Wilson punctured network defects in 2D $q$-deformed Yang-Mills theory

Abstract

In the context of class S theories and 4D/2D duality relations there, we discuss the skein relations of general topological defects on the 2D side which are expected to be counterparts of composite surface-line operators in 4D class S theory. Such defects are geometrically interpreted as networks in a three dimensional space. We also propose a conjectural computational procedure for such defects in two dimensional $SU(N)$ topological $q$-deformed Yang-Mills theory by interpreting it as a statistical mechanical system associated with ideal triangulations.

1 Introduction

Recently, many interacting superconformal field theories (SCFTs) have been discovered whose definitions based on Lagrangians are not known yet. In particular, there is a certain group of 4D theories often called “class S theory” which are obtained as twisted compactifications of the 6d $\mathcal{N}=(2,0)$ SCFTs on Riemann surfaces $C$ with punctures \[1,3\]. Interestingly, even though almost all of the SCFTs have no definition based on the Lagrangians, some of their BPS observables have been evaluated assuming the dualities following their geometrical constructions. In particular, for theories with $\mathcal{N}=2$ Lagrangian descriptions, their partition functions on the squashed four-sphere $S^4_b$ \[4,5\] and the superconformal indices (SCIs) \[6\] (in the Schur limit) or equivalently partition functions on $S^1 \times_q S^3$ \[7\] were computed. Based on their explicit expressions, it was recently suggested that many class S theories beyond the Lagrangian definition \[1\] have alternative effective descriptions by some 2D theories: Liouville/Toda CFTs for $S^4_b$ case \[13,14\] and 2D topological $q$-deformed Yang-Mills for $S^1 \times_q S^3$ case \[15,17\]. Indeed, in addition to the partition functions, these 4D/2D dualities also offer new geometrical descriptions of supersymmetry defects in such SCFTs, which are main subjects of this paper.

First, let us focus on the 4D gauge theory. In particular, there are supersymmetric Wilson-'t Hooft line operators \[18–26\] and half-BPS surface operators \[27–33\]. It is considered that both defects come from codimension-four defects appearing in 6D $\mathcal{N}=(2,0)$ SCFTs \[2\] and both have the same origin in 6D. But their appearances in those 2D theories on $C$ look totally different. The 4D line operators correspond to Verlinde network operators/Wilson network operators in the Liouville-Toda CFTs/q-deformed Yang-Mills theories, see \[38–41\] for the geometrical viewpoint, \[42–48\] for the Verlinde network and \[49–55\] for the Wilson network. However, there is a serious problem left: How can we compute the expectation values of general network defects in the 2D $q$-deformed Yang-Mills theories ? \[3\] Naively speaking, it seems to be enough to replace ordinary Lie groups by “quantum group” as gauge groups at mathematical level. Indeed, the rigorous definition of Wilson loops without junctions in that case was given in \[53\] based on quantum groups, but its extension to any networks is not obvious yet for several reasons. Furthermore, even if it can be well-defined, it is not useful for the actual computations because it needs the general invariant tensors in the quantum group sense. Instead of giving rigorous definitions, we will propose the direct procedure to obtain the conjectural expressions in Sec. 2. The most important evidence for this proposal is the reproduction of several skein relations as remarked later.

On the other hand, the 4D surface operators are mapped into (fully degenerate) vertex operators/difference operators in the CFTs/Yang-Mills theories, see \[43,47,56\] and \[32\].

---

\[1\] In this paper, we focus on the Riemann surface compactifications with more than two regular punctures and no irregular ones. There are generalized proposals for non-SCFTs and Argyres-Douglas theories which need such irregular punctures \[2,8,12\].

\[2\] Precisely speaking, some surface operators can also come from codimension-two defects in the 6D theory \[34,37\]. However, we do not pay attentions to them in this paper.

\[3\] See \[48\] for the Verlinde networks.
57–61. Geometrically, they can be represented as special punctures on the Riemann surface in both the set-ups. Here let us consider a situation in which both line operators and surface operators coexist 62. This is the main subject in this paper.

There arise two questions: 1. Can we describe their skein relations on the geometrical side? 2. How can we extend the previous conjectural formula for closed Wilson network defects to these more general cases? A key observation to answer these questions is as follows. On both the Liouville/Toda CFT and the $q$-deformed Yang-Mills theory, the concept of crossings of networks exists and, in fact, they correspond to the ordering of corresponding half-BPS line operators in one space direction determined by the unbroken supersymmetry in 4D gauge theory 25,26,55,69. Then, the existence of crossings among several networks suggests that there is a hidden direction which is exactly identified with one of physical directions on the 4D gauge theory side. In other words, there appears a three dimensional geometry combined with the 2D space $C$ and one of 4D directions which is determined by the unbroken supersymmetry for the half-BPS loop operators. This is the more familiar story in RCFTs whose conformal blocks are the wave functions of the corresponding 3D Chern-Simon theories 63,64. See also 65,66 as for Verlinde loop operators in the Liouville CFT. We must note that the closer story exists for $q$-deformed Yang-Mills theory 54,67,68 but we do not know the precise relation between two systems. When we recall that the expectation values of BPS loops are independent of the positions on that direction 25,26,69, it is natural to speculate that the networks are still topological in the new geometry. In this new three dimensional geometry, codimension four defects are expressed as knot with junctions and both surface defects and line defects are on the same ground. We refer the corresponding defects in the $q$-deformed Yang-Mills theory to as “punctured networks”, which are the central subjects in Sec. 3 and describe the answer to the first question.

In Sec. 4, we combine the two results in previous two sections and give the expectation values formula for general punctured networks, which is the answer to the above second question. In the Appendix, A we develop the method to evaluate the proposed formula in Sec. 2 and summarize some mathematics appearing there. Using them, we prove that our proposal indeed reproduces a few fundamental skein relations in the following Appendix. B. This check gives a strong evidence that our proposal of the formula works well. The Appendix. C is the complement of charge/network correspondence discussed in 55. We can expect the same structure for the composite surface-line systems.

2 Closed Wilson network defects in 2D $q$-deformed Yang-Mills

In this section, we see how the expectation values of any closed Wilson network defects can be evaluated. Here “closed” means that the networks do not touch on general punctures.

4If we replace the 4-manifold on which the gauge theory is defined by the squashed 4-sphere $S^4_b$, there are locally two such directions which are exchanged under the flip from $b$ to $b^{-1}$ 5. Here we focus on either direction.
coming from codimension two defects in 6D SCFTs not codimension four ones. We divide
the evaluation procedure into two steps: giving the computational procedures for special
cases (See Sec. 2.3) and then constructing the general cases by using them (See Sec. 2.1).
However, we will explain these two steps in the reversed order by starting the general
cases and then by decomposing them into several special building blocks for which we
will give the procedure.

The organization of this section is as follows. In Sec. 2.1, we show the procedure to
obtain the special building blocks from the general set-ups. Next, in Sec. 2.2, we review
some properties of 2D $q$-deformed Yang-Mills theory and class S theories needed later.
In Sec. 2.3, we go back to the evaluation of defect expectation values. There, we map
such evaluations for special building blocks into the computations of partition functions of
statistical mechanical systems with infinite degrees of freedom. The construction of such a
mapping and giving the Boltzmann factor are the main points. We see some applications
to a few concrete theories in Sec. 2.4 and make a few comments on the above mapping of
$\mathcal{R}$-matrix in a special case in Sec. 2.5.

First of all, we recall some notations and properties needed in this paper. See also
App. A as for the Lie algebra notation. We assume the following properties for closed
networks (See [39,48] and [55] for the details):

1. Each network consists of trivalent junctions and arrowed edges with a charge $a \in \{0, 1, 2, \ldots, N - 1\} \simeq \mathbb{Z}_N$ on each. Each charge corresponds to the fundamental
representations $\wedge^a \Box$ of $SU(N)$ which form the minimal set to generate all the ir-
reducible representations. Notice also that edges with 0 can be removed and we
ignore them hereafter.

Flipping arrow is equivalent to the replacement by the charge conjugate represen-
tation

$$ R \rightarrow R^* $$ \hspace{1cm} (2.1)

In particular, as we only consider the fundamental representations $\wedge^a \Box$, this opera-
tion corresponds to $a \rightarrow N - a$.

If we use an edge labelled by an irreducible representation $R$, we interpret it as a
bunch of edges according to a polynomial expression of $R$ of $SU(N)$ representation
ring generators of $\wedge^a \Box$.

2. There is the charge conservation on each junction. More precisely, if we have all
three inflowing/outgoing edges with charges $a, b$ and $c$, they must satisfy $a + b + c = 0$
mod $N$. On forgetting to take the $N$-modulo operation, there are two possibilities:
$a + b + c = N$ or $2N$. We call the former one $(a, b, c)$-junction for both inflowing
one and outflowing one, see Fig. 1. If $a + b + c = 2N$, the redefinition $a' = N - a,$
$b' = N - b$ and $c' = N - c$ makes $a' + b' + c' = N$ and the exchange between inflowing
and outflowing, and we have $(N - a, N - b, N - c)$-junction for the latter case.

4
3. Any crossing can be resolved into a network without any crossing. In particular, in \[55\], we identified such relations in class S theories, referred to as “crossing resolutions”, with those already found in \[70\] like

\[
q^{ab} \sum_{i=0}^{s} q^{-i} = q^{a+b-i} \quad (2.2)
\]

where \(s = \min(a, b, N-a, N-b)\) and \(a, b = 0, 1, 2, \ldots, N-1\). On the right hand side, there are no crossings. Therefore, we can remove all the crossings from the network by applying the above relation to each but have a sum of several networks instead.

**Skein relations**

Once we have introduced the 3D geometry discussed in Sec. \[3.2\], the meaning of skein relations are exactly same as those in the knot theory. Instead, throughout this paper, we use the skein relations in the following sense.

Let \(W_q[\Gamma](\{a\})\) be the expectation value of the 2D Wilson network operator associated with \(\Gamma\) in the 2D \(q\)-deformed Yang-Mills theory. \(\{a\}\) are all holonomies around punctures of \(C\). And let us consider two sub graphs \(\gamma_A\) and \(\gamma_B\). For any pair of two graphs \(\Gamma_A\) and \(\Gamma_B\) which include \(\gamma_A\) and \(\gamma_B\) respectively but are same on removing these sub graphs, when the equality shown just below always holds true, we identify \(\gamma_A\) and \(\gamma_B\) and write this as \(\gamma_A \sim \gamma_B\). The equality is

\[
W_q[\Gamma_A](\{a\}) = C_q(\gamma_A \rightarrow \gamma_B)W_q[\Gamma_B](\{a\}) \quad (2.3)
\]

\[5\] There is an important caution. As explained in \[55\], there are two different conventions called “Liouville-Toda” convention and “\(q\)-deformed Yang-Mills” one. Although we focus on the 2D \(q\)-deformed Yang-Mills theory, we also use the former convention which is mostly used in the context of the 4D/2D duality, after this section. There, instead of \(q\), we use another symbol \(q\) which is related to \(q\) by \(q = q^{1/2}\). Note also that the skein relations in the \(q\)-deformed Yang-Mills convention are obtained under the replacement of \(q\) by \(-q^{1/2}\), where the additional minus sign appears compared to the above actual relation. This is because the normalizations of the junctions differ in two conventions.
where $C_q(\gamma_A \rightarrow \gamma_B)$ is a function of only $q$ and independent of all holonomies around punctures and is also determined by $\gamma_A$ and $\gamma_B$ only. Notice that, in many cases, this relation is enough local and independent of the choice of $C$. Now we have the equivalence relations \( \sim \) and refer to them as the "skein relations" hereafter.

Finally, we make a few comments. Under the parameter identification $q = e^{2\pi i b}$, where $b$ is a physical parameter in the Liouville/Toda CFT, the skein relations are common both in the CFTs and in the 2D $q$-deformed Yang-Mills theory. This is because the skein relations are expected to be the local relations about codimension four defects in the 6D $\mathcal{N}=(2,0)$ SCFTs and to be independent of the four dimensional global background geometries, namely, the choice of $S^4_b$ or $S^1 \times q S^3$.

Notice also that the crossing skein relation may suggest the new direction of the 2D $q$-deformed Yang-Mills theory but the appearance is not so obvious in this 2D theory itself. However, this class S picture from the 6D $\mathcal{N}=(2,0)$ SCFTs strongly suggest that. See also Sec 3.2.

2.1 Reduction onto special cases

Here we see how the most general pairs of the Riemann surface and defects on it decompose into the several special ones as the building blocks.

