Resveratrol Improves Oxidative Stress and Protects Against Diabetic Nephropathy Through Normalization of Mn-SOD Dysfunction in AMPK/SIRT1-Independent Pathway

Munehiro Kitada, Shinji Kume, Noriko Imaizumi, and Daisuke Koya

OBJECTIVE—Despite the beneficial effects of resveratrol (RSV) on cardiovascular disease and life span, its effects on type 2 diabetes remain unknown. This study examined the renoprotective effects of RSV in db/db mice, a model of type 2 diabetes.

RESEARCH DESIGN AND METHODS—db/db mice were treated with RSV (0.3% mixed in chow) for 8 weeks. We measured urinary albumin excretion (UAE), histological changes (including mesangial expansion, fibronectin accumulation, and macrophage infiltration), oxidative stress markers (urinary excretion and mitochondrial content of 8-hydroxy-2’-deoxyguanosine [8-OHdG], nitrotyrosine expression), and manganese-superoxide dismutase (Mn-SOD) activity together with its tyrosine-nitrated modification and mitochondrial biogenesis in the kidney. Blood glucose, glycated hemoglobin, and plasma lipid profiles were also measured. The phosphorylation of 5’-AMP-activated kinase (AMPK) and expression of silent information regulator 1 (SIRT1) in the kidney were assessed by immunoblotting.

RESULTS—RSV significantly reduced UAE and attenuated renal pathological changes in db/db mice. Mitochondrial oxidative stress and biogenesis were enhanced in db/db mice; however, Mn-SOD activity was reduced through increased tyrosine-nitrated modification. RSV ameliorated such alterations and partially improved blood glucose, glycated hemoglobin, and abnormal lipid profile in db/db mice. Activation of AMPK was decreased in the kidney of db/db mice compared with db/m mice. RSV neither modified AMPK activation nor SIRT1 expression in the kidney.

CONCLUSIONS—RSV ameliorates renal injury and enhanced mitochondrial biogenesis with Mn-SOD dysfunction in the kidney of db/db mice, through improvement of oxidative stress via normalization of Mn-SOD function and glucose-lipid metabolism. RSV has antioxidative activities via AMPK/SIRT1-independent pathway. Diabetes 60:634–643, 2011

Resveratrol (RSV; 3,5,4’-trihydroxystilbene) is reported to be beneficial in cardiovascular diseases (1) and renal diseases (2–4), including ischemic/reperfusion injury (5). The beneficial effects are thought to be due to its antioxidative properties because it is known as a robust scavenger of superoxide (O2•−), hydroxyl radicals, and peroxynitrite (6,7). Oxidative stress has been implicated in the pathogenesis of diabetic vascular complications, including nephropathy (8). The mitochondria are recognized as one of the major sources of reactive oxygen species (ROS) in diabetes (9), and they can also be damaged by ROS. Manganese-superoxide dismutase (Mn-SOD), which is an important antioxidative enzyme and mainly regulates ROS metabolism in the mitochondria, is one of the mitochondrial targets of ROS such as peroxynitrite, and thus its activity might become reduced with ROS exposure (10). Therefore, conditions that lead to Mn-SOD dysfunction could increase ROS production and hence induce tissue damage associated with diabetic nephropathy. However, it remains unclear whether mitochondrial oxidative stress associated with Mn-SOD dysfunction contributes to diabetes-induced renal injury, and whether RSV has any beneficial effects on mitochondrial status including oxidative stress and biogenesis in the kidney of type 2 diabetes.

Reduced mitochondrial biogenesis and function are found in insulin-resistant metabolic tissues including skeletal muscle, liver, and fat in association with the pathogenesis of type 2 diabetes (11). In addition to the scavenging of ROS, RSV enhances mitochondrial biogenesis through the 5’-AMP-activated kinase (AMPK)/silent information regulator 1 (SIRT1) pathway in the muscle and liver, resulting in life span extension or improvement of high-fat diet–induced metabolic impairment such as obesity and insulin resistance (12–14). On the other hand, mitochondrial biogenesis can be induced in tissues not only by increased energy demands due to cold, exercise, and metabolic changes such as those induced by caloric restriction (15), but also by damage to mitochondria caused by oxidative stress (16–18) and hereditary disorders (19). Oxidative stress-induced mitochondrial biogenesis has also been reported in various tissues and cells (16–18), including the myocardium of an animal model of type 1 diabetes (20). There is little information on whether mitochondrial status including mitochondrial biogenesis is changed in the kidney of type 2 diabetes, and if so, how it is regulated and whether it is related to the pathogenesis of diabetic nephropathy.

