NON LEFT-ORDERABLE SURGERIES ON NEGATIVELY TWISTED TORUS KNOTS

KAZUHIRO ICHIHARA AND YUKI TEMMA

Abstract. We show that certain negatively twisted torus knots admit Dehn surgeries yielding 3-manifolds with non left-orderable fundamental groups.

1. Introduction

In [1], Boyer, Gordon and Watson raised the following conjecture, which is now called the L-space conjecture: An irreducible rational homology 3-sphere is an L-space if and only if its fundamental group is not left-orderable. Here a rational homology 3-sphere is called an L-space if \( \text{rk} \hat{HF}(M) = \left| H_1(M, \mathbb{Z}) \right| \) holds, and a non-trivial group \( G \) is called left-orderable if there exists a strict total order \( < \) on \( G \) such that if \( g < h \), then \( fg < fh \) holds for any \( f, g, h \in G \). See [1] for more details.

One of the known approaches to the conjecture is by using Dehn surgery, for it gives a simple way to construct many L-spaces at once. For example, in [8], it is shown that a knot \( K \) in the 3-sphere \( S^3 \) admits a Dehn surgery yielding an L-space, then any Dehn surgery on \( K \) along a slope \( r \) with \( r \geq 2g(K) - 1 \) yields an L-space, where \( g(K) \) denotes the genus of \( K \).

Thus it is natural to ask if Dehn surgeries on a knot yielding 3-manifolds with non left-orderable fundamental groups give L-spaces.

There are several known results on this line. For example, recall that finite groups cannot be left-orderable, and 3-manifolds with finite fundamental groups are known to be L-spaces. Thus a good target for such study is the class of knots admitting Dehn surgeries creating 3-manifolds with finite fundamental groups. A well-known class of the knots with such surgeries is that of twisted torus knots, originally given by Dean [4].

Here a (positively) twisted torus knot in \( S^3 \) is defined as the knot obtained from a torus knot by adding (positive) full twists along an adjacent pair of strands. See Figure 1 for example.

In fact, Clay and Watson considered Dehn surgeries on positively twisted torus knots in [2]. Precisely, they showed that $r$-surgery on a positively $s$-twisted $(3,3k+2)$-torus knot gives a 3-manifold with non left-orderable fundamental group if (1) $s \geq 0$ and $k = 1$, or (2) $s = 1$ and $k \geq 0$.

This can be comparable to the result by Vafaee [3] showing that such positively twisted torus knots admit L-space surgery. Precisely, he showed that $r$-surgery on a $(p,kp \pm 1)$-torus knot with $s$ full twists on $u$ adjacent strands gives an L-space if (1) $u = p - 1$, (2) $u = p - 2$ and $s = 1$, or (3) $u = 2$ and $s = 1$, for $p \geq 2$, $k \geq 1$, $s > 0$, and $0 < u < p$. In the case of $p = 3$, a positively 2-twisted $(3,q)$-torus knot $(q > 0, s \geq 1)$ is of genus $q + s - 1$, and so, it follows that $r$-surgery on that knot gives a 3-manifold with non left-orderable fundamental group if $r \geq 2q + 2s - 3$.

Soon after, Christianson, Goluboff, Hamann, and Varadaraj gave further extensions in [3]. They actually show that $r$-surgery on a positively $s$-twisted torus knot of type $(3,3v + 2)$ with $s,v \geq 0$ yields a closed 3-manifold with non left-orderable fundamental group if $r \geq 3(3v + 2) + 2s$.

We remark that all the above results concern only positively twisted torus knots. Thus it seems natural to ask what happens for negatively twisted torus knots. In this paper, we show the following.

**Theorem 1.1.** Let $K$ be the $(-1)$-twisted $(3,3v + 2)$-torus knot with $v \geq 0$. Then $r$-surgery on $K$ yields a 3-manifold with non left-orderable fundamental group if $r \geq 3(3v + 2) - 2$.

Actually, the $(-1)$-twisted $(3,3v + 2)$-torus knot is equivalent to the 1-twisted $(3,3v + 1)$-torus knot with $v \geq 0$. Thus, the result in [3] guarantees that $r$-surgery on the knot yields a 3-manifold with non left-orderable fundamental group if $r \geq 3(3v + 2) + 1$. That is, our theorem above can improve their bound slightly.

## 2. Proof

We start with recalling our technical main result in [3].