Let \( C \) be a Riemann surface with genus $g$ and $n$ punctures and $\Gamma$ be any closed networks on it. To each puncture, we assign a holonomy which corresponds to the fugacity in the SCI language. On the types of punctures and their holonomies, see the review in Sec. 2.2 later. $\Gamma$ may consist of several disconnected components and we write the decomposition as $\Gamma = \sqcup_{\alpha} \hat{\Gamma}_\alpha$. Next, consider a neighborhood of $\hat{\Gamma}_\alpha$ which is sometimes called a ribbon graph or a fat graph. This fat graph denoted by $\hat{C}_\alpha$ is a two dimensional open surface and its boundary consists of several copies of $S^1$. See Fig. 2. Cutting along the boundaries of $\hat{C}_\alpha$, we have a decomposition of $C$. By the above construction, in addition to $\hat{C}_\alpha$'s, there are other connected components denoting $\tilde{C}_A$ which have no network defects. Note that

\[ \text{In all examples we know, } C_q \text{ is a product of a polynomial of } q^\frac{1}{2} \text{ and a monomial with a negative rational power of } q. \]
we identify each boundary isomorphic to $S^1$ with a puncture.

Let us make one comment on the topological property of $\hat{C}$. If $\hat{\Gamma}$ has $2\ell$ ($\ell > 0$) junctions and the boundary of its fat graph $\hat{C}$ is isomorphic to $k$ copies of $S^1$, $\hat{C}$ is the $k$-punctured genus $(\ell - k)/2 + 1$ Riemann surface. Note that its Euler character is $-\ell$.\footnote{Let $e, v (= 2\ell)$ and $f$ be the number of edges, junctions of $\hat{\Gamma}$ and regions in $\hat{C}$, respectively. By construction, $f = k$ holds true. The closedness of the network $\hat{\Gamma}$ and the trivalence property of junctions also say $2e = 3v$. The Euler’s theorem applied to $\hat{C}$ ignoring all the punctures gives $2 - 2g = f - e + v$. Combined with all, we finally have the claim $\chi_{\hat{C}} = 2 - 2g - k = -\frac{1}{2}v = -\ell$.}

In particular, when $\hat{\Gamma}$ is a pure loop without junctions, $\hat{C}$ is the twice-punctured sphere.

Now $\hat{C}$ consists of two types of connected components : $\hat{C}_\alpha$ which is homotopic to $\hat{\Gamma}_\alpha$ and $\tilde{C}$ for which we already know how to compute their partition functions as remarked later. Since we can reconstruct the expectation values of the original system by gluing together as shown around (2.7), all we have to do is know the expectation values for each pair $(\hat{C}_\alpha, \hat{\Gamma}_\alpha)$. Before showing that procedure (Sec. 2.3), we review several facts needed for the complete reconstruction and later discussions.

### 2.2 Brief reviews on the partition functions and loops expectation values

In this section, we review the following five points:

0. Overall renormalization factors

1. Formula for no network defect cases

2. Gluing (= gauging process on the 4D side)

3. Formula in the presence of loops

4. Partially Higgsing or partially closing on punctures.

See \[54, 71\] on the $q$-deformed Yang-Mills, and see also a review \[52\] when $q = 1$. Refer to \[1, 15, 72\] on the class S punctures.

Here we define $q$-number as

$$[n]_q := \frac{q^{n/2} - q^{-n/2}}{q^{1/2} - q^{-1/2}}. \hspace{1cm} (2.4)$$

$\dim_q R$ denotes the $q$-dimension of an irreducible representation $R$. See \[A.7\] for its definition. If we want to change the convention from $q$-deformed Yang-Mills one to Liouville-Toda one, all we have to do is to replace the above $q$-number by quasi $q$-number

$$\langle n \rangle_q := (-1)^{n-1} \frac{q^n - q^{-n}}{q - q^{-1}}. \hspace{1cm} (2.5)$$
0. Overall renormalization factors

On the comparison between the SCIs in the Schur limit and \(q\)-deformed Yang-Mills partition functions, there is a bit difference between two: There are additional overall factors in the SCIs. It consists of two types: a prefactor depending only on \(q\) and renormalization factors \(K(a, q)\) assigned to punctures. The former factor is irrelevant in our discussion and we neglect it. The latter one is given by the inverse square root of the SCI of \(SU(N)\) free vector multiples. The \(q\)-deformed Yang-Mills partition functions are obtained by removing this factor for each puncture from the SCI expressions and by replacing each vector contribution by 1 which can be interpreted as the integral measure over the fugacity. Since \(\lim_{q \to 0} K(a, q) = 1\), this factor can also be ignored as long as we see the leading order in the \(q\)-expansion of the expressions, which is exactly done in Sec. 2.4 in this paper. We need the concrete expressions of such factors if we compute them at the higher order in the \(q\)-expansion.

1. Formula for no network defect cases

When \(\tilde{C}\) is a genus \(\tilde{g}\) Riemann surface with \(\tilde{n}\) punctures with \(SU(N)\) holonomies, its partition function \(I_{\tilde{C}}(\{z\})\) is given by

\[
I_{\tilde{C}}(\{z\}) = \sum_R (\dim_q R)^{\chi_{\tilde{C}}} \prod_{i=1}^{n} \chi_R(z_i) \tag{2.6}
\]

where \(R\) runs over all unitary irreducible representations of \(SU(N)\), \(\{z\}\) represents the set of holonomies and \(i\) is the index of punctures.

For each summand labelled by \(R\), we can represent the Riemann surface with which \(R\) is assigned. This interpretation will be important later.

2. Gluing

There is a natural operation, gluing, which identifies two holonomies on different punctures and connect them geometrically. On the 4D SCFT side, there are two \(SU(N)\) flavor symmetries which are identified by adding the vector multiplet [73].

If we have two pairs of a Riemann surface with punctures and generic networks on it allowing the case of empty, which are denoted by \((C_A, \Gamma_A)\) and \((C_B, \Gamma_B)\), we can construct new one \((C_{AB}, \Gamma_A \sqcup \Gamma_B)\) by gluing each pair of several punctures. See Fig. 3. Let \(I_{C_{AB}}(\{z\})\) be the expectation values of the 2D topological \(q\)-deformed Yang-Mills theory on \(C\) with a Wilson network defect \(\Gamma\). The corresponding expectation values can be constructed as

\[
I_{C_{AB}, \Gamma_A \sqcup \Gamma_B}(\{a\}, \{b\}) = \prod_i \left( \int [dz_i] \right) I_{C_A, \Gamma_A}(\{z^{-1}\}, \{a\}) I_{C_B, \Gamma_B}(\{z\}, \{b\}) \tag{2.7}
\]

8In the language of class S theory, they are called maximal (or full) punctures.
where $[dz]$ is the Haar measure of $SU(N)$, $\{z\}$ are gauged fugacities and $\{a\}$ and $\{b\}$ are ungauged ones on $C_A$ and $C_B$, respectively. The independence of the order in the glues is obvious.

3. Formula in the presence of loops

According to the result in [24,25], the SCI in the presence of 4D loop operators turns out to coincide with the VEV of Wilson loops in the 2D $q$-deformed Yang-Mills as discussed in [55]. This can be obtained by simply adding the corresponding $SU(N)$ character on gluing as seen soon later.

In this case, $\Gamma$ is a pure loop $\gamma$ along a one cycle in $C$ as depicted in Fig. 4. Let us cut along the Wilson loop labelled by an irreducible representation $R_W$, which is exactly the reversed operation to the previous gluing process, and assume that they are separated after the cut for simplicity. If not, it is enough to replace two expectation values $I_{C_A}$ and $I_{C_B}$ by a single one in (2.8).

The convention about the orientation adopted in this paper differs from [55]. This change is necessary when the surface operators are included because the orientation of the new direction is fixed. See the detail in later Sec. 3.

$$I_{C,\gamma}(\{a\}) = \oint [dz] \chi_{R_W}(z) I_{C_A}(z^{-1}, \{a\}) I_{C_B}(z, \{b\})$$

\[9\text{If not, it is enough to replace two expectation values } I_{C_A} \text{ and } I_{C_B} \text{ by a single one in (2.8).}\]

\[10\text{The convention about the orientation adopted in this paper differs from [55]. This change is necessary when the surface operators are included because the orientation of the new direction is fixed. See the detail in later Sec. 3.}\]
where \( N_{R_B R_W}^{R_A} \) is the Littlewood-Richardson coefficient which counts the multiplicity of the representation \( R_A \) appearing in the tensor product of \( R_B \) and \( R_W \). The recursive applications can give the computations in all the general cases that \( \Gamma \) consists of multiple loops and networks.

If we have two isolated regions across an edge labelled by \( R_W \), to each summand in (2.9), we can assign irreducible representations \( R_A \) and \( R_B \) to \( C_A \) and \( C_B \), respectively. See Fig.5. The summand vanishes unless \( N_{R_B R_W}^{R_A} \neq 0 \) and then we have the constraint \( R_B \in R_A \otimes R_W \) meaning that the irreducible decomposition of \( R_A \otimes R_B \) includes \( R_W \).

In particular, in our convention, the charge on each edge is a fundamental representation \( \wedge^a \Box \) and the above constraint on \( R_A \) and \( R_B \) becomes powerful, which will turn out to be useful in the analysis in Sec. 2.3.1.

Let us make a few remarks. When \( Z_R \) denotes the center charge of \( R \), this constraint leads to \( Z_{R_B} + a = Z_{R_A} \mod N \) when \( R_W = \wedge^a \Box \). This implies that the expectation values vanish unless all the intersection numbers of any one cycles with the Wilson networks vanish. For example, in the case that \( C \) is an once-punctured torus, the expectation value of the fundamental Wilson loop along \( \alpha \)-cycle vanishes. In particular, when the puncture is special called simple or minimum, this introduces a Wilson loop in \( \Box \) in some duality frames on the 4D \( SU(N) \) gauge theory side but it is localized at a point in \( S^3 \) which is a compact space. Its center charge is not screened by the dynamical matter because all belongs to the adjoint representations and this theory is anomalous because there is a single source with a non-trivial Abelian charge on the compact space \([74,75]\).

4. Partially Higgsing/closing

If we have global \( SU(N) \) symmetry in 4D \( \mathcal{N}=2 \) SCFTs, there are BPS primary operators in the same supermultiplet as the flavor current belongs to. They are the triplet of \( SU(2)_R \) R-symmetry and the adjoint representation of \( SU(N) \) global symmetry. By giving a nilpotent VEV to the highest weight of those operators at UV point, we have another SCFTs in the IR. This is called partially Higgsing/closure operation \([72,76]\). The nilpotent orbit of \( SL(N,\mathbb{C}) \) can be always uniquely mapped to the Jordan normal forms \( J_Y = \oplus_i J_{n_i} \) whose all eigenvalues vanish and they are classified by the partition.
$Y = [n_1, n_2, \ldots, n_d]$ of $N$. Now that $SU(2)_R \times SU(N)$ global symmetry is spontaneously broken into a subgroup $U(1) \times G_Y$. In particular, this $U(1)$ is generated by

$$I^3_{IR} := I^3_{UV} \otimes 1 - 1 \otimes \frac{1}{2} \rho^3_Y$$  \hspace{1cm} (2.10)$$

where $\rho_Y$ is the unique embedding homomorphism from $\mathfrak{su}(2)$ into $\mathfrak{su}(N)$ satisfying $J_Y = \rho_Y \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, $\rho^3_Y := \rho_Y \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ and $I^3_{UV}$ is a diagonal $R$-symmetry generator of $SU(2)_R$. This $R$-symmetry generator in new IR SCFT is enhanced to $SU(2)_{IR}$ and the SCI can be also defined there. The RG invariance implies

$$q^{-I^3_{IR} a_Y} = q^{-I^3_{UV} a}$$  \hspace{1cm} (2.11)$$

where $a_Y$ is the fugacities in the Cartan subgroup of $G_Y$. In conclusion, the partially closing operation on each maximal puncture is equivalent to the following replacement $^{15,57,72}$:

$$a \longrightarrow q^\frac{\rho^3_Y}{2} a_Y.$$  \hspace{1cm} (2.12)$$

As for the notation used here, see the beginning of Sec. 3. Hereafter, we use the transpose of $Y$ to specify the type of punctures. For example, $[N]$ represents the full (maximal) puncture and $[2, 1^{N-2}]$ does the simple (minimum) puncture.