Thus, the aim of this study was to investigate the potential effects of RSV on mitochondrial oxidative stress associated with Mn-SOD dysfunction and mitochondrial biogenesis in the kidney of db/db mice. The results of the current study indicate that the enhanced mitochondrial biogenesis with Mn-SOD dysfunction induced by tyrosine nitration was observed in the diabetic kidney. Treatment with RSV resulted in the amelioration of these functional
TABLE 1

Effects of RSV treatment on body weight, kidney weight, blood pressure, blood glucose, glycated hemoglobin, and lipid profiles in the four groups of mice. Glycated hemoglobin was measured using an ADAMS-HAS106 analyzer (ARKRAY, Kyoto, Japan). Serum insulin levels and urinary albumin excretion were measured with ELISA kits. Triglycerides, total cholesterol, and nonesterified fatty acid (NEFA) were measured using an L-type triglyceride H kit, cholesterol E-test kit, and NEFA C-test kit, respectively.

and histological abnormalities and mitochondrial biogenesis in the diabetic kidney, possibly by the attenuation of oxidative stress through scavenging of ROS, normalization of Mn-SOD dysfunction in an AMPK/SIRT1-independent mechanism, and partial improvement of glucose-lipid metabolism.

RESEARCH DESIGN AND METHODS

Materials and antibodies. Details of the materials and antibodies used in the current study are available in the Supplementary Data.

Animals. Male db/db mice and age-matched db/m mice were purchased from Clea Japan (Tokyo, Japan). At 9 weeks of age, mice were divided into four groups: db/m, db/db mice, db/m mice treated with RSV, and db/db mice treated with RSV. RSV was mixed (0.3%) with chow and administered orally. Body weight, blood glucose level, food consumption, and blood pressure were measured every 2 weeks in all animals. The blood pressure of conscious mice was measured at steady state by a programmable tail-cuff sphygmomanometer (BP98-A; Softron, Tokyo, Japan). At 17 weeks of age, individual mice were placed in metabolic cages for 24-h urine collection. The urine samples were stored at −80°C until analysis. Mice were anesthetized by intraperitoneal injection of pentobarbital sodium, and then the right kidneys were removed and stored at −80°C for experiments as described below. After collection of blood samples from the left cardiac ventricle, the left kidney was perfused with ice-cold phosphate-buffered saline (PBS) and 10% neutral buffered formalin and then removed. The Research Center for Animal Life Science of Kanazawa Medical University approved all experiments.

Morphological analysis and immunohistochemistry. To assess the mesangial expansion, thirty glomeruli, cut at the vascular pole, randomly selected from each mouse were measured the periodic acid/Schiff (PAS)-positive material containing 100 µM protein for immunoprecipitation with rabbit polyclonal (1:1000) or rabbit polyclonal anti-AMPK (Thr172) antibody, anti-AMPK α, anti-AMPK β, and anti-AMPK γ antibodies. Cellular cAMP accumulation in renal isolated mitochondria.

M. KITADA AND ASSOCIATES
polybrene (1 g/mL). The infected cells were selected by treatment with puromycin (2.5 μg/mL) for several days as described previously (28).

**Infection of adenoviral dominant-negative-AMPK.** Adenoviruses containing green fluorescent protein (Ad-GFP) or dominant-negative AMPK (DN-AMPK) were added to subconfluent mProx at a concentration of 50 multiplicity of infection for 1 h at 37°C in serum-free Dulbecco’s modified Eagle’s medium (29).

**Detection of ROS in mProx.** To determine the effect of RSV on oxidative stress in mProx, cells were incubated with RSV (10 μmol/L) for 180 min at 37°C before exposure to H₂O₂ (10 μmol/L). After incubation, the levels of intracellular ROS were measured with the fluoroprobe 2,7-dichlorodihydrofluorescein diacetate. The intracellular ROS was evaluated as the fluorescence intensity (an excitation wavelength 488 nm, an emission wavelength 525 nm) of dichlorofluorescein by Infinite M200 microplate reader (Tecan Japan Co., Kanagawa, Japan). The results of intracellular ROS are expressed in arbitrary units.