**Theorem (5 Theorem 1.1).** Let $K$ be a knot in a closed, connected 3-manifold $M$. Suppose that the knot group $\pi_1(M - K)$ admits the presentation

$$(a, b \mid (w_1a^mw_1^{-1})b^{-r}(w_2^{-1}a^nw_2)b^{r-k})$$

Here $w_1, w_2$ are arbitrary words with $m,n \geq 0$, $r \in \mathbb{Z}$, $k \geq 0$. Suppose further that $a$ represents a meridian of $K$ and $a^{-s}wa^{-t}$ represents a longitude of $K$ with $s,t \in \mathbb{Z}$ and $w$ is a word which excludes $a^{-1}$ and $b^{-1}$. Then if $q \neq 0$ and $p/q \geq s + t$, then Dehn surgery on $K$ along the slope corresponding to $p/q$ with respect to the meridian-longitude system yields a closed 3-manifold with non left-orderable fundamental group.
Thus, to prove Theorem 1.1 we show the following.

**Proposition 2.1.** Let $K$ be the $u$-twisted torus knot of type $(3, 3v + 2)$ in $S^3$ with $u \in \mathbb{Z}, v \geq 0$. Then the knot group $\pi_1(S^3 - K)$ admits the presentation

$$\langle a, b \mid (w_1 a^m w_1^{-1}) b^{-r} (w_2 a^n w_2) b^{-k} \rangle$$

with $m = n = 1, r = u + 1, k = 1, w_1 = (ba)^{u+1}, w_2 = (ba)^v$. Furthermore the generator $a$ represents a meridian of $K$ and the preferred longitude of $K$ is represented as $a^{-s} w a^{-t}$ with $s = 2u + 3(3v + 2) + 1, t = -1$ and $w = ((ba)^{u+1})(ba)^v b$.

In the following, we will obtain a Wirtinger presentation of such a knot group. Note that, in [2, 3, 5], all the presentations for knot groups are obtained by using Heegaard splitting of $S^3$.

Let $L$ be the three component link, and $D$ the diagram of $L$ illustrated in Figure 2.

As in Figure 3 we label $\alpha, \beta, \gamma, \xi, \psi, \delta_1, \delta_2, \delta_3, \delta_4, \delta_5, \delta_6, \delta_7$ to the arcs in the diagram, and $P_1, \cdots, P_{12}$ to the twelve crossings in the diagram.

Next we construct relators for the crossing of $D$ as follows.

\begin{align*}
P_1 : & \quad \xi \alpha \delta_1^{-1} \alpha^{-1} \\
P_2 : & \quad \delta_1 \beta \delta_2^{-1} \beta^{-1} \\
P_3 : & \quad \delta_2 \gamma \xi \gamma^{-1} \\
P_4 : & \quad \xi^{-1} \alpha \xi \gamma^{-1} \\
P_5 : & \quad \xi^{-1} \beta \delta_3^{-1} \\
P_6 : & \quad \xi^{-1} \gamma \xi \delta_4^{-1} \\
P_7 : & \quad \delta_5^{-1} \gamma \delta_3 \gamma^{-1} \\
P_8 : & \quad \delta_6^{-1} \gamma \delta_4 \gamma^{-1} \\
P_9 : & \quad \psi \delta_5 \delta_7^{-1} \delta_5^{-1} \\
P_{10} : & \quad \delta_7 \delta_6 \psi \delta_5^{-1} \delta_6^{-1} \\
P_{11} : & \quad \psi^{-1} \delta_5 \psi \alpha^{-1} \\
P_{12} : & \quad \psi^{-1} \delta_6 \psi \beta^{-1}
\end{align*}
Moreover, the following are obtained from the above.

\[
\begin{align*}
\delta_1 &= \alpha^{-1}\xi\alpha \\
\delta_2 &= \gamma\xi\gamma^{-1} \\
\delta_3 &= \xi^{-1}\beta\xi \\
\delta_4 &= \xi^{-1}\gamma\xi \\
\delta_5 &= \gamma\delta_3\gamma^{-1} = \gamma\xi^{-1}\beta\xi\gamma^{-1} \\
\delta_6 &= \gamma\delta_4\gamma^{-1} = \gamma\xi^{-1}\gamma\xi\gamma^{-1}
\end{align*}
\]

Moreover, from the relations at \(P_{11}\) and \(P_{12}\), we have \(\delta_5 = \psi\alpha\psi^{-1}\) and \(\delta_6 = \psi\beta\psi^{-1}\). From these, together with the relations at \(P_3\) and \(P_{10}\), we have \(\psi^{-1}\beta^{-1}\alpha^{-1}\psi\alpha\beta\).

From these, by erasing \(\delta_1, \cdots, \delta_7\), we have the following lemma consequently. Here let \(l_1\) be an upper trivial component, \(l_2\) be a lower trivial component, and \(l_0\) be the other component in Figure 2.