### 2.3 A proposal for closed Wilson networks

At this stage, any expectation value of any network defect is a function of holonomies for $SU(N)$ global symmetries on each maximal puncture. Recall that we can always take each $SU(N)$ holonomy in the maximal torus $T^{N-1}$ which is a $N$-tuple of $U(1)$ holonomies $a_1, a_2, \ldots, a_N$ with the constraint $a_1 a_2 \cdots a_N = 1$ but there left the ambiguity of its permutations. The invariance under the permutations (or conjugacy actions of $SU(N)$) implies that the expectation values can be expanded with the characters of $SU(N)$ again and written as

$$I^\mathcal{C,}_{I}(\{a\}) = \sum_{\{R_p\}} B^\mathcal{C,}_{I}(\{R_p\}) \prod_{p=1}^{n} \chi_{R_p}(a_i).$$  \hspace{1cm} (2.13)$$

where $\{R_p\}$ means that each $R_p$ runs over the set of the unitary irreducible representations of $SU(N)$. We also use the same $n$ as before for the number of maximal punctures on $\mathcal{C}$. As we have seen in (2.6), for any 2D $q$-deformed Yang-Mills partition functions without defects, the coefficient $B$ in the character expansion is diagonal in $\{R_i\}$ and each component is given by $(\dim_q R)^{\chi_C}$. In other words,

$$B_{I(R)} = (\dim_q R)^{\chi_C} \prod_{p=1}^{n} \delta_{R_p,R}$$  \hspace{1cm} (2.14)$$
where $\delta_{R_p, R}$ gives 1 when $R_p = R$ and 0 otherwise.

Now our goal is to give the procedure for computations of $B_{\Gamma;\{R\}}$. For that purpose, let us interpret this as a Boltzmann factor of a statistical mechanics on a lattice system defined by following three steps:

1. Make a dual ideal triangulation

The Riemann surface $\tilde{C}$ decomposes into the several components by removing the locus of network defects $\tilde{\Gamma}$. The previous construction via fat graphs ensures the natural one-to-one correspondence between the components of regions and the boundaries/punctures. Now consider the dual quiver on $\tilde{C}$ associated with the network $\tilde{\Gamma}$. This is obtained when each region or puncture and network’s edge are mapped into a vertex and an arrow with the charge, respectively. At this stage, the summation in (2.13) says that there lives a discrete but infinite physical degree of freedom labelled by the irreducible representations of $SU(N)$ or the dominant weights on each vertex. Any junction is mapped into a triangle because of the trivalence property of the network. Note that similar operations already appeared many times in various contexts, see [2, 39] for example. So we have (ideal) triangulations with a charge on each edge, of $\tilde{C}$. Two or three vertices of a triangle are allowed to be common at this stage but, in Sec. 2.3.1, we will see that we can ignore such triangulations. Notice also that the number of triangles is given by $-2\chi_{\tilde{C}}$ on recalling footnote 7.

2. Consider the allowed configurations of dominant weights

The whole configuration space is the set of all maps from each quiver vertex to an irreducible representation or a dominant weight. However, for many configurations, $B_{\Gamma;\{R\}}$ in (2.13) vanishes as we will discuss in 2.3.1 and we can restrict the range of the summation to the non-vanishing configurations.

3. Give the Boltzmann factor for each configuration

As with the ordinary statistical mechanics such as Ising models, we assume the Boltzmann factor of a given configuration is the product of local Boltzmann factors over all the triangles. In other words, the local Boltzmann factor denoted $B_{\lambda_A, \lambda_B, \lambda_C}^{\triangle}$ is a function on triples of dominant weights living on three vertices of a single triangle $\triangle$ and the total Boltzmann factor is given by

$$B_{\Gamma;\{R\}} = \prod_{\triangle} B_{\lambda_{\triangle,A}, \lambda_{\triangle,B}, \lambda_{\triangle,C}}^{\triangle} \quad (2.15)$$

where $\triangle$ runs over all the triangles on the ideal triangulation of $\tilde{C}$. The concrete formula of $B_{\lambda_A, \lambda_B, \lambda_C}^{\triangle}$ will be given as (2.20) in Sec. 2.3.2.

2.3.1 Selection rules on dominant weights

Here we exhaust all the configurations whose Boltzmann factors are non-vanishing. The strategy is same as that used in [55].
Let us consider \((a_{AB}, a_{BC}, a_{CA})\)-junction and three regions around it as shown in Fig.6. There are still two types of junctions, inflowing one and outgoing one but hereafter we focus on outflowing one only because the final expressions for \(B^\triangle\) are same for both types. Let three dominant weights living on its vertices be \(\lambda_A, \lambda_B\) and \(\lambda_C\) and define \(\lambda_{XY} := \lambda_X - \lambda_Y\) for \(X, Y \in \{A, B, C\}\). The gluing procedure stated in Sec. 2.2 tells that \(R(\lambda_Y) \otimes \wedge^{a_{XY}} \square\) contains \(R(\lambda_X)\) for \((X, Y) = (A, B), (B, C)\) and \((C, A)\). This statement equals to \(\lambda_{XY} \in \Pi(\wedge^{a_{XY}} \square)\) where \(\Pi(R)\) is a set of all weights of the highest representation \(R\). Then there is a unique subset \(E_{XY}\) of \(\{1, 2, \ldots, N\}\) consisting of \(a_{XY}\) elements such that \(\lambda_{XY} = \sum_{s \in E_{XY}} h_s\). The cycle condition \(\lambda_{AB} + \lambda_{BC} + \lambda_{CA} = 0\) means that \(E_{AB}, E_{BC}\) and \(E_{CA}\) has no common element and \(E_{AB} \cup E_{BC} \cup E_{CA} = \{1, 2, \ldots, N\}\). In conclusion, allowed configurations have several sectors determined by the choice of \(E_{AB}, E_{BC}\) and \(E_{CA}\) which is a partition of \(\{1, 2, \ldots, N\}\) into three sets. Note that there are \(\frac{N!}{a_{AB}! a_{BC}! a_{CA}!}\) sectors for single junction. And in each sector, there is a summation over \(\lambda_A\) for example, \(^{12}\) with a constraint that all \(\lambda_A, \lambda_B\) and \(\lambda_C\) are dominant weights. \(^{13}\)

Notice also that two adjacent vertices must have different center charges as we have seen at part 3 in Sec. 2.2 and we can say that there is no edge whose starting vertex and terminating one are common.

### 2.3.2 Conjectural formula for the local Boltzmann factor

The last task is to show the way to get the local Boltzmann factor for any allowed triple of dominant weights \(\lambda_A, \lambda_B\) and \(\lambda_C\).

Before going to the final result, we must prepare some tools to express it simply. First of all, we introduce a mathematical object playing central roles in our computations. This is just an assembly of integers designated by two labels \(h\) and \(\alpha = \alpha_h\). \(h\) runs over

---

\(^{12}\)Of course, it is possible to choose \(\lambda_B\) or \(\lambda_C\) instead. In all cases, the other two dominant weights are determined if we specify the sector at first.

\(^{13}\)In other words, this is just summation over \(\lambda_A\) and pairs of \(\lambda_B - \lambda_A\) and \(\lambda_C - \lambda_A\). The later two pairs label the sectors.
1, 2, ..., \(N - 1\) and \(\alpha\) does over 1, 2, ..., \(N - h\) for each \(h\). Therefore, this object consists of \(\frac{1}{2}N(N - 1)\) integers. We call such object “pyramid” hereafter. See Fig. 7.

In particular we have a natural map defined just below which sends a weight \(\lambda = [\lambda_1, \lambda_2, \ldots, \lambda_{N - 1}]\) where \(\lambda = \sum_{\beta=1}^{N} \lambda_{\beta} \omega_{\beta}\) to a pyramid and denote the image by \(\hat{\lambda}\) or \(\hat{\lambda}_{h;\alpha}\).

The definition of the map is

\[
\hat{\lambda}_{h;\alpha} := \sum_{\beta=\alpha}^{\alpha+h-1} \lambda_{\beta}.
\]

Hereafter, we permit an abuse of notation. We use the same symbol \(\hat{\lambda}\) for the pyramids not in the image of this inclusion map too. In such cases, \(\hat{\lambda}\) is to be considered as a single symbol as a whole and \(\lambda\) is meaningless.

Next, we define majority function \(m_j\) for three variables :

\[
m_j(a, b, c) := \begin{cases} a & b = a \text{ or } c = a \\ b & a = b \text{ or } c = b \\ c & a = c \text{ or } b = c \end{cases}.
\]

Since, hereafter, there appears no case that all variables are distinct, this definition is well-defined in our usage. In particular, we extend this to the case that the variables are pyramids as follows :

\[
m_j(\hat{\lambda}_A, \hat{\lambda}_B, \hat{\lambda}_C) := \{m_j((\hat{\lambda}_A)_{h;\alpha}, (\hat{\lambda}_B)_{h;\alpha}, (\hat{\lambda}_C)_{h;\alpha})\}_{h;\alpha}.
\]

Finally, we define \(q\)-dimension function \(D\) :

\[
D[\hat{\lambda}] := \prod_{h=1}^{N-1} \prod_{\alpha=1}^{N-h} \frac{[\hat{\lambda}]_{h;\alpha} + h}_{[h]_q}.
\]

Now that we get all necessary tools, let us write down the local Boltzmann factors for three dominant weights \(\lambda_A, \lambda_B\) and \(\lambda_C\) living on its vertices. This is expressed as

\[
B_{\lambda_A, \lambda_B, \lambda_C}^{\Delta} = \frac{1}{D[m_j(\hat{\lambda}_A, \hat{\lambda}_B, \hat{\lambda}_C)]^2}.
\]
Based on this proposal, we derive several skein relations in App. [B] which provides a (mathematical) evidence that this proposal works well. As we will see in the following examples, an implication of global symmetry enhancements also supports the validity of the above formula.

2.4 Concrete computations

In this section, we see three examples: $T_3$-theory, $T_4$-theory including a Higgsed theory of it, and $T_{4[N]}$-theories for general $N$. $T_N$-theory is a SCFT in the case that $C$ is a two-sphere with three maximal punctures labelled by $[N]$. $T_{4[N]}$-theory corresponds to a two-sphere with four maximal punctures. In the first two cases, namely, $T_3$ and $T_4$-theories, these theories are Argyres-Seiberg dual theories to some theories and their Lagrangians are unknown yet [77,78] although, for the $T_3$-theory, there is an interesting proposal that an $\mathcal{N}=1$ Lagrangian theory flows in the IR to that theory [79]. There we consider elementary defects as shown in Fig. 8. They were discussed explicitly at first in [39] and shown to be elementary generators of the line operator algebra in [41]. They are called pants networks there. In the last example, we consider the two loops wrapping different one cycles as shown in Fig. 9.

$T_3$ theory

In this theory, we can see that the above conjectural procedure exactly reproduces the previous result computed in [55]. There is just only pants network defect in $T_3$ theory up to charge conjugate operation, namely, $a_{AB} = a_{BC} = a_{CA} = 1$. Using the cyclic symmetry $A \to B \to C \to A$, we can take $E_{BC} = \{3\}$ without loss of generality and write the Dynkin labels of $\lambda_C$ as $[n, m]$. Note that $\lambda_B = [n, m-1]$. Then there are two sectors: $(E_{AB}, E_{CA}) = ([1], [2])$ and $([2], [1])$. The former and latter give $\lambda_A = [n+1, m-1]$ and $[n-1, m]$, respectively, and the local Boltzmann factors are given by

$$B^\Delta = \frac{2}{[n+1][m][n+m+2]} \quad \text{for } ([n,m],[n,m-1],[n+1,m-1])$$

(2.21)
\[ B^{\Delta} = \frac{[2]}{[n][m+1][n+m+1]} \quad \text{for } ([n,m],[n,m-1],[n-1,m]). \] (2.22)

**T\textsubscript{4} theory and T\textsubscript{[4],[4],[2]} theory**

There is only \((2,1,1)\)-junction and, therefore, there are three types of pants networks. However, their expectation values are exchanged under the cyclic permutation \(a_{AB} \rightarrow a_{BC} \rightarrow a_{CA} \rightarrow a_{AB}\) and we can set \(|E_{AB}| = 2\) without loss of generality. There are 12 distinct sectors for \((2,1,1)\)-junction. If we expand the \(q\)-deformed Yang-Mills expectation values in terms of \(q\), this is given by

\[
q^{1/2} \chi_\Box(a) \chi_\Box(b) + q \left[ \chi_\Box(b) \chi_\Box(c) + \chi_\Box(a) \chi_\Box(c) \right] + q^{3/2} \chi_\Box(a) \chi_\Box(b) \chi_\Box(c) + q^2 \left[ \chi_{\text{Adj}}(a) \chi_\Box(b) \chi_\Box(c) + \chi_\Box(a) \chi_\Box(b) \chi_{\text{Adj}}(c) \right] + O(q^{5/2}) \quad (2.23)
\]

and the Schur index can be obtained by multiplying a prefactor \((q^2; q)\,\infty(q^3; q)\,\infty(q^4; q)\,\infty\)

\[
\prod_{x=a,b,c} \frac{q}{1-q} \chi_{\text{Adj}}(x) \quad \text{where } (x; q) := \prod_{i=0}^{\infty} (1 - xq^i) \quad \text{and} \quad \prod_{\alpha \in \Pi(\text{Adj})} \frac{1}{(q^{x^\alpha}; q)\,\infty}\quad [14]
\]

Next, let us consider \(T_{[4],[4],[2]}\)-theory where \(C\) is a two-sphere with two maximal punctures and one \([2,2]\)-type puncture. The reason why we focus on this case is that this theory enjoys the global symmetry enhancement from the manifest global symmetry \(SU(4) \times SU(4) \times SU(2)\) into \(E_7\) global symmetry \([7],[8]\).