**mtDNA content.** Well-conserved nuclear and other mitochondrial genes were selected to quantify mtDNA copy number per nuclear genome. Cytochrome c oxidase subunit 2 was used as a marker for mtDNA and uncoupling protein 2 for nuclear DNA. Renal DNA was extracted from frozen kidney tissues of all animals using the DNeasy tissue kit. Total DNA concentration was determined using a PicoGreen DNA quantitation kit. Specific mouse primer sequences are provided in the Supplementary Table 1. mtDNA per nuclear genome was calculated as the ratio of cytochrome c oxidase subunit 2 DNA to uncoupling protein 2 DNA (30) and expressed as the fold increase relative to that found in db/m mice.

**Citrate synthase activity.** Citrate synthase activity in the kidney was determined using the citrate synthase activity measurement kit, according to the manufacturer’s instructions.

**Electron microscopy.** The mitochondria in proximal tubular cells were observed by electron microscopy as previously described (23). Mitochondrial area and number were estimated in 15–18 micrographs, which were taken for renal proximal tubular cells of three animals of each group (20). The mitochondrial area was measured using the ImageJ software, and the number of mitochondria per cell was counted manually by a blind observer.

**Statistical analysis.** Data are expressed as means ± SD. The Tukey multiple-comparison test was used to determine the significance of pairwise differences among three or more groups. P < 0.05 was considered significant.
RESULTS

Characteristics of experimental mice. Table 1 details the characteristics of four groups of mice at the end of the experimental period. The whole body and right kidney weights were significantly higher in db/db mice compared with db/m mice. The mean blood pressure (MBP) was significantly higher in db/db mice than in db/m mice. RSV did not affect changes in MBP. db/db mice exhibited markedly elevated blood glucose levels compared with db/m mice throughout the entire experiment. In db/db mice, treatment with RSV induced a partial improvement in blood glucose levels and glycated hemoglobin by the end of the experiments. Serum lipid profiles including total cholesterol, triglyceride, and free fatty acid levels were also significantly elevated in db/db mice compared with db/m mice; the increases in triglycerides and free fatty acids were partially rescued by RSV (Table 1). In addition, an impairment of glucose and insulin tolerance was evident in db/db mice relative to db/m mice (Supplementary Fig. 1), and high levels of fasting glucose and insulin (Table 1) indicating insulin resistance were also observed in db/db mice. Such alteration of insulin resistance in db/db mice was partially improved by treatment with RSV. There were no differences in body weight and food consumption between
Untreated and RSV-treated db/db mice. The 24-h urine volume was significantly larger in db/db mice compared with db/m mice, and this was partially reduced by treatment with RSV (data not shown).

Changes in urinary albumin excretion. To evaluate the effects of RSV on functional abnormalities in db/db mice, we measured the urinary albumin excretion. Values were markedly higher in db/db mice and RSV treatment significantly reduced such expansion. Figure 1B shows the results of quantitative analysis of mesangial matrix expansion in all groups. Although the ratio of mesangial matrix/glomerular area was markedly larger in db/db mice than in db/m mice, treatment with RSV significantly reduced this expansion.

Immunohistochemistry for fibronectin (Fig. 1A e–h and i–l) also showed a significantly higher score for renal glomerular and tubulointerstitial expression in db/db mice than in db/m mice (Fig. 1C and D). Treatment with RSV reduced the score for fibronectin in db/db mice but had no effect on db/m (Fig. 1C and D).

The number of cells positive for F4/80 (a macrophage marker) in the renal interstitial lesion was significantly higher in db/db mice than in db/m mice (Fig. 1A m–p), but this pattern was not found in the glomeruli (data not shown).

Treatment with RSV reduced the number of F4/80-positive cells in the renal interstitial lesions of db/db mice (Fig. 1E). These results indicate that RSV might improve glomerular and interstitial histological abnormalities including mesangial expansion, fibronectin accumulation and increased interstitial macrophage infiltration in the kidney of db/db mice.

Changes in urinary 8-OHdG excretion and mitochondrial oxidative damage in the kidney. Urinary 8-OHdG excretion was markedly higher in db/db mice compared with db/m mice but diminished after treatment with RSV (Fig. 2A). The 8-OHdG content (Fig. 2B) and subsequent deletion mutation (Fig. 2C) in the mtDNA isolated from the kidneys of db/db mice were significantly higher than in db/m mice. These mitochondrial alterations in mtDNA were not observed in the kidney of db/db mice treated with RSV. In addition, O$_{2}^{\cdot}$ production from the isolated renal mitochondria after stimulation with succinate and antimycin A was significantly increased in db/db mice, but treatment with RSV restored it to normal in db/db mice. In ex vivo experiments, the addition of RSV exogenously attenuated the levels of O$_{2}^{\cdot}$ from the renal mitochondria of db/db mice in a dose-dependent manner (Fig. 2D). Moreover, RSV could also scavenge O$_{2}^{\cdot}$ production from reaction of hypoxanthine and xanthine oxidase in a dose-dependent manner. These results suggest that the enhancement of both systemic oxidative damage and renal mitochondrial oxidative damage was observed in db/db mice and that RSV has antioxidative activity.