**Lemma 2.2.** For the three component link \(L\) in Figure 2, the link group \(\pi_1(S^3-L)\) admits the presentation

\[
\langle \alpha, \beta, \gamma, \xi, \psi \mid \xi^{-1}\gamma^{-1}\beta^{-1}\alpha^{-1}\xi\alpha\beta\gamma, \xi^{-1}\alpha\xi\gamma^{-1}, \psi^{-1}\gamma\xi^{-1}\beta\xi\gamma^{-1}\psi\alpha^{-1}, \psi^{-1}\gamma\xi^{-1}\beta\xi\gamma^{-1}\psi\alpha^{-1}, \psi^{-1}\gamma\xi^{-1}\beta\xi\gamma^{-1}\psi\alpha^{-1} \rangle
\]

Furthermore, for the component \(l_1\) of \(L\), a meridian is represented by \(\xi\) and the preferred longitude is represented by \(\alpha\beta\gamma\). For the component \(l_2\) of \(L\), a meridian is represented by \(\psi\) and the preferred longitude is represented by \(\alpha\beta\). Also, for the component \(l_0\), a meridian is represented by \(\alpha\) and a longitude is represented by \(\xi\xi\gamma^{-1}\psi\xi\gamma^{-1}\psi\).

In fact, \(u\)-twisted torus knots of type \((3,3v+2)\) are obtained from the link \(L\) by adding \(u\) full twists along the component \(l_2\), and \(v\) full twists along the component \(l_1\). We note that adding \(v\) full twists along \(l_1\) is realized by the Dehn surgery on...
We note that Equation (1) is equivalent to (2) relations.

It then follows that Equations (1) and (2) are equivalent by considering the inverse.

Thus the relators of the presentation are represented by using $g$ and $h$ as follows.

Thus the relators of the presentation are represented by using $g$ and $h$ as follows.

We note that Equation (1) is equivalent to

and Equation (2) is equivalent to

It then follows that Equations (1) and (2) are equivalent by considering the inverse.

Also note that the last equation corresponds to the commutativity of the meridian and longitude for the component $l_2$, and so, can be obtained from the other relations.

Therefore, we have the following presentation of the knot group of $K$,

\[
\langle g, h \mid g^2(h^{-v}g)^ug^{-v-1}(h^{-v}g)^{-u}h^{-2v-1} \rangle
\]
and is equivalent to the following.
\[ \langle g, h \mid h^{v+1}g^{-1}(h^{-v}g)^{-u}g^{-2}h^{2u+1}(h^{-v}g)^{u} \rangle \]

Furthermore, by setting \( a = g^{-1}h^{v+1} \) and \( b = ha^{-1} \), i.e., \( h = ba \) and \( g = h^{v+1}a^{-1} = (ba)^{v+1}a^{-1} = (ba)^v b \), we have the following.
\[ \langle a, b \mid (ba)^{v+1}a(ba)^{-v-1}b^{-v-1}(ba)^{-v}a(ba)^vb^u \rangle \]

Consequently the knot group \( \pi_1(S^3 - K) \) admits the presentation
\[ \langle a, b \mid (w_1a^n w_1^{-1})b^{-r}(w_2^{-1}a^n w_2)b^{-r-k} \rangle \]
with \( m = n = 1, r = u + 1, k = 1, w_1 = (ba)^{v+1}, w_2 = (ba)^v \).

By Lemma 2.2 a meridian of \( K \) is represented by \( \alpha \). This \( \alpha \) is represented by \( h^{v+1}g^{-1} \) which equals to \( a \). Also by Lemma 2.2 a longitude of \( K \) is represented by \( \xi \tilde{\gamma}^{-1} \psi \tilde{\gamma}^{-1} \psi \). This element is represented by \( h^{v+1}(g(h^{-v}g)^v)^2 \) which equals to \( (ba)^{v+1}(ba)^vb^u+1(ba)^v(ba)^v+1 \). Adding \( a^{-1} \), we have \( a^{-1}(ba)^vb^{u+1}(ba)^vb^v+1(ba)^v+1 \). Finally, as noted in the paragraph just below [2 Proposition 3.2], the presentation of the preferred longitude of \( K \) is obtained from the above by adding \( a^{-3(3u+2)-2u} \) as follows.
\[ a^{-3(3u+2)-2u-1}\left((ba)^vb^{u+1}\right)^2(ba)^v b \]

Therefore the preferred longitude of \( K \) is represented as \( a^{-s}wa^{-t} \) with \( s = 2u + 3(3u+2) + 1, t = -1 \) and \( w = ((ba)^vb^{u+1})^2(ba)^v b \).

This completes the proof of Proposition 2.1 since \( u \) is any integer. \( \square \)

We remark that the condition for the presentation of the preferred longitude such as \( w \) is a positive word in [5 Theorem 1.1] holds in the case of \( u = -1 \), although it does not hold in the case of \( u \leq -2 \).