On performing partially closing operations and the \(q\)-expansion, we must take account of the higher powers of \(q\) in the above analysis because \(\chi_{\text{R}}^{SU(4)}(x)\) is a series of \(q^{1/2}\) including negative powers, where \(x\) is a UV holonomy associated with the \([2,2]\)-type puncture. See part.4 in Sec. 2.2 as to the partially closing operation. By taking it into considerations, it turns out that there are following four possible configurations contributing to the lowest order of \(q\) : \( (R_A, R_B, R_C) = 1. (\Box, \phi), 2. (\phi, \Box, \Box), 3. (\Box, \Box, \phi) \) and \( 4. (\Box, \Box, \Box) \). In conclusion, we have

\[
I(a, b, c') = q^{1/2} \chi_{\Box}^{SU(4)}(a) \chi_{\Box}^{SU(2)}(b') + O(q^{3/2}) \quad (2.24)
\]

\[
I(a', b, c) = \chi_{\Box}^{SU(4)}(b) \chi_{\Box}^{SU(2)}(a') + O(q) \quad (2.25)
\]

\[
I(a, b', c) = \chi_{\Box}^{SU(4)}(a) \chi_{\Box}^{SU(2)}(b') + \chi_{\Box}^{SU(4)}(c) + O(q) \quad (2.26)
\]

where \(x'\) for \(x = a, b\) and \(c\) is related to \(x\) by \(x = (q^{1/2}x', q^{-1/2}x', q^{1/2}x'-1, q^{-1/2}x'-1)\). Recalling the fact that the Coulomb branch complex dimension of \(T_{[4],[4],[2]}\)-theory is 1, this is consistent with this result that there is only one elementary network reflecting the global \(E_7\) symmetry.

\[\text{For generic punctures, this prefactor is slightly changed because we must remove the NG modes associated with the symmetry breaking \([16],[72],[80]\).}\]
Figure 9: Two dual intersecting loops. If the upper punctures are simple / minimum type \([2,1^{N-2}]\), the red loop corresponds to the fundamental Wilson loop and the green one does to some ‘t Hooft loop.

**Dual intersecting loops in** \(T_{4\text{fulls}}\)

Let us consider the case with \(a = b = 1\) in Fig. 9. This theory reduces into \(SU(N)\) superconformal QCD (SCQCD) on partially closing two of four punctures into the simple \([2,1^{N-2}]\)-type punctures. On that theory, these two loops correspond to the ordinary fundamental Wilson loop and some ‘t Hooft loop.

Using the crossing resolutions, this decomposes into four components. By evaluating each component and then by summing them up, we have the following results for the whole Boltzmann factor (the definition of \(E_{XY}\) is given in Sec. 2.3.1):

1. case \(E_{BA} = E_{DA} = E_{CB} = E_{CD} = \{\ell\}\) for \(\ell \in \{1,2,\ldots,N\}\)

\[
B_{\beta\alpha;\{\lambda\}} = \frac{1}{D[\lambda_B]^2} \tag{2.27}
\]

where \(\lambda_B = \lambda_D\).

2. case \(E_{BA} = E_{DA} = \{\ell\}\) and \(E_{CB} = E_{CD} = \{k\}\) for \(\ell \neq k \in \{1,2,\ldots,N\}\)

\[
B_{\beta\alpha;\{\lambda\}} = \frac{1}{D[\lambda_B]^2[\kappa + \sigma_0]^2} \tag{2.28}
\]

where \(h_0 := |k - \ell|\), \(\alpha_0 := \min(k,\ell)\), \(\sigma_0 := \text{sgn}(\ell - k)\) and \(\kappa := (\lambda_B)_{h_0;\alpha_0} + h_0\). Note also \(\lambda_B = \lambda_D\).

3. case \(E_{CD} = E_{BA} = \{\ell\}\) and \(E_{DA} = E_{CB} = \{k\}\) for \(\ell \neq k \in \{1,2,\ldots,N\}\)

\[
B_{\beta\alpha;\{\lambda\}} = \frac{1}{D[\lambda_B + f(\{\ell\},\{k\})]D[\lambda_D + \hat{f}(\{k\},\{\ell\})]} \tag{2.29}
\]

where \(\lambda_B - h_k = \lambda_D - h_\ell\) and see App. A as to \(\hat{f}(\{k\},\{\ell\})\).

\[\text{At least, its ‘t Hooft’s topological charge is neutral. It is an interesting problem to identify what line defect on the 4D SCQCD precisely corresponds to the given loops on the 2D geometry side.}\]
It is possible to rewrite the above expression into

\[ B_{\beta\alpha;\{\lambda\}} = \frac{1}{D[\hat{\lambda}_B]D[\hat{\lambda}_D]} \frac{[\kappa]_q[\kappa + 2\sigma_0]_q}{[\kappa + \sigma_0]_q^2}. \] (2.30)

There is a relation \( \kappa = (\hat{\lambda}_B)_{h:\alpha_0} + h_0 = (\hat{\lambda}_D)_{h:\alpha_0} + h_0 - 2\sigma_0. \)

Note that the ordering of additions of the two loops is irrelevant in q-deformed Yang-Mills theory (not so in the Liouville-Toda CFT case) and they commutes each other. We can naturally understand this if we put them in three dimensional space \( C \times S^1 \) as discussed in Sec. 3.

2.5 A remark on \( \mathcal{R} \)-matrix

As we see in the last example in the previous section, it is possible to compute the local Boltzmann factor for a single crossing or on the dual rectangle. See Fig. 10. Roughly speaking, the factors are the square root of the previous results, but there appear some additional powers of \( q \). The factors can be given as follows:

1. case \( E_{BA} = E_{DA} = E_{CB} = E_{CD} = \{\ell\} \)

\[ B_{\square}^{\text{crossing}} = (-q^{1/2})^\frac{1}{N} \frac{-q^{-1/2}}{D[\hat{\lambda}_B]} \] (2.31)

where \( \lambda_B = \lambda_D \) again.

2. case \( E_{BA} = E_{DA} = \{\ell\} \) and \( E_{CB} = E_{CD} = \{k\} \) for \( \ell \neq k \)

\[ B_{\square}^{\text{crossing}} = (-q^{1/2})^\frac{1}{N} \frac{-\sigma_0 q^{-\sigma_0 \kappa - 1}}{D[\hat{\lambda}_B][\kappa + \sigma_0]_q} \] (2.32)

where we use the same \( \kappa \) and \( \sigma_0 \) as before. Note also \( \lambda_B = \lambda_D \) again.
3. case $E_{CD} = E_{BA} = \{\ell\}$ and $E_{DA} = E_{CB} = \{k\}$ for $\ell \neq k$

$$B_{\text{crossing}} = \left(-q^{1/2}\right)^{1/2} D^{(\lambda_B)} D^{(\lambda_D)} \frac{[\kappa]_{q}^{1/2} [\kappa + 2\sigma_0]_{q}^{1/2}}{[\kappa + \sigma_0]_{q}}. \quad (2.33)$$

The other crossing is obtained by just replacing $q$ by $q^{-1}$. All the above results can have similar structures to those for triangles.

It is a very interesting problem to analyze all types of crossings or to relate the above local Boltzmann factors to the known models such as face or (R)SOS models [82] [86].

3 Composite surface-line systems

As explained in the introduction, in the 2D system, the geometric counterparts of 4D line operators and 4D surface operators are networks and punctures, respectively. As long as we treat either only surface operators or only line operators, the projection onto $C$ is natural to discuss the 4D physics. However, if we have line defects bounded on 2D surface defects, it is not unique picture and there appears the new direction which line defects are localized in but surface defects extend along.

In Sec. 3.1, we review several basic facts needed later. Next, we take a look at the geometrical configurations of two types of defects in Sec. 3.2. In Sec. 3.3, we discuss the skein relations including fully degenerate punctures. First, by introducing new topological moves, we derive such skein relations in some simple cases. Then, in the last Sec. 3.4, we rederive more general skein relations assuming the projection invariance.

3.1 Brief review

Notation

For a maximal torus element $a \in \mathbb{T}^{N-1}$ of $SU(N)$ and a weight vector $\lambda \in \Lambda_{\text{wt}} \simeq \mathbb{Z}^{N-1}$, we introduce a symbol $a^\lambda := (a_1^\lambda, a_2^\lambda, \ldots, a_N^\lambda)$ where $\lambda_i := (\lambda, h_i) \ i = 1, 2, \ldots, N$. 16

$\rho$ denotes the Weyl vector, which is defined as $\sum_{a=1}^{N-1} \omega_a$. $C_2(R)$ is the quadratic Casimir defined as $\langle \lambda, \lambda + 2\rho \rangle$ which is normalized as $C_2(\square) = N - \frac{1}{N}$. We also introduce a symbol $\sigma_R = (-1)^{|R|(|N-1)|}$ where $|R|$ is the number of the boxes in the Young diagram corresponding to the irreducible representation $R$.

To avoid the appearance of numerical complex factors, through this section, we use the Liouville-Toda convention, which is the same as that used in Sec.3 in [55]. See the footnote 5 as to this point.

16Note that we keep the symbol $\lambda_\alpha$ as the Dynkin labels which are coefficients of $\omega_\alpha$ of the highest weight. See App. A as for Lie algebra notations. The inner product $\langle , \rangle$ is also defined there.
Skein relations

We show two necessary skein relations in this section. See [55] for more relations. One type is crossing resolutions already shown in the previous section.

\[
q^{\frac{c}{N}} \sum_{i=0}^{c} q^{-i} a - b - i = a + b - i
\]

where \(c := \min(a, b, N - a, N - b)\). Hereafter, using (2.1), we only consider the case \(a, b \leq \frac{N}{2}\) for simplicity. Note that each part of the right hand has a relation like

\[
q^{\frac{c}{N}} \sum_{i=0}^{c} q^{-i} a - b - i = a + b - i
\]

The other one is Reidemeister move I:

\[
\sigma_R q^{-C_2(R)} = \sigma_R q^{C_2(R)}
\]

where \(R\) can be any irreducible representation other than fundamental representations \(\wedge^a\).

Surface defect

It was discussed in [57] that the SCIs in the presence of surface defects can be physically obtained by coupling a free hypermultiplet carrying \(U(1)\) baryon symmetry to the original theory at UV and by taking the IR limit of that theory after giving variant VEVs to Higgs branch operators. At the mathematical level, this corresponds to taking the residues at a pole in the fugacity complex planes, associated with the surface operator’s charges and finally results in a difference operator acting on the flavor fugacities of the original theory.

The above procedure is expected to reproduce in the IR the same defects as those from codimension four defects in 6D \(\mathcal{N}=(2,0)\) SCFTs and, in fact, this was checked in [32] by comparing these results with 4D SCIs coupled to the elliptic genera of the 2D \(\mathcal{N}=(2,2)\) theories living on the surface defects. The difference operators in the Schur limit actually
form the representation ring of \( su(N) \) because the codimension four defects are labelled by representations of \( su(N) \) \[58,59\].