Changes in nitrotyrosine expression in the kidney. Figure 3A a–h show representative immunohistochemical staining for nitrotyrosine in the kidney. The semiquantitative

FIG. 3. Treatment with RSV suppresses diabetes-induced nitrotyrosine staining in the mouse kidney. A: Representative photomicrographs of renal nitrotyrosine expression. Data are results of independent experiments in each group with six mice per group. Original magnification: ×400 for glomerular nitrotyrosine (a–d) and ×100 for tubulointerstitial nitrotyrosine (e–h) staining. B and C: Semiquantitative scores for nitrotyrosine in glomerular and tubulointerstitial lesions. Data are means ± SD (n = 6, *P < 0.05 vs. other groups). (A high-quality digital representation of this figure is available in the online issue.)
scores for nitrotyrosine in both the glomerular and the tubulointerstitial lesions of the renal cortex were increased in db/db mice compared with those of db/m mice (Fig. 3B and C). Treatment with RSV reduced the scores in the glomeruli and tubulointerstitium of db/db mice but had no effect on the lesions of db/m mice (Fig. 3B and C). These results indicate that tyrosine nitration of proteins is enhanced in the kidney of db/db mice and that RSV seems to attenuate the effect.

Changes in Mn-SOD expression and activity in the kidney. The mRNA and protein expression of Mn-SOD was higher in db/db mice than in db/m mice (Fig. 4A–C). The Mn-SOD activity was significantly lower in the kidney of db/db mice compared with that of db/m mice (Fig. 4D). Nitrotyrosine immunoreactivity was significantly higher in Mn-SOD immunoprecipitates from the kidney of db/db mice than in that from db/m mice, and the increase in immunoreactivity was attenuated by treatment with RSV in db/db but not db/m mice (Fig. 4E and F). These findings suggest that Mn-SOD activity could be reduced by modifying tyrosine nitration in the kidneys of db/db mice.

mRNA levels of mitochondrial biogenesis–related genes and the enzyme activity of citrate synthase. To evaluate mitochondrial biogenesis, we assessed peroxisome proliferator-activated receptor γ coactivator (PGC)-1α, nuclear respiratory factor (NRF)-1, and cytochrome c oxidoreductase mRNA expression levels and mtDNA contents in the kidney. The citrate synthase activity was also measured in the kidney. All these were significantly higher in the kidneys of db/db mice than in that of db/m mice (Fig. 5A–E). These changes improved following treatment with RSV, consistent with the observed normalization of Mn-SOD activity and oxidative stress.

Electron microscopy. To confirm the beneficial effects of RSV on mitochondrial biogenesis, we examined the renal morphology in more detail by electron microscopy. The number and area of the mitochondria were significantly larger in renal proximal tubular cells of db/db mice compared with db/m mice, but treatment with RSV rescued these differences in db/db mice (Fig. 6A–C).

Changes in AMPK activation and SIRT 1 expression in the kidney. We assessed whether RSV activates AMPK in the kidney using immunoblotting for phosphorylation of AMPK. Activation of AMPK was significantly reduced in the kidney of db/db mice compared with db/m mice, and RSV did not alter AMPK activation in the kidney (Fig. 7A and B). In addition, SIRT1 expression was no different among the groups (Fig. 7A and C).

RSV exerts antioxidative effects in AMPK/SIRT1-independent mechanism in cultured renal proximal tubular cells. RSV attenuated intracellular ROS in both the SIRT1-knocked-down and DN-AMPK–overexpressing

