vdash \alpha \). The proof is omitted.

Lemma 5. For any graph \( G \), \( \vdash_{K_n} G \) iff \( \vdash_{K_n} \rho(G) \).

Proof. By induction on the proof of \( G \) in \( K_n \). The proof is omitted.

Theorem 4. For any graph \( G \), \( \vdash_{K_n} G \) iff \( \top \vdash_{SK} \pi(G) \).

Proof. The ‘only if’ part is obtained by Lemma 3. Assume \( \top \vdash_{SK} \pi(G) \). By Lemma 4, we have \( \vdash_{K_n} \sigma \circ \pi(G) \). By Proposition 2, \( \vdash_{K_n} \rho(G) \). By Lemma 5, \( \vdash_{K_n} G \).

Definition 7. A modal algebra is an algebra \( A = (A, \wedge, -1, -1) \) where \( (A, \wedge, -1) \) is a Boolean algebra, and \( -1 \) is a unary operator on \( A \) satisfying the conditions:

1. Additivity: for all \( a, b \in A \), \( -1(a \wedge b) = -1a \wedge -1b \);
2. Normality: \( -11 = 1 \).
Any formula \( \alpha \) is interpreted as a function \( \alpha^A \) in a modal algebra \( A \). A sequent \( \alpha \vdash \beta \) is valid in \( A \) if \( \alpha^A \leq \beta^A \) whatever elements of \( A \) are assigned to variables in \( \alpha \) or \( \beta \). By the standard Lindenbaum–Tarski construction, one can show the completeness of \( \mathbf{SK} \) with respect to the class of all modal algebras, i.e., \( \alpha \vdash_{\mathbf{SK}} \beta \) if and only if \( \alpha \vdash \beta \) is valid in all modal algebras (Theorem [3]).

A graph \( G \) is interpreted as the function \( G^A = \pi(G)^A \). A graph \( G \) is valid in a modal algebra \( A \) if \( \top \vdash \pi(G) \) is valid in \( A \). Then one can obtain the following completeness result:

**Theorem 5.** A graph \( G \) is provable in \( K_g \) iff it is valid in all modal algebras.

**Proof.** The soundness is shown by induction on the proof of \( G \). For completeness, assume \( \top \vdash_{K_g} G \). By Theorem [4] we have \( \top \vdash_{\mathbf{SK}} \pi(G) \). By the completeness of \( \mathbf{SK} \), there is a modal algebra \( A \) with \( 1 \not\leq \pi(G)^A \). Then \( G \) is not valid in \( A \).

For any set of modal formulas \( \Sigma \), let \( \Sigma^\leq = \{ \top \vdash \alpha \mid \alpha \in \Sigma \} \). Then we have the basic sequent calculus \( \mathbf{SK}^\Sigma^+ \) which is obtained from \( \mathbf{SK} \) by adding all sequents in \( \Sigma^\leq \) as axioms. Let \( \text{Alg}(\Sigma) \) be the class of all modal algebras that validate all sequents in \( \Sigma^\leq \). Then the sequent system \( \mathbf{SK}^\Sigma^+ \), if consistent, is sound and complete with respect to \( \text{Alg}(\Sigma) \).

For any set of modal formulas \( \Sigma \), consider the set of graphical rules \( \Sigma^g = \{ \top \vdash \sigma(\alpha) \mid \alpha \in \Sigma \} \). Let \( K_g, \Sigma^g \) be the graphical calculus obtained from \( K_g \) by adding all rules in \( \Sigma^g \).

For \( \Sigma \subseteq \{ D, T, 4, B, 5 \} \), where \( D = \Diamond \top, \ T = \Box \alpha \rightarrow \alpha, \ 4 = \Box \alpha \rightarrow \Box \Box \alpha, \ B = \alpha \rightarrow \Box \Diamond \alpha \) and \( 5 = \Diamond \alpha \rightarrow \Box \Diamond \alpha \), one can show that the calculus \( K_g, \Sigma^g \) is equivalent to \( \mathbf{SK}^\Sigma^+ \) by the translation \( \pi \). The proof is similar to Theorem [4] Moreover, the graphical calculi \( K_g, \Sigma^g \) are sound and complete with respect to \( \text{Alg}(\Sigma) \).

## 6 Conclusion

Graphical calculi for modal logics developed in the present paper are systematic and modular. They are modal graphical versions of Gentzen-style sequent systems. They follow closely Peirce’s original presentation in another sense as well: the rules arise systematically from Peirce’s presentation of broken-cut gamma graphs and their rules (R 467, 478). Only (DMN), (B) and (5) are new. In the basic system \( K_g \), identifying a vacant broken-cut with a vacant continuous cut dispenses with necessitation as a primitive rule. Moreover, the basic rules are perfectly symmetrical. Thanks to the diagrammatic syntax, graphs need not assume negation normal form. Thus there are good prospects for developing deep inference proof systems for non-normal and intuitionistic modal logics in a similar fashion. The notions of position in the areas of cuts and the polarity of positions likewise result immediately from the diagrammatic language that these systems are built upon. Thus diagrammatic syntax can be considered

---

1We find Peirce’s own remarks suggesting that he was not keen to have (B) or (5) as rules in his modal gamma systems: “There is not much utility in a double broken cut. Yet it may be worth notice that \( \langle \overline{g} \rangle \) and \( g \) can neither of the be inferred from the other. The outer of the two broken cuts is not only relative to a state of information but to a state of reflection. The graph \( \langle \overline{g} \rangle \) asserts that it is possible that the truth of the graph \( g \) is necessary. It is only because I have not sufficiently reflected upon the subject that I can have any doubt of whether it is so or not” (R 467, 1903). The rule (5) uses a principle that is contrary to Peirce’s own rules of \( (T^+) \) and \( (T^-) \). Since Peirce’s preferred interpretation of the broken cut modality was an epistemic one, he would not have recommended (5) as a good rule for knowledge. The previous quotation indeed continues as follows: “It becomes evident, in this way, that a modal proposition is a simple assertion not about the universe of things but about the universe of facts that one is in a state of information sufficient to know. The graph \( \langle \overline{g} \rangle \) without any selective, merely asserts that there is a possible state of information in which the knower is not in a condition to know that the graph \( g \) is true, while \( \langle \overline{g} \rangle \) asserts that there is no such possible state of information”. 
to be an advantage when compared to languages and notations that are used in other deep inference systems. Labels are likewise not needed.

As to some other future work, the specific sense of the cut-elimination process suggests that there are interesting decision procedures that we can get from proof searches in the proposed calculi. The desirable property is the subformula property, as well as a syntactic calculation of interpolants, among others.