According to \[57–59\], we rewrite the difference operator for the surface defect labelled by an irreducible representation \( S \) as

\[
\mathcal{G}_S = \left( \sqrt{I_{\text{vector}}(a)} \right) \cdot \left[ \sum_{\lambda \in \Pi(S)} q^{-N(\lambda,\lambda)} a^{N\lambda} \hat{\Delta}_{-\lambda} \right] \cdot \left( \sqrt{I_{\text{vector}}(a)} \right)^{-1} \tag{3.4}
\]

\[
= \left( \sqrt{\Delta_{\text{Haar}}(a)} \right)^{-1} \left[ \sum_{\lambda \in \Pi(S)} \hat{\Delta}_{-\lambda} \right] \cdot \left( \sqrt{\Delta_{\text{Haar}}(a)} \right) \tag{3.5}
\]

where we have renormalized so that they form the representation ring of \( su(N) \) exactly,

\[
I_{\text{vector}}(a) \text{ is the SCI contribution from the vector multiplet whose concrete expression does not matter in this paper, } \Delta_{\text{Haar}}(a) \text{ is the Haar measure of } SU(N) \text{ and } \hat{\Delta}_{-\lambda} \text{ acts on a holonomy } a \text{ by } q^{-2\lambda}a. \] The characters \( \chi_R(a) \) are common eigenfunctions of these operators for any \( S \) and their eigenvalues are given by

\[
\hat{\mathcal{E}}^{(S)}_R = \chi_S(q^{-2(\rho+\lambda_R)}) = \frac{\dim_q S}{\dim_q R} \chi_R(q^{-2(\rho+\lambda_S)}). \tag{3.6}
\]

Finally, we remark on the mathematical relation between the codimension four defects and the codimension two defects \[47\]. In the Liouville-Toda CFT set-up, the general vertex operator is given by \( V_\alpha(z) = e^{\langle \alpha, \phi(z) \rangle} \) where \( \alpha \) is a vector in \( \mathfrak{h}^\vee \) which is the dual to Cartan subalgebra, \( z \in C \) and \( \phi(z) \) is the Liouville-Toda scalar field. This corresponds to the general codimension two defect ([\( N \)] type or maximal puncture) when \( \alpha - (b + 1/b)\rho \in i\mathbb{R}^{N-1} \simeq \mathfrak{h}^\vee \). On the other hand, the codimension four defect labelled by a \( su(N) \) irreducible representation \( S \) is obtained by taking the limit \( \alpha \to -b\lambda_S \) or \(-1/b\lambda_S\). \[17\] The vertex operator in this limit is called fully degenerate and we also refer to the corresponding punctures as fully degenerate punctures which exactly represent the 4D surface defects.

In the 2D \( q \)-deformed Yang-Mills theory, the procedure similar to the above one is given as

\[
\lim_{a \to q^{-\rho-\lambda}} \frac{\chi_R(a)}{\dim_q R} = \frac{\hat{\mathcal{E}}^{(S)}_R}{\dim_q S} \tag{3.7}
\]

where the denominator on the right hand side is just simply the normalization factor of the surface defect. In our normalization, the surface defects exactly reproduce the \( su(N) \) representation ring:

\[
\hat{\mathcal{G}}_{S_1} \circ \hat{\mathcal{G}}_{S_2} = \sum_{S_3} N_{S_1S_2} S_3 \hat{\mathcal{G}}_{S_3} \quad \text{or} \quad \hat{\mathcal{E}}^{(S_1)}_R \hat{\mathcal{E}}^{(S_2)}_R = \sum_{S_3} N_{S_1S_2} S_3 \hat{\mathcal{E}}^{(S_3)}_R. \tag{3.8}
\]

\[17\] The two limits correspond to two types of configurations of surface defects in \( S_b^4 \). See the next subsection \[3.2\].
3.2 Geometrical configurations

Originally, the bulk geometry of 6D $\mathcal{N}=(2,0)$ SCFT is $S^3 \times S^1_E \times C$. Both surface defects and line defects in 4D wrap $S^1_E$. After the $S^1_E$ reduction, the geometry is the product of $C$ and a $S^1_H$-fibration over $S^2$ in our viewpoint. $S^1_H$ is a Hopf fiber which is the support of surface defects in 4D. On the other hand, line defects in 4D are networks on $C$. Therefore, both types of defects are knots with junction in the fiber geometry $S^1_H \times C =: M$ and localized at the same point in base geometry $S^2$. In the following discussion, we regard $S^1_H$ as an interval $I_H$ whose two end points are identified. Then let $C_{in}$ and $C_{out}$ denote two boundaries of $I_H \times C$. We interpret the surface defects as a defect running from a point in $C_{in}$ to the same point in $C_{out}$ along the $I_H$-direction.

Note that if we consider a 6D $\mathcal{N}=(2,0)$ SCFT on $S^4 \times C$, a similar argument holds true. This is because OPEs of two BPS defects are expected to be determined locally and independent from the global background geometry. Concretely, a surface defect extends along a $S^2 = \{(z, w = 0, x) \in \mathbb{C} \times \mathbb{R} \mid b^2|z|^2 + x^5 = 1\}$ in $S^4 = \{(z, w, x) \in \mathbb{C} \times \mathbb{R} \mid b^2|z|^2 + b^{-2}|w|^2 + x^5 = 1\}$ and some line defects live on $S^1 = \{(z, w = 0, x_5 = x_*) \in \mathbb{C} \times \mathbb{R}\}$ where $x_*$ is an arbitrary constant satisfying $|x_*| < 1$. Since only the local geometry around the defect locus is relevant, instead of $S^1_H$, we take the new direction as the $x_5$ direction (open interval) in this case. Therefore, it is expected that the skein relations discussed in Sec. 3.3 are also applied to the Liouville-Toda CFTs and we can check, in several examples, the claim that they are common in both systems. The relation between $q$ and $b$ is given in [24] or [55] as $q = e^{i\pi b^2}$.

The phenomenon inherent in the $S^4_b$ case is that there simultaneously exist two types of line operators and, in such a case, it seems to be necessary to treat them in the full five dimensional geometry rather than three dimensional one. Notice also that there are two distinct origins of the non-commutativity of line operators correspondingly. One comes from the Poynting vector in the bulk generated by line’s charges as discussed in [26,69] and this classical picture also may be valid in the Schur index case. The other interpretation is similar but different. There, both line operators cannot be genuine line operators and either should be the boundary of an open surface operator. Then, two operators have some contact interactions under the exchange of their ordering in the 4D bulk [87,89].

3.3 Skein relations with fully degenerate punctures

At first, we use the same projection of $M$ onto the 2D plane as before. This is the projection onto $C$ which we call “$C$-projection”.

If the 4D surface defects are topological in $M$, by deforming its orbit in $M$, we expect the following relation:

$$S \bullet = S \circ \sigma_s q^{C_2(S)} S \circ \sigma_s q^{-C_2(S)} S \circ . \quad (3.9)$$

\[18\text{There are at least two kinds of surface defects when line defects are absent. The other one is obtained by exchanging two SCI fugacities $p$ and $q$ as seen in [57].}]

22
Here we must take the framing factor appearing in R-move I \((3.3)\) into consideration.

Let a white dot (a circle) and a black one (a filled circle) in the \(C\)-projection plane represent each intersection point of a surface defect with \(C_{in}\) and \(C_{out}\), respectively. Then new moves appear:

\[
\begin{align*}
S & \quad R \\
\text{S} & \quad \text{S} \\
\text{S} & \quad \text{S}
\end{align*}
\]

\[
S \quad R = S \quad R, \quad S \quad R = S \quad R. \quad (3.10)
\]

On the left hand side, a line labelled by \(S\) stems from the white dot in \(M\) and, on the right hand side, a line by \(S\) goes into the black dot in \(M\). We call this relation Reidemeister move V (R-move V). In particular, because two types of dots are identified in \(S^1_H\), they coincide in \(C\)-projection and we have

\[
R = R. \quad (3.11)
\]

We refer to the edges with dots on it as “punctured edges”. Be aware that the punctured edges are just open lines in the three dimensional space \(M\). A view from the right hand towards the left hand is shown in Fig. 11. See also Sec. 3.4 for the detail.

\[
\begin{align*}
S & \quad \text{C}_{out} \\
\text{S} & \quad \text{S} \\
\text{S} & \quad \text{S}
\end{align*}
\]

\[
(3.12)
\]

Figure 11: A punctured edge labelled by \(S\) in the left can be depicted as the right in the projection from \(M\) onto other 2D plane extending along the Hopf fiber direction.

What we are interested in is the situation where a line in \(C\) passes near a fully degenerate puncture. The above relation \((3.11)\) leads to

\[
S \quad R = S \quad R. \quad (3.13)
\]
and now we can apply the crossing resolutions (3.1) to the network representation on the right hand.\[19\]

**Special case**

Let us take $S$ and $R$ as $\square$ (or 1) and $\wedge^k\square$ (or $k$), respectively. There are two ways to do the calculations:

\[
\begin{align*}
\begin{array}{c}
1 \circ \quad = \sigma_{\square} q^{C_2(\square)} \\
\end{array}
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
1 \circ \quad = q^{\frac{2k}{N}} \\
\end{array}
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
1 \circ \quad = (-1)^k q^{ \frac{2k-1}{N} + k-1 (q - q^{-1})} \\
\end{array}
\end{align*}
\]

On the other hand,

\[
\begin{align*}
\begin{array}{c}
1 \circ \quad = \sigma_{\square} q^{-C_2(\square)} \\
\end{array}
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
1 \circ \quad = q^{\frac{2k}{N} - 2} \\
\end{array}
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
1 \circ \quad = (-1)^{k-1} q^{- \frac{2k+1}{N} + k-1 - N (q - q^{-1})} \\
\end{array}
\end{align*}
\]

Comparing both expressions, we have

\[
\begin{align*}
\begin{array}{c}
\circ 1 \quad = (-1)^{k-N-1} q^{ \frac{1}{N} + k-1} \\
\end{array}
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
\circ 1 \quad = (-1)^{k+1} q^{- \frac{1}{N}} \\
\end{array}
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
\circ 1 \quad = q^{- \frac{k}{N}} \\
\end{array}
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
\circ 1 \quad + q^{- \frac{k}{N}} \\
\end{array}
\end{align*}
\]

\[19\text{Another more useful way to derive the same result is to separate the locations of ingoing and outgoing punctures (white and black dots) in $C$ firstly, to apply the skein relations secondly and to merge them again finally.}\]
In the same way, we also have

\[
1 \otimes 1 = q^{k/N} \begin{bmatrix}
1 & 1 & 1 \\
-1 & k & -1 \\
1 & k & 1
\end{bmatrix}.
\] (3.18)

In the simplest case \( N = 2 \) and \( k = 1 \) which do not need any junctions and arrows on edges, this becomes simpler as follows:

\[
1 \otimes 1 = q^{-\frac{1}{2}} 1 + q^{\frac{1}{2}} 1
\] (3.19)

and the other relation can be obtained by mapping \( q \) to \( q^{-1} \).

If we apply either relation to the loop wrapping a cylinder and one fully degenerate puncture near it, there appear two kinds of knots. One winds around the cylinder by one time as it goes from \( C_{in} \) to \( C_{out} \) and the other does in the opposite way. Recalling the fact that there lives a 2D \( \mathcal{N}=(2,2) U(1) \) gauged linear \( \sigma \) model on the surface defect labelled by \( \square \) \textsuperscript{32, 56}, it is expected that these loops in \( M \) represent the \( U(1) \) Wilson loops charged \( \pm 1 \) according to the winding orientation, in the 2D system on the surface defect.

**General case**

How do the similar relations look like for any pair \( S = \wedge^\ell \square \) and \( R = \wedge^k \square \) ? From the above examples, we can expect that the general skein relations are

\[
\ell \otimes 1 = q^{k \ell} \sum_{s=0}^{\min(k,\ell)} q^{-s} 1
\] (3.20)
where the coefficients are the same as those of the crossing resolution \((3.1)\). The other relations are

\[
\ell \quad = \quad q^{-k_{\ell} N} \sum_{s=0}^{\min(k,\ell)} q^{s}.
\]

(3.21)

In the case of \(\ell = 1\), each reduces into \((3.17)\) or \((3.18)\). We see in the next subsection 3.4 that these relations are indeed reproduced in another approach.

### 3.4 Other projections

The requirement of the topological property of networks in \(M\) means that their projection onto a 2D plane can be taken arbitrarily. So far we have used \(C\)-projection, but actually, we can consider other projections onto a plane extending along \(I_H\)-direction. We call those projections “\(H\)-projections”.

Now it is possible to directly obtain the same result as before by applying the skein relation in a \(H\)-projection. Let us view the crossing network on the left hand side in \((3.21)\) from the right hand and apply the crossing resolution on the new projection. This can be expressed as

\[
\ell \quad = \quad q^{-k_{\ell} N} \sum_{s=0}^{\min(k,\ell)} q^{-s}.
\]

(3.22)

This relation exactly matches with the previous expressions \((3.21)\) and we have a relation between distinct projections like

\[
\ell \quad = \quad q^{-k_{\ell} N} \sum_{s=0}^{\min(k,\ell)} q^{-s}.
\]

(3.23)

where the left hand side is the usual \(C\)-projection but the right one is a \(H\)-projection including \(I_H\) direction.
Finally, we make a brief comment on the reproduction of the relation \((3.7)\). This can be geometrically expressed as

\[
S_R \bigcirc = \sigma_R \chi_R(q^{-\rho - \lambda_S}) S_R \bigcirc \tag{3.24}
\]

or locally

\[
S_R \bigcirc = \sigma_R \chi_R(q^{-\rho - \lambda_S}) \bigcirc \bigcirc \tag{3.25}
\]

We can derive this relation in some simple cases.