FIG. 4. Mn-SOD expression and activity in the kidney. A: Mn-SOD mRNA expression in kidneys was quantified by real-time PCR and expressed as fold increase relative to db/m mice. Data are means ± SD (n = 9–11, #P < 0.05 vs. other groups). B: Mn-SOD protein expression in the kidney shown by representative immunoblots of Mn-SOD in protein extracts from the kidneys of mice of each group. Actin was loaded as an internal control. C: Quantitative analysis of Mn-SOD protein expression in the kidneys. Data are means ± SD (n = 4, #P < 0.05 vs. other groups). D: Mn-SOD activity in the kidney homogenate is expressed as fold increase compared with db/m mice. Data are means ± SD (n = 9–11, #P < 0.05 vs. other groups). Immunoreactivity to nitrotyrosine for immunoprecipitated Mn-SOD. Proteins from the kidneys of each group were immunoprecipitated with anti-Mn-SOD antibodies and blotted for nitrotyrosine antibodies. Representative results of Western blotting are shown (E), and the ratio to immunoprecipitated Mn-SOD is shown (F). Data are means ± SD (n = 6, #P < 0.05 vs. other groups).
renal proximal tubular cells as well as in control cells. These results indicate that RSV exerts antioxidative effects independent of the AMPK/SIRT1 pathway (Fig. 7D and E).

**DISCUSSION**

In this study, we showed the potential benefits of RSV in ameliorating the renal injury and the enhanced mitochondrial biogenesis with Mn-SOD dysfunction observed in the diabetic kidney. We also demonstrated that RSV seems to exert these effects by improving the oxidative stress status in the kidney via the scavenging of ROS, normalization of Mn-SOD dysfunction, and partial rescue of glucose-lipid metabolism. Also, such antioxidative effects of RSV could be exerted in an AMPK/SIRT1-independent mechanism.

First, we showed that RSV improved renal functional and histological abnormalities such as albuminuria, mesangial expansion, glomerular and interstitial fibrocartilage accumulation, and interstitial macrophage infiltration in the kidney of db/db mice, a type 2 diabetes animal model. Oxidative stress has been implicated in the pathogenesis of diabetic nephropathy, and high glucose-induced ROS in renal mesangial or tubular cells contribute to overproduction of extracellular matrix proteins and inflammation (31,32). Because it has been reported that RSV is a robust scavenger of ROS (6,7), we assessed whether RSV has beneficial effects against diabetes-induced systemic and renal oxidative stress by measuring urinary 8-OHdG excretion and renal immunostaining for nitrotyrosine. Moreover, not only are mitochondria an important source of ROS, but also they themselves can be damaged by ROS. Therefore, we also assessed renal mitochondrial oxidative stress by measuring accumulation of mitochondrial 8-OHdG and D-17 deletion of mtDNA, which have been observed in diabetic nephropathy (33) and aging (24). In the current study, renal nitrotyrosine expression and mitochondrial oxidative damage indicated systemic, renal and particularly mitochondrial enhanced oxidative stress in the kidney of db/db mice, and there was clear attenuation of these markers following treatment with RSV. In addition, we showed that isolated mitochondrial O$_2^-$ production by stimulation with succinate and antimycin A was increased in db/db mice, and the RSV could scavenge ROS from the mitochondria.

The mitochondria are an important source of ROS in diabetes (9), and ROS metabolism in the mitochondria is mainly regulated by Mn-SOD, which is an important antioxidative enzyme in the mitochondria. In the diabetic state, high glucose- or FFA-induced overproduction of ROS from the mitochondria is inhibited by overexpression of Mn-SOD in vascular cells and tissues (9,34–37). Moreover, heterozygous Mn-SOD deficient mouse, which only have 50% of the Mn-SOD activity seen in wild-type mice, showed O$_2^-$-induced mitochondrial oxidative damage (38), together with massive glomerulosclerosis, tubulointerstitial damage and inflammation including macrophage infiltration in the kidney (39). Therefore, regulation of ROS metabolism...
in the mitochondria via Mn-SOD function is an important protective factor in managing diabetic vascular complications including nephropathy. It is also known that tyrosine nitration at the active site of Mn-SOD is associated with reduction in enzymatic activity in the kidneys of several disease models (26,40–42). In the current study, we showed reduced Mn-SOD activity even when the expression of Mn-SOD was increased, and the former was probably caused by increased tyrosine nitration in the kidney of db/db mice. RSV might reduce tyrosine nitration of Mn-SOD and rescue the activation, resulting in improvement of mitochondrial oxidative stress and renal injury in diabetic kidney. Thus, RSV might ameliorate systemic, renal, and particularly mitochondrial oxidative stress in diabetes via the direct scavenging of ROS and normalization of the Mn-SOD function.