4 Proposal for punctured network defects

We have independently discussed the computations of expectation values for closed network and the geometrical structures of the composite surface-line systems and here we will unify two things. In Sec. 4.1, we compare the previous new skein relations with the computation of \(q\)-deformed Yang-Mills expectation values or the Schur indices. From the comparison, we can extract the operator action of some punctured networks. Based on this discussion, in Sec. 4.2, we propose the modified formula for general punctured networks and interpret the modification as the addition of the local Boltzmann factors assigned with dual arrowed edges.

4.1 Coexistence of closed network and isolated punctures

In this section, let \(C\) be a two-sphere with several punctures and \(\gamma\) be a 2D Wilson loop wrapping a tube in \(C\). This is the same situation as discussed in part 3 in Sec. 2.2. The general set-up can be discussed in the similar way. Recalling the discussion around \((2.9)\), let us cut along \(\gamma\) and decompose the Riemann surface \(C\) into the two parts which we call \(C_A\) and \(C_B\) here. In the following, we see the operator structure in two distinct basis.

Fugacity/Holonomy basis

The formula \((2.9)\) says that the whole partition function is given by

\[
\oint [da] I_{C_A}(a, \ldots) \chi_M(a) I_{C_B}(a^{-1}, \ldots). \tag{4.1}
\]
Now let us add a surface defect labelled by $S$. There are two choices of its addition, namely, the fully degenerate puncture on $C_A$ or on $C_B$ as shown in Fig. 12.

They are evaluated as

$$I_{C_A \cup W_M(C_B,S)} := \oint [da] I_{C_A}(a,\ldots) \chi_M(a) (\widehat{\mathcal{F}}S I_{C_B})(a^{-1},\ldots)$$  \hspace{1cm} (4.2)

and

$$I_{(C_A,S) \cup W_M(C_B)} := \oint [da] (\widehat{\mathcal{F}}S I_{C_A})(a,\ldots) \chi_M(a) I_{C_B}(a^{-1},\ldots)$$

$$= \oint [da] I_{C_A}(a,\ldots) \widehat{\mathcal{F}}S (\chi_M(a) I_{C_B})(a^{-1},\ldots)$$  \hspace{1cm} (4.3)

where we use the self-adjoint property of the difference operator $\widehat{\mathcal{F}}S$. And two expressions give different answers.

In particular, the special case $M = \wedge^\ell \Box$ and $S = \wedge^k \Box$ is important. Let $\Pi(R)$ be the set of weights for an irreducible representation $R$ and we also introduce a subset defined as

$$\Pi(\wedge^k \Box, \wedge^\ell \Box) := \{ (\lambda,\mu) \in \Pi(\wedge^k \Box) \times \Pi(\wedge^\ell \Box) \mid (\lambda,\mu) = s - k\ell N \}.$$  \hspace{1cm} (4.5)

In the following network representations in this subsection, we identify two end points of any open edge in networks such that they once wrap a tube in $C$.

On one side, we have a relation like

$$k^{\ell} \leftrightarrow \hat{W}_{\wedge^k \Box, \wedge^\ell \Box} = \sum_{\lambda \in \Pi(\wedge^k \Box)} \sum_{\mu \in \Pi(\wedge^\ell \Box)} a^\lambda \hat{\Delta}_\mu = \sum_{s=0}^{\min(k,\ell)} \frac{k \ell}{N} \hat{\Theta}_s^{(k,\ell)}$$  \hspace{1cm} (4.6)

where we have defined new difference operators conjugate to $\hat{\Delta}_\lambda$

$$\hat{\Delta}_\lambda := (\Delta_{\text{Haar}}(a))^{-1} \cdot \hat{\Delta}_\lambda \cdot (\sqrt{\Delta_{\text{Haar}}(a)})$$  \hspace{1cm} (4.7)
and another difference operator

\[ \hat{\delta}^{(k,\ell)}_s := \sum_{(\lambda,\mu) \in \Pi(\wedge^k \Box, \wedge^\ell \Box)_s} a^{\lambda/2} \Delta \chi_\mu a^{\lambda/2} = \sum_{(\lambda,\mu) \in \Pi(\wedge^k \Box, \wedge^\ell \Box)_s} q_{N}^{-s} a^{\lambda} \Delta \chi_{-\mu}. \] (4.8)

We also use the formula

\[ a^{\lambda} \Delta_{-\mu} = q_{2}^{(\lambda,\mu)} \Delta_{-\mu} a^{\lambda} \quad a^{\lambda} \Delta_{-\mu} = q_{2}^{(\lambda,\mu)} \Delta_{-\mu} a^{\lambda}. \] (4.9)

On the other hand, we have

\[ k \ell \longleftrightarrow \hat{\mathcal{S}}_{\wedge^k \Box} \hat{W}_{\wedge^\ell \Box} = \sum_{\lambda \in \Pi(\wedge^k \Box)} \Delta_{-\mu} a^{\lambda} = \sum_{s=0}^{\min(k,\ell)} q_{N}^{s} \hat{\delta}^{(k,\ell)}_s. \] (4.10)

Comparing (3.20) and (3.21) with these results, we naturally get the correspondence

\[ k \ell \longleftrightarrow \hat{\delta}^{(k,\ell)}_s. \] (4.11)

In the special case \( s = k = \ell \), we have

\[ k \longleftrightarrow \hat{\delta}^{(k,k)}_k = q_{-1}^{k(N-k)} \sum_{\lambda \in \Pi(\wedge^k \Box)} a^{\lambda} \Delta_{-\lambda}. \] (4.12)

**Representation basis**

We repeat the same analysis in another new basis. For that purpose, let us expand the partition functions on \( C_A \) and \( C_B \) by the \( SU(N) \) characters as

\[ \mathcal{F}_{RA}(\{b\}) := \oint [da'] \chi_{RA}(a'^{-1}) I_{C_A}(a', \{b\}) \] (4.13)

\[ \mathcal{G}_{RB}(\{c\}) := \oint [da'] \chi_{RB}(a'^{-1}) I_{C_B}(a', \{b\}) \] (4.14)
and then we can express the expectation value of the Wilson loop in the representation $M$ as

$$\langle F|\hat{W}_M|G\rangle := \sum_{R_A, R_B} \oint [da] \chi_{R_A}(a^{-1}) F_{R_A}(\{b\}) \chi_M(a) \chi_{R_B}(a) G_{R_B}(\{c\}). \quad (4.15)$$

where we introduced a matrix representation like

$$|F\rangle = \sum_{R} F_{R}(\{b\}) |R\rangle \quad (4.16)$$

$$|G\rangle = \sum_{R} G_{R}(\{c\}) |R\rangle \quad (4.17)$$

$$\langle R_1|R_2\rangle = \delta_{R_1,R_2} \quad \text{orthonormal basis. (4.18)}$$

Using the eigenvalues of difference operators (3.6), the addition of surface operators in this basis corresponding to (4.2) and (4.4) are expressed as

$$\langle F|\hat{W}_M \hat{\mathcal{S}}|G\rangle = \sum_{R_A, R_B} N_{R_B}^{R_A} F_{R_A}(\{b\}) \bar{E}_{R_B}(\{c\}) \quad (4.19)$$

$$\langle F|\hat{\mathcal{S}} \hat{W}_M|G\rangle = \sum_{R_A, R_B} N_{R_B}^{R_A} E_{R_A}(\{b\}) G_{R_B}(\{c\}), \quad (4.20)$$

respectively. Note that 4D Wilson loops act as “difference operators” and 4D surface defects do as diagonal multiplications in this basis.

When $M = \wedge^\ell \Box$ and $S = \wedge^k \Box$, we can also repeat the similar computation to the previous one. First of all, let us rewrite the eigenvalue $\bar{E}_R^{(S)}$ by using (3.6) into

$$\bar{E}_R^{(S)} = \sum_{L} q^{-2\sum_{i\in L}(\rho+\lambda_R)_i} = \sum_{L} q^{-2(\rho+\lambda_R,h_L)} \quad (4.21)$$

where $L$ runs over all the $\ell$-element subsets of $\{1, 2, \ldots, N\}$. Next, the sum including the Littlewood-Richmond coefficient can be written as follows.

$$\sum_{R_A, R_B} N_{R_B}^{R_A} \wedge^{\ell-k}\Box = \sum_{\lambda_{R_B}} \sum_{K} \quad (4.22)$$

where $\lambda_{R_A} - \lambda_{R_B} = \sum_{i\in K} h_i =: h_K \in \Pi(\wedge^k \Box)$ and $K$ runs over all the $k$-element subsets of $\{1, 2, \ldots, N\}$.

Now (4.20) leads to

$$\langle F|\hat{\mathcal{S}} \hat{W}_M|G\rangle = \sum_{\lambda_B} \sum_{K,L} q^{2(\rho+\lambda_B+h_K,h_L)} F_{R(\lambda_B+h_K)}(\{b\}) G_{R(\lambda_B)}(\{c\}) \quad (4.23)$$

30
\[ \begin{align*}
&= \sum_{s=0}^{\min(k,\ell)} q^{-2s}\left(s - \frac{k\ell}{N}\right) \sum_{\lambda_B \geq 0} \sum_{K,L} q^{-2(\rho + \lambda_B,h_L)} \mathcal{F}_{R(\lambda_B+h_K)}(\{b\}) \mathcal{G}_{R(\lambda_B)}(\{c\}) \\
&\quad \times \left(\frac{k\ell}{N}\right)^{s-\min(k,\ell)} N^{-\lambda_B} \sum_{|K\cap L| = s} H_{R(\lambda_B)}(\{c\}) \mathcal{G}_{R(\lambda_B)}(\{c\})
\end{align*} \]

(4.24)
(4.25)

where we use \((h_K, h_L) = \sum_{(i,j) \in K \times L} (h_i, h_j) = |K \cap L| - \frac{k\ell}{N}\) in the second line and \(\lambda \geq 0\) means that it is a dominant weight, that is to say, \(\lambda_\alpha \geq 0\) for all \(\alpha\). By evaluating (4.19) in the same way, we have the similar correspondence

\[ R_A \leftrightarrow \sum_K \delta_{\lambda_A - \lambda_B,h_K} q^{-(2\rho + \lambda_B + \lambda_A,h_L)} \]

(4.26)

which is the dual expression of the operator \(\hat{O}_s^{(k,\ell)}\).

Setting \(s = k = \ell\), we finally get the following one needed later soon.

\[ R_A \leftrightarrow \sum_K \delta_{\lambda_A - \lambda_B,h_K} q^{-(2\rho + \lambda_B + \lambda_A,h_L)} \]

(4.27)

### 4.2 Modified formula

After performing the crossing resolutions, there appear several networks allowing the punctured edges as shown in Fig. 13.

\[ R_A \leftrightarrow \sum_K \delta_{\lambda_A - \lambda_B,h_K} q^{-(2\rho + \lambda_B + \lambda_A,h_L)} \]

(4.27)

Figure 13: Punctured edge.

The modification of the statistical model previously introduced in Sec. 2.3 is simple : add another local Boltzmann factor for pairs of two adjacent dominant weights or,
equivalently, edges. The last result (4.27) in the previous section suggests that this factor is given by

$$B_{\lambda_A,\lambda_B}^n = q^{-n(2\rho + \lambda_A + \lambda_B - \lambda_B)} = q^{-n(\tilde{\lambda}_A + \tilde{\lambda}_B, \tilde{\lambda}_A - \tilde{\lambda}_B)}$$

where $n$ is the number of “punctured” on the edge and $\tilde{\lambda} := \lambda + \rho$.

As a simple application, we can see a new but naturally expected skein relation like

$$b \quad a \quad R_A \quad R_B \quad R_C = b \quad a \quad R_A \quad R_B \quad R_C$$

(4.29)

because of the following equality

$$q^{-(\tilde{\lambda}_A + \tilde{\lambda}_C, \tilde{\lambda}_A - \tilde{\lambda}_C)} = q^{-(\tilde{\lambda}_A + \tilde{\lambda}_B, \tilde{\lambda}_A - \tilde{\lambda}_B)} q^{-(\tilde{\lambda}_B + \tilde{\lambda}_C, \tilde{\lambda}_B - \tilde{\lambda}_C)}.$$

(4.30)

It is the interesting problem to prove the equalities (3.20) or (3.21) based on the dual statistical model but we have no proof for them in general cases yet.

5 Summary and discussion

In this paper, we propose the conjectural computational procedures for the general closed and punctured network defects in the 2D $q$-deformed Yang-Mills theory. Such networks are geometrically knots with junctions in the three dimensional space which includes $C$ and one of 4D directions and expected to be the counterparts of composite surface-line systems in 4D.

Now we list several problems to be solved in future. In the gauge theory perspective, it is necessary to discuss the 4D descriptions of the composite surface-line systems and compare the SCIs with the expectation values. The 4D line operators are bounded to the surface operators and expected to be some interfaces including 2D Wilson lines of the two dimensional $\mathcal{N}=(2,2)$ gauged linear sigma models [90, 92]. On the other hand, since the three geometry is encoded in 5D space, it is possible to describe them based on 5D SYM language like [93]. It is also interesting to relate them to the well-known 3D-3D correspondence story [24, 94] where the 3D $\mathcal{N}=2$ gauge theories on $S^3$ and complex Chern-Simons theories on hyperbolic spaces are related. More additions of defects in this correspondence were also discussed in [95], for example.

There are still several generalizations in this set-up. One thing is to define and to incorporate general open networks [66] which are composite systems of codimension two and four defects. Other is the extension to general simple Lie algebras (simply-laced in the context of class S), in particular $D$-series [96, 97] or in the presence of twisted lines.
in $A_{2N-1}$-series. Finally, although it is expected that the finite area extension is straightforward, are there interesting applications?

There are also several mathematical problems: the justification of global symmetry enhancement in all order $q$ expansion in Sec. 2.4, skein relations in the presence of general punctures, reproduction of $q = 1$ limit results where there is the unambiguous definition of Wilson networks, more on quantum groups behind and relations to integrable models as remarked in Sec. 2.5. The relation to higher Teichmüller space structure or Liouville-Toda analysis is also interesting because the local information of OPEs are expected to be same in both $S^1_b$ and $S^1 \times q S^3$ systems.

Acknowledgements The author would like to gratefully thank Yuji Tachikawa for many discussions on trying to define Wilson networks based on quantum group and making several comments on his draft. He also wishes to thank the kind hospitality by the staffs of Perimeter Institute for theoretical physics where he had finished writing this draft, and great members there, in particular, Jaume Gomis, Davide Gaiotto, Shota Komatsu and Hee-Cheol Kim, for making his visit fruitful and several discussions. He would like to thank Takuya Okuda, Masahito Yamazaki and Kentaro Hori for various discussions on this theme and finally sofas at Kavli IPMU and Perimeter Institute for relaxing him to advance this research. A More mathematics on the dual model

Here we develop some useful tools to compute the local Boltzmann factor $B^\triangle$ using and to prove some skein relations in App.[B]. First of all, recall the notations of Lie algebras and their representations. Consider the case that the Lie algebra is $\mathfrak{su}(N)$. $R(\lambda)$ denotes the irreducible representation associated with a dominant weight $\lambda$, $\lambda_R$ does the dominant weight to $R$ conversely and $\Pi(R)$ does the set of weights in $R$. $\omega_\alpha$ for $\alpha = 1, 2, ..., N - 1$ are fundamental weights, $h_i$ for $i = 1, 2, ..., N$ are weights in $\Pi(R(\omega_1) = \square)$ and there are relations between two as $h_a = \omega_a - \omega_{a-1}$ where $\omega_N = \omega_0 = 0$. We also use the standard metric in weight vectors determined by $h_i = e_i - \frac{1}{N} \sum_{i=1}^{N} e_i$ and $(e_i, e_j) = \delta_{i,j}$.

A.1 Definitions

Let us start by repeating some definitions which appeared in Sec. 2.3.2. We introduced a mathematical object which we call “pyramid”. This is just an assembly of integers designated by two labels $h$ and $\alpha = \alpha_h$. $h$ runs over $1, 2, ..., N - 1$

\textsuperscript{20}The perfect order of the indices of $h_i$ is determined by the partial order in the weight lattice.
and $\alpha$ does over $1, 2, \ldots, N - h$ for each $h$. Therefore, this object consists of $\frac{1}{2}N(N - 1)$ integers. There is an inclusion of weights into the pyramid as follows:

$$\hat{\lambda}_{h,\alpha} := \sum_{\beta=0}^{\alpha+h-1} \lambda_{\beta}$$  \hspace{1cm} (A.1)

where $\lambda = \sum_{\beta=1}^{N-1} \lambda_{\beta}\omega_{\beta}$. We also use the same symbol $\hat{\lambda}$ for the pyramids not in the image of this inclusion map. In such cases, $\hat{\lambda}$ is considered as a single symbol as a whole and $\lambda$ is meaningless. Note that the addition can be defined as

$$(c_1\hat{s}_1 + c_2\hat{s}_2)_{h,\alpha} := c_1(\hat{s}_1)_{h,\alpha} + c_2(\hat{s}_2)_{h,\alpha}$$  \hspace{1cm} (A.2)

which is consistent with the above inclusion map in the sense that it preserves the original additional structure in the weight vector space. 0 is the identity element of this operation. There can be also a product defined as

$$(\hat{s}_1 * \hat{s}_2)_{h,\alpha} := (\hat{s}_1)_{h,\alpha}(\hat{s}_2)_{h,\alpha}$$.  \hspace{1cm} (A.3)

The distributive property is obvious.

We also defined two functions:

1. **(2.17)** majority function $m_j$ for three variables:

$$m_j(a, b, c) := \begin{cases} a & b = a \text{ or } c = a \\ b & a = b \text{ or } c = b \\ c & a = c \text{ or } b = c \end{cases}$$  \hspace{1cm} (A.4)

and

$$m_j(\hat{\lambda}_1, \hat{\lambda}_2, \hat{\lambda}_3) := \{m_j((\hat{\lambda}_1)_{h,\alpha}, (\hat{\lambda}_2)_{h,\alpha}, (\hat{\lambda}_3)_{h,\alpha})\}_{h,\alpha}$$  \hspace{1cm} (A.5)

As there appears no case that all variables are distinct, this definition is well-defined in our usage.

2. **(2.19)** $q$-dimension function $D$:

$$D[\hat{\lambda}] := \prod_{h=1}^{N-1} \prod_{\alpha=1}^{N-h} \frac{[(\hat{\lambda})_{h,\alpha} + h]_q}{[h]_q}$$  \hspace{1cm} (A.6)

and there is a simple relation to the ordinary $q$-dimension as

$$\dim_q R(\lambda) = D[\hat{\lambda}]$$  \hspace{1cm} (A.7)
where $\hat{\lambda}$ is the natural inclusion into the pyramid of the dominant weight $\lambda$.

Finally, let us introduce following pyramids defined for any two subsets $I, J$ of $\{1, 2, \ldots, N\}$ satisfying $I \cap J = \emptyset$:

$$
\hat{f}_{I,J} := m_J(0, -\hat{h}_I, \hat{h}_J) \quad (A.8)
$$

where $h_I := \sum_{i \in I} h_i$. They have equivalent definitions

$$
(\hat{f}_{I,J})_{h,\alpha} := \begin{cases} +1 & \text{if } \alpha \in J \text{ and } \alpha + h \in I \\ -1 & \text{if } \alpha \in I \text{ and } \alpha + h \in J \\ 0 & \text{otherwise} \end{cases} \quad (A.9)
$$

or

$$
(\hat{f}_{I,J})_{h,\alpha} := \sum_{i \in I,j \in J} \text{sgn}(i - j)\delta_{h,|i-j|}\delta_{h,\text{min}(i,j)} \quad (A.10)
$$

where $\delta$ is the ordinary Kronecker’s $\delta$ symbol.

These pyramids satisfy the following properties:

$$
\hat{f}_{I,J} = -\hat{f}_{J,I} \quad \text{skewsymmetric} \quad (A.11)
$$

$$
\hat{f}_{I,J \sqcup K} = \hat{f}_{I,J} + \hat{f}_{I,K} \quad \text{linearity} \quad (A.12)
$$

$$
\hat{h}_J = \hat{f}_{J,J} \quad (A.13)
$$

A.2 Convenient formulae

Now let us start the argument recalling the discussion in Sec.2.3.1. Consider three regions called $A, B$ and $C$ clockwise around a trivalent junction and denote their dominant weights $\lambda_A, \lambda_B$ and $\lambda_C$. See Fig.6 in Sec.2.3.1. We also denote the outgoing charge associated with the edge between the regions $X$ and $Y$ by $a_{XY}$ for $(X, Y) = (A, B), (B, C)$ and $(C, A)$.

We define the following objects in order.

$$
\lambda_{XY} := \lambda_X - \lambda_Y =: \sum_{\alpha=1}^{N-1} \lambda_X^\alpha \omega_\alpha =: \sum_{s=1}^{N} \lambda_{XY}^s h_s. \quad (A.14)
$$

$\lambda_{XY}^s$ is not uniquely determined due to the condition $\sum_{s} h_s = 0$ in the root vector space. But it is uniquely determined if we impose the conditions $\lambda_{XY}^s \geq 0$ and $\exists s \lambda_{XY}^s = 0$.

We can find that $\lambda_{XY}^s$ is either 1 or 0 and define $E_{XY} := \{s \in \{1, 2, \ldots, N\} | \lambda_{XY}^s = 1\}$ where $|E_{XY}| = a_{XY}$ follows and $\overline{E_{XY}} := \{1, 2, \ldots, N\} \setminus E_{XY} = E_{YX}$. The cycle condition $\lambda_{AB} + \lambda_{BC} + \lambda_{CA} = 0$ tells us $E_{AB} \sqcup E_{BC} \sqcup E_{CA} = \{1, 2, \ldots, N\}$ (disjoint union). Now we have

$$
m_J(\lambda_A, \lambda_B, \lambda_C) = \hat{\lambda}_A + \hat{f}_{E_{AB}, E_{CA}} \quad (A.15)
$$
and we obtain two other similar expressions by permuting the above cyclically as $A \rightarrow B \rightarrow C \rightarrow A$. This formula will turn out to be useful in the next section.

Finally, we list a few propositions also used later.

1. 

$$D[\hat{x} + \hat{z}]D[\hat{y}] = D[\hat{x}]D[\hat{y} + \hat{z}] \text{ when } (\hat{x} - \hat{y}) \ast \hat{z} = \hat{0}.$$  

(A.16)

Each element in pyramid satisfies $x = (\hat{x})_{h,\alpha} = (\hat{y})_{h,\alpha} = y$ or $z = (\hat{z})_{h,\alpha} = 0$ and then we can say $[x + z]_q[y]_q = [x]_q[y + z]_q$ for any $(h : \alpha)$.

2. 

$$\hat{f}_{I,J} \ast \hat{f}_{K,L} = \hat{0} \text{ for } (I \sqcup J) \cap (K \sqcup L) = \phi$$  

(A.17)

Using $(\hat{f}_{P,Q})_{h,\alpha} = 0$ for $\alpha \notin P \sqcup Q$, this statement holds true.

3. 

$$\hat{f}_{I,J} \ast \hat{f}_{I,K} = \hat{0} \text{ for } J \cap K = \phi$$  

(A.18)

Assume $(\hat{f}_{I,J})_{h,\alpha} \neq 0$ and $(\hat{f}_{I,K})_{h,\alpha} \neq 0$ for some common $(h : \alpha)$. If $\alpha \in I$, we have $\alpha + h \in J$ and $\alpha + h \in K$ but it is impossible by definition and we say $J \cap K = \phi$. This is same for the case $\alpha + h \in I$. So the assumption is always false and the above statement is true.

Note that there is a more general formula including last two propositions:

$$\hat{f}_{I,J} \ast \hat{f}_{K,L} = (\hat{f}_{I \cap K,J \cap L})^2 - (\hat{f}_{I \cap L,J \cap K})^2$$  

(A.19)

where $\hat{x}^2 := \hat{x} \ast \hat{x}$.

**B Derivation of several skein relations**

Based on our proposal for the local Boltzmann factor (2.20), we prove elementary skein relations in this appendix.

**B.1 Associativity**

The associativity skein relation is given by

$$R_B \quad p \quad R_C \quad v \quad R_D \quad = \quad R_B \quad p \quad R_C \quad v \quad R_D .$$  

(B.1)
Here \( s = p + q = v - r, \) \( t = q + r = v - p \) and \( v = p + q + r \). Their dual triangle quivers are given as

\[
\begin{align*}
&\begin{array}{c}
P \quad \lambda_C \\
\lambda_B
\end{array} \\
&\begin{array}{c}
Q \\
\lambda_A
\end{array} \\
&\begin{array}{c}
P \square Q \square R \\
\lambda_D
\end{array}
\quad = \quad
\begin{array}{c}
P \quad \lambda_C \\
\lambda_B
\end{array} \\
&\begin{array}{c}
Q \\
\lambda_A
\end{array} \\
&\begin{array}{c}
P \square Q \square R \\
\lambda_D
\end{array}
\end{align*}
\]

which is the flip of the triangulations. We have introduced here \( P := E_{CB}, Q := E_{BA}, \) and \( R := E_{AD} \). (A.15) tells that the local Boltzmann factors’ expression associated with this equality is equivalent to

\[
D[\hat{\lambda}_B + \hat{f}_{Q,P}]^{-1/2}D[\hat{\lambda}_A + \hat{f}_{R,P,Q}]^{-1/2} = D[\hat{\lambda}_B + \hat{f}_{Q,R,P}]^{-1/2}D[\hat{\lambda}_A + \hat{f}_{R,Q}]^{-1/2}
\]

(B.3)

for any \( \lambda_A, \lambda_B, \lambda_C \) and \( \lambda_D \). In the following, we prove this equality.