It has been reported recently that reduced mitochondrial biogenesis in insulin resistant tissues such as skeletal muscle, liver, or fat is associated with the pathogenesis of type 2 diabetes (11). In addition to its function as a ROS scavenger, several reports have implicated RSV in activating the AMPK/SIRT1 pathway to induce mitochondrial biogenesis (14), leading to life span prolongation and improvement of high-fat diet–induced metabolic impairment such as obesity and insulin resistance (12,13). We therefore examined mitochondrial biogenesis in the kidney based on mtDNA contents, mitochondria area and number, citrate synthase activity and overexpression of PGC-1α, NRF-1, cytochrome c oxidoreductase, and Mn-SOD. Interestingly, these factors were all enhanced in the kidney of db/db mice compared with db/m mice, and were rescued by RSV treatment, consistent with attenuation of systemic and renal mitochondrial oxidative stress including tyrosine nitration of Mn-SOD. Moreover, RSV did not alter AMPK activation or induction of Mn-SOD expression in the kidney. We also showed that RSV attenuated intracellular ROS in both the SIRT1 knocked-down and the DN-AMPK–overexpressing renal proximal tubular cells. These results suggest that systemic and/or renal mitochondrial oxidative stress contributes to the enhanced mitochondrial biogenesis in the kidney of the db/db mice and that RSV might improve mitochondrial biogenesis through the attenuation of oxidative stress, rather than through the activation of the AMPK/SIRT1 pathway. In this regard, Shen et al. (20) demonstrated that oxidative stress–induced mitochondrial biogenesis was increased in the myocardium of OVE26 diabetic mice as a possible compensatory reaction against oxidative stress–induced mitochondrial damage. Moreover, they showed that the myocardium-specific Mn-SOD transgenic mice crossed with OVE26 diabetic mice showed

**FIG. 6.** Electron microscopy of kidney. A: Representative micrographs of proximal tubular cells from mice treated with RSV. Scale bar = 2 μm. Quantitative assessment of number (B) and area (C) of mitochondria in proximal tubular cells in mice treated with RSV. Data are means ± SD (n = 3, #P < 0.01 vs. other groups).
improvement of oxidant-induced mitochondrial biogenesis and dysfunction (37). Therefore, we suggest that the enhanced mitochondrial biogenesis in the kidney of db/db mice might also be a compensatory response to oxidative stress–induced mitochondrial damage; however further study is needed to elucidate the role of enhanced mitochondrial biogenesis associated with Mn-SOD dysfunction. RSV has also been shown to reduce elevated blood glucose levels and metabolic impairment in diabetes, to be associated with mitochondrial biogenesis through the AMPK/SIRT1 activation pathway, as discussed above (12,13,43). In the current study, the elevated levels of glucose, glycated hemoglobin, triglycerides, and free fatty acids and impairment of glucose/insulin tolerance in db/db mice improved to some extent by treatment with RSV. It is therefore possible that RSV acts as an enhancer of mitochondrial biogenesis through AMPK/SIRT1 activation in liver and skeletal muscle, resulting in demonstrated improvements in abnormal glucose-lipid metabolism in db/db mice. In fact, we found that the phosphorylation of AMPK was reduced in the liver of db/db mice, and RSV could restore its alteration (data not shown). Therefore, RSV is likely exerting some of its effects via improvement of glucose homeostasis, and the systemic improvement of metabolism might at least in part contribute to the amelioration of renal oxidative stress and renal injury.

In conclusion, our study indicated that the enhanced mitochondrial biogenesis with Mn-SOD dysfunction by tyrosine nitration was observed in the diabetic kidney. RSV seems to improve these functional and histological abnormalities and ameliorate the enhanced mitochondrial biogenesis in diabetic kidney, possibly by attenuating the oxidative stress through scavenging of the ROS, by the normalization of the Mn-SOD dysfunction in an AMPK/SIRT1-independent mechanism, and by the partial improvement of the glucose and lipid metabolism.

ACKNOWLEDGMENTS

This work was supported by a Grant-in-Aid for Scientific Research (21591148) to D.K., and the grant from the Uehara Memorial Foundation to D.K.

No potential conflicts of interest relevant to this article were reported.

M.K. collected and analyzed the data and wrote the manuscript. S.K. collected and analyzed the data and contributed to discussion. N.I. collected and analyzed the data. D.K. contributed to discussion and reviewed and edited the manuscript.

The authors thank Yuki Tanaka and Eiko Kobori for the technical support on fibronectin immunohistochemistry and maintenance of animals and collecting their physiological data. The authors also thank Dr. Issa F.G., Word-Medex Pty Ltd. for help with preparing the manuscript.