Introduce \( \hat{x} := \hat{\lambda}_B + \hat{f}_{Q,P} \) and \( \hat{y} := \hat{\lambda}_A + \hat{f}_{R,Q} \). Now we get

\[
\begin{align*}
(l.h.s)^{-2} & = D[\hat{x}]D[\hat{y} + \hat{f}_{R,P}] \\
(r.h.s)^{-2} & = D[\hat{x} + \hat{f}_{R,P}]D[\hat{y}].
\end{align*}
\]

(B.4) \hspace{1cm} (B.5)

To apply the proposition (A.16) to the above, it is enough to check \( (\hat{x} - \hat{y}) \ast \hat{f}_{R,P} = \hat{0} \). Since \( \lambda_B - \lambda_A = h_Q = \hat{f}_{Q,Q} \),

\[
(\hat{x} - \hat{y}) \ast \hat{f}_{R,P} = (\hat{f}_{Q,Q} + \hat{f}_{Q,P} + \hat{f}_{R,Q}) \ast \hat{f}_{R,P} = (2\hat{f}_{R,Q} + \hat{f}_{P \square Q \square R,Q}) \ast \hat{f}_{R,P} = \hat{0}
\]

(B.6) \hspace{1cm} (B.7)

where we have used the two propositions (A.17) and (A.18) in the last line. Now we have proved the expected equality.

### B.2 Digon contractions

There is more non-trivial skein relations what we call digon contractions as shown below.

\[
\begin{array}{c}
a + b \\
\circlearrowright
\end{array} \\
\begin{array}{c}
R_A \\
\circlearrowleft
\end{array} \\
\begin{array}{c}
a + b \\
\circlearrowright
\end{array} \\
\begin{array}{c}
\circlearrowleft
\end{array}
\]

\[
\begin{array}{c}
\frac{[a + b]_q!}{[a]_q![b]_q!} \\
\circlearrowleft
\end{array} \\
\begin{array}{c}
R_A \\
\circlearrowleft
\end{array} \\
\begin{array}{c}
a + b \\
\circlearrowright
\end{array} \\
\begin{array}{c}
\circlearrowleft
\end{array}
\]

(B.8)

where \( [n]_q := \prod_{i=1}^{n}[i]_q \) for a positive integer \( n \).

First of all, let us introduce several definitions. For fixed \( E_{AB} \), we define a natural embedding

\[
\ell^{-1} : \{1, 2, \ldots, a + b\} \xrightarrow{\text{bijec.}} E_{AB}
\]

(B.9)
\[ \ell^{-1}_\gamma := \ell^{-1}(\gamma) \quad \text{for} \quad \gamma \in \{1, 2, \ldots, a + b\} \quad \ell_i := \ell(i) \quad \text{for} \quad i \in E_{AB} \] (B.10)

satisfying that \( 1 \leq \ell^{-1}_1 < \ell^{-1}_\gamma \leq N \) for \( 1 \leq \gamma < \gamma' \leq a + b \).

\[ M := \{(\ell^{-1}_\gamma, \ell^{-1}_\gamma) \mid \text{for any } \gamma' > \gamma \}. \] (B.11)

By definition, for any two subsets \( I, J (I \cap J = \phi) \) of \( E_{AB} \), it is true that \((\hat{f}_{I,J})_{h,\alpha} \neq 0 \iff (h, \alpha) \in M \).

Next, let \( \hat{M} \) be the index set of the pyramid for \( SU(a + b) \) weights. In other words, for \((\hat{h} : \hat{\alpha}) \in \hat{M}, \hat{h} \) runs over \( 1 \) to \( a + b - 1 \) and \( \hat{\alpha} \) does over \( 1 \) to \( a + b - \hat{h} \). The map \( \ell \) induces a new bijection map \( \hat{\ell} \) from \( M \) to \( \hat{M} \) as follows.

\[ (h : \alpha) := \hat{\ell}(h, \alpha) := (\ell_{\alpha + \hat{h}} - \ell_\alpha : \ell_\alpha) \] (B.12)

If we label the representation assigned to the inside region of the digon as \( S \), the left hand side gives

\[ \sum_S \frac{\dim_S S}{D[m_j(\lambda_A, \lambda_B, \lambda_S)]} = \sum_{I : E_{SB} \subseteq E_{AB}} \frac{D[\hat{\lambda}_B + \hat{h}_I]}{D[\hat{\lambda}_B + \hat{f}_{E_{BA}, I}]} \] (B.13)

\[ = \sum_{I \subseteq E_{AB}, |I| = b} \frac{D[\hat{\lambda}_B + \hat{f}_{E_{BA}, I} + \hat{f}_{E_{AS}, I}]}{D[\hat{\lambda}_B + \hat{f}_{E_{BA}, I}]} = \sum_{I \subseteq E_{AB}, |I| = b} \frac{D[\hat{\lambda}_B + \hat{f}_{E_{AS}, I}]}{D[\hat{\lambda}_B]} \] (B.14)

\[ = \sum_{I \subseteq E_{AB}, \{h, \alpha\} \in \hat{M}} \prod_{|I| = b} \frac{[(\hat{\lambda}_B + \hat{f}_{E_{AS}, I})_{h,\alpha} + \hat{h}_I]}{[\hat{\lambda}_B + \hat{h}_I]} = \sum_{I \subseteq E_{AB}, \{h, \alpha\} \in \hat{M}} \prod_{|I| = b} \frac{[\hat{\mu}_{h,\alpha} + (\hat{f}_{E_{AS}, I})_{\ell^{-1}(h,\alpha) + \hat{h}_I}]}{[\hat{\mu}_{h,\alpha} + \hat{h}_I]} \] (B.15)

where we have used \( h_I = \hat{f}_{I, I}, I = E_{BA} \cup E_{AS} \) and the proposition (A.16) using also (A.18) \( \hat{f}_{E_{BA}, I} \ast \hat{f}_{E_{AS}, I} = \hat{0} \). In the 3rd line, we have used \((\hat{f}_{E_{AS}, I})_{h,\alpha} = 0 \) for \((h, \alpha) \notin \hat{M} \) and \( \hat{M} \cong \hat{M} \) and redefined \( \hat{\mu}_{h,\alpha} := (\hat{\lambda}_B)_{\ell^{-1}(h,\alpha)} + \hat{h}_I \) where \( h = h(\hat{h}, \hat{\alpha}) = \ell^{-1}_{\hat{h} + \hat{\alpha}} - \ell^{-1}_{\alpha} \).

Now what we should prove are two following equations.

\[ \sum_{\beta = \hat{\alpha}}^{\hat{\alpha} + h - 1} \hat{\mu}_{1; \beta} = \hat{\mu}_{h,\alpha} \] (B.16)

\[ (h_{\ell(I)}^{SU(a+b)})_{h,\alpha} = (\hat{f}_{E_{AS}, I})_{\ell^{-1}(h,\alpha)} \] (B.17)

The former equality says that \( \hat{\mu} \) is the image of a weight \( \mu \) in the pyramid and follows from the direct computation based on the above definitions. The latter one means that \( \hat{f}_{E_{AS}, I} \) gives an image of a weight in \( \Pi(\land^b \square) \) of \( SU(a + b) \), and it also readily follows from the equality

\[ (h_{\ell(I)}^{SU(a+b)})_{h,\alpha} = (\hat{f}_{E_{AB} \setminus I, I})_{\ell^{-1}_{\alpha + h} - \ell^{-1}_{\alpha} : \ell^{-1}_I}. \] (B.18)
In conclusion, the numerator in (B.15) equals to the $q$-dimension of the $SU(a+b)$ irreducible representation $R(\mu + h_{\ell(I)})$ up to the common factor $\prod_{(h,\alpha)} [\hat{h}]_q$ and, the sum over all the $b$ element subsets of $E_{AB}$ equals to all irreducible representations appearing in the tensor product of $R(\mu)$ and $\wedge^b \square$. Therefore, this gives $\dim_{SU(a+b)} \wedge^b \square$ which exactly reproduces the prefactor in the right hand of (B.8).

C General charge/network correspondence

This appendix is a complement of the paper [55]. There we see the one-to-one mapping between the charge lattice for $\mathcal{N}=4$ $\mathfrak{su}(3)$ theory proposed by Kapustin [21] and $A_2$ networks on the 2-torus and also show several examples for $A_{N-1}$ cases in the appendix. However, we did not explain the dictionary in detail. Here we state the mapping for general $A_N$. This is a minimal extension of a work for general $A_1$ class S theories [38].

The generalization and refinement to general class S theories are interesting future problems. Note that the following relations can hold true in the Liouville-Toda CFTs and also that the expectation values vanish in the 2D $q$-deformed Yang-Mills when their electric/magnetic weights are not in the root lattices as explained in part 3 in Sec. 2.2.

C.1 Useful symbol

Here we introduce a useful symbol expressing an element of $\mathfrak{su}(N)$ Wilson-‘t Hooft loop charge lattice $(\Lambda_{mw} \times \Lambda_{wt})/\mathcal{W}_{\mathfrak{su}(N)}$ where $\Lambda_{mw}$, $\Lambda_{wt}$ and $\mathcal{W}_{\mathfrak{su}(N)}$ are the magnetic weight lattice, the weight lattice and the Weyl reflection group, respectively. Be aware that $\Lambda_{mw} \simeq \Lambda_{wt}$ for $\mathfrak{su}(N)$ and then we use the same basis. For a given pair of $(\mu, \lambda)$, it is always possible to take $\mu$ into a dominant weight $\mu'$ using a Weyl reflection. According to this operation, $\lambda$ is also mapped into an element $\lambda'$ which is not always uniquely determined. There, we have a Young diagram $Y_M$ associated with $\mu'$. In the same way as (A.14), $\lambda'$ can be expanded with $h_s$ and we have unique elements $\lambda'^s$ ($s = 1, 2, \ldots, N$) which are non-negative integers. By putting $\lambda'^s$ boxes in the $s$-th row in the similar way as the ordinary Young diagrams, we have a diagram referred to as $Y_E$. Now, we make a new diagram which is a pair of the horizontally flipped and filled $Y_M$ and the diagram $Y_E$. See Fig. 14 below for examples.

C.2 Charge to network

For a given charge pair $(\mu, \lambda)$, let $M_i$ be subsets of $1, 2, \ldots, N$ so that there is a box in $Y_M$ specified by $i$-th column and $a$-th row only if $a \in M_i$. By replacing $Y_M$ by $Y_E$, we also define $E_i$ in the same way. Then, define $s_{pq}$ as the number of elements of $M_p \cap E_q$

\textsuperscript{21}Here we consider $\mathcal{N}=4$ SYM as the very special case of class S theories. The similar relations are expected to hold true in the $\mathcal{N}=2^*$ gauge theory but precise dictionaries are not established completely because there appears a flavor symmetry related to the hypermultiplet mass term.
Figure 14: Several examples for the relation between an element of the su(N) charge lattice (above) and its diagrammatic symbol (below).

and $Q_{(s)}^{pq}$ as an open network like

$$Q_{(s)}^{pq} \longleftrightarrow \begin{array}{c}
\text{p} \\
\text{s} \\
\text{q}
\end{array} \quad . \quad (C.1)$$

By using these, the BPS Wilson-'t Hooft line operator in $\mathcal{N}=4$ SU(N) SYM is geometrically represented by

$$\begin{array}{c}
\text{q} \\
Q_{(pq)}^{pq} \\
\text{p}
\end{array} \quad . \quad (C.2)$$

where edges are connected on any adjacent parallelograms and each pair of opposite edges is identified. Note also that this relation holds up to lower charges (see the beginning of Sec.4 in [55]). We show two examples.

The reversed operation can be done by computing the trace functions associated with the network because the trace function is a polynomial (allowing negative powers) of two $U(1)^N/U(1)$ fugacities along $\alpha$-cycle and $\beta$-cycle of the 2-torus.
